THE AUSTRIAN BRIER.

WHAT is the Austrian Brier, and whence did it come? These questions occurred to us in a singular way. Not long since a correspondent enquired about a yellow-flowered Rose occurring in Syria, where the profusion and beauty of the flowers were very noteworthy, as noted also on the slopes of Lebanon by Sir John Llewelyn. From the description given, we conjectured that the plant was the Rosa lutea of Miller, of the *Botanical Magazine* (tab. 303), and of Lindley's *Monograph of Roses* (1820, p. 84). This conjecture was verified by the inspection of Syrian specimens obtained subsequently by Mr. Arthur Sutton. This plant was called by Linnæus Rosa Eglanteria, a name adopted in the *Index Kewensis*, which is unfortunate for many reasons, which we need not discuss here. When the Syrian flowers just mentioned were subsequently submitted to Col. Prain, the Director of the Royal Gardens at Kew, he at once recognised them as those of an Indian Rose—R. Eglanteria of Linnæus, which is, as we have said, synonymous with R. lutea of Miller. It is described in Sir Joseph Hooker's *Flora of British India* (II., 1897, p. 360), and stated to be a native of the drier parts of the Himilayas from Kistwar westward, and in Western Tibet. Afghanistan, Asia Minor, and Siberia are also mentioned as countries wherein this Rose is found native. Hooker expressly calls this the Austrian Rose, and cites Jacquin, *Hort. Vindob*, I., t 1. Nicholson also calls it by this name. Sir Dietrich Brandis and Boissier both name it Rosa lutea. Boissier in his *Flora Orientalis* (II., 1872, p. 671), mentions the "Persian yellow" as possibly a form of this species (lutea), and in William Paul's *Rose Garden*, Rosa lutea is made to include the following varieties: Copper, double yellow, Harrisoni, a hybrid said to have been introduced from America, Persian Yellow, etc. In Gibelli's *Flora Italiana* (p. 677) Rosa lutea is mentioned as growing wild in hedges in Piedmont, Venice and Naples. Gremli, in his *Flora of Switzerland*, translated by Poitson, speaks of this species as apparently quite spontaneous on the gypseous rocks near Nax, Derasme, and *Naudin Manuel* (p. 102) remarks that it (lutea or Capucine) seems to be indigenous to the centre and south of Europe, where, however, it may be merely naturalised. Coste in his *Manual of the Flora of France* does not mention it, nor is it entered in the Belgian floras. Nyman in his *Conspectus Florae Europae* tells us that R. lutea has been mentioned as occurring in Southern Europe, but that it is there only sub-spontaneous. Lindley in his monograph above cited mentions a variety punicea, "floribus bicoloribus," which we mention because he cites as synonymous R sylvestris Austriaca, flore phoenicco, *Hort. Angl.* 66, 18, and R. lutea bicolor, Jacquin *Hort. Vind.*, t. t. 1.; *Sims Bot. Mag.*, t. 1077, and others which it is not necessary for our present purpose to enumerate. Crépin included the species lutea in his section Luteae. Baker in these columns, August 15, 1885, p. 199, kept up Miller's name of lutea and arranged it in his group Rubiginosae, but in his more recent revision in the *Journal of the Linnean Society*, February 16, 1905, he alters his opinion, adopts Linnæus' name of Eglanteria (giving Miller's name lutea as a synonym), and places it in his Group VII. Spinosissimae. We might pursue this part of the subject much more fully, but only at the risk of wearying the reader.

From what has been said it seems clear that Rosa lutea or the so-called Austrian Brier is of Eastern origin and that it is not really native in any part of Europe, though met with here and there in a naturalised condition. How it received the name Austrian is a mystery, though it is easy to conjecture that it may have been introduced from the Levant into Austria and distributed thence into Flanders in the 15th or 16th century. Thus Dodoens and Bauhin both speak of Rosa lutea, but we have not their works at hand to verify our reference. Matthiolus in his *Commentaries on Dioscorides* (1558) mentions Roses growing in Italy as conspicuous for their golden colour (quae aureo colore fulgent).

Our own Gerard, who is generally rather credulous, narrates the following story, but he publishes it with all reservations:—

"The yellow Rose which (as divers do report) was by Art so coloured, and altered from his first estate, by grafting a wilde Rose upon a Broome-stalke; whereby (say they) it doth not onely change his colour, but his smell and force. But for my part I having found the contrary by mine owne experience, cannot be induced to beleeue the report for the roots and off-springs of this Rose have brought forth yellow Roses, such as the maine stocke or mother bringeth out, which event is not to be seen in all other plants that have been graffed. Moreover, the seeds of yellow Roses have brought forth yellow Roses, such as the floure was from whence they were taken; which they should not do by any conjecturall reason, if that of themselves they were not a naturall kinde of Rose. Lastly, it were contrary to that true principle, *Natura sequitur femina quodque suae*: that is to say. Every seed and plant bringeth forth fruit like unto it selfe, both in shape and nature: but leaving that errour, I will proceed to the description: the yellow Rose hathe browne and prickly stalks or shoots, five or six cubits high, garnished with many leaves, like unto the Muske Rose, of an excellent sweet smell, and more pleasant than the leaves of the Eglantine: the floures come forth among the leaves, and at the top of the branches of a faire gold yellow colour: the thrums in the middle, are also yellow which being gone, there follow such knops or heads as the other Roses do beare."

The double form is also mentioned by Gerard, who speaks of it as "a prime rarietv about London, where it is kept in our chiefe gardens."

Parkinson in his *Paradisus* (1629, p 417) thus speaks of the single yellow Rose:—

"16. Rosa lutea simplex. The single yellow Rose. This single yellow Rose is planted rather for variety than any other good use. It often groweth to a good height, his stemme being great and wooddy, with few or no prickes upon the old wood, but with a number of small prickes like haires, thickeset, upon the younger branches, of a darke colour somewhat reddish, the barke of the young shootes being of a sad greene reddish colour: the leaves of this Rose bush are smaller, rounder pointed, of a paler greene colour yet finely snipt about the edges, and more in number, that is, seven or nine on a stalke or ribbe, than in any other kinde, except the double of the same kinde that followeth next the flower is a small single Rose, consisting of five leaves, not so large as the single Spanish Muske Rose, but somewhat bigger then the Eglantine or Sweete Briar Rose, of a fine pale yellow colour, without any great sent (sic.) at all while it is fresh, but a little more, yet small and weake when it is dryed."

The same author in his *Theatrum*, published in 1640, speaks of the vermillon Rose of Austria, or Rosa sylvestris Austriaca, quoting, no doubt, from his Flemish predecessors.

Then we come to Philip Miller, who, in the eighth edition of his *Gardener's Dictionary*, speaks thus of the Austrian Rose. We quote the eighth edition as being the one in which the Linnean nomenclature for plants in general was first adopted, but, no doubt, the details relating to this species were also printed in the earlier editions. It will be observed that the plant he describes is the one with copper-coloured flowers, which he differentiates from the "single yellow Rose":—

"The twelfth sort is commonly called the Austrian Rose. The stalks, branches, and leaves are like those of the last [the single yellow variety], but the leaves are rounder; the flowers are larger; the petals have deep indentures at their points; they are of a bright yellow within, and of a purplish copper colour on the outside; they are single, have no scent, and soon fall away. There is frequently a variety of this with yellow flowers upon one branch, and copper colour upon another. This sort of Rose loves an open free air and a northern aspect."

This yellow Rose has also been confounded with R. sulphurea and was by others considered to be a yellow form of R. gallica, but both these suggestions may, we think, in the face of the evidence here summarised, be dismissed as untrustworthy. *M.T.M.*

CELMISIAS.

THE Celmisias constitute a very charming genus of New Zealand plants, known in their own country as the Mountain or Horse Daisy—why horse, I wonder? They do not seem to be as well known in this country as their beauty and good habit of growth would lead one to expect; for to a very handsome blossom they add the attraction of foliage which is always decorative, and at its best period very handsome.

Their stiff, compact leaves, with matted, flannel-like lining on the undersides, are often covered on the upper side with silky hairs lying pressed down on the leaf, giving a silvery appearance to the whole plant.

After they are once established their culture appears to be quite simple. We grow them in sunny places in the valley, raised a little by preference, and with ample drainage; and though generally giving them a special mixture of soil which contains always a good deal of leaf mould, a rather better mixing than usual of our own very sandy soil, and some sharp river sand added, we have some plants growing quite contentedly in the ordinary rockery soil, which has had lime freely mixed with it. So that though lime is not indicated, they do not seem to be hostile to it. We grow them entirely without protection, and some of our plants have passed through four or five winters without suffering any apparent injury. Though they look a little sorry for themselves sometimes during the winter, they do not seem really to suffer, and they flower vigorously when June arrives.

When the plants have made good growth and developed a fair number of crowns they can be lifted in the autumn, and where a root or two can be secured with the offset, as is generally the case, they can be safely divided and replanted at once. They do not strike readily with us if without roots, under cold frame treatment.

If ripe and mature seed can be secured it germinates freely in about seven or eight months if sown in the autumn, or in about three or four weeks if sown in the spring under ordinary cold frame treatment, but as we find much, even of our own seed, is immature, it is worth while to go over it carefully, when it is easy to select plump, matured ones, if there are any, as it may be that in a whole seed-head there are none really likely to germinate. The dangerous time in the life of the seedling appears to be between the period when it has formed its second pair of leaves and its thorough establishment in its new quarters, whether it be thumb pot or box. Unless the water can is very carefully used the young plants seem liable to rot off at collar, and we have suffered some wholesale disasters at this period. We like to get them out as soon as we can into their permanent places, as the long roots of the young plants are easily broken, and seem to require greater freedom than they can have in a pot.

Generally speaking they may be said to want no coddling, but ask only for care in growth and plenty of sunshine and good drainage in after life. The species that have flowered here so far are C. spectabilis, C. coriacea (two forms, green leaved and silver leaved), and C. Monroi. We have had coriacea with flowers about 3 inches long. There are young plants coming along of six or seven other species, some of which should flower next year. *S. Marshall Bulley, Hants.*

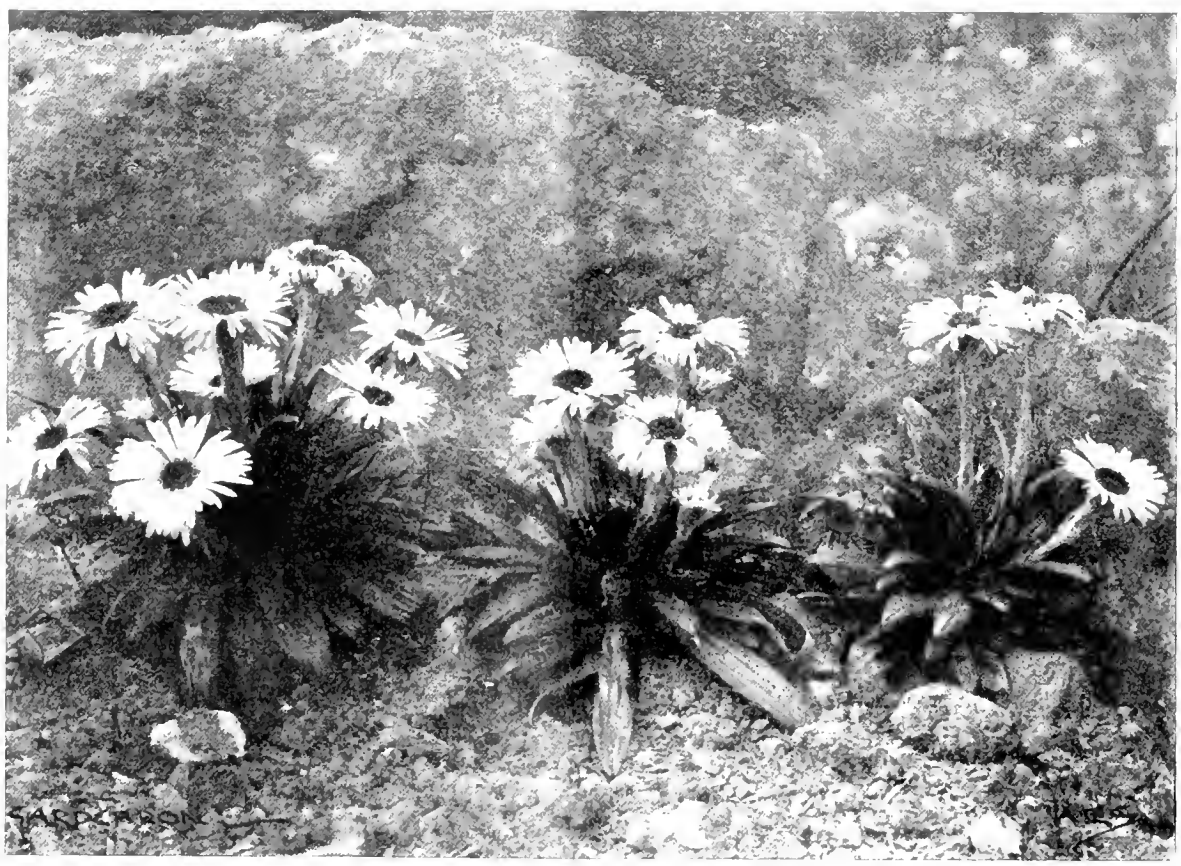

FIG. 1.—CELMISIA SPECTABILIS FLOWERING ON MR. BULLEY'S ROCKERY.

WATER GARDENS.

(Concluded from page 100.)

THE ROCK-POOL.

A FEATURE worthy of careful study in the formation of rock-pools is the advantage to be gained by excavating and preparing a much larger site than is actually required for the proposed area of water; not only does this admit of all the cement work being hidden, but excellent and ideal conditions are secured for the cultivation of marsh and bog plants without further trouble with regard to water supply. Presuming that a rock-pool 200 square feet in extent is proposed to be made, an area of 300 square feet should be excavated, and the bottom and sides securely cemented, as though 300 square feet of water surface were really required. Define the actual pool 200 square feet in extent, inside the basin, by placing large boulders that will serve to keep the soil back, and fill in the intervening space between the series of boulders and the cement sides with rubble to the extent of a few inches in thickness; then fill up with soil or peat, or both, according to the plant's requirements. A footway across this anywhere must be made with flat boulders resting on the cement bottom to form a series of closely laid stepping-stones broad enough to give a firm foothold, and they may be nearly or quite hidden with soil or shingle. A similar footway, if desired, can be made at the pool's margin. Thus planned the rock-pool will show no cement sides, the weakest part of the basin is secure against the action of the weather and against pressure, and a more natural-looking pool is the result, because one can plant around it many beautiful bog plants that make all the difference between a water garden and a hole with water in it. The water area need not be large, and if there is a large surface it may be covered with a number of the lesser Water Lilies to break up its area into smaller patches, and thus communicate to the rock-pool the ruling feature of the rock-garden—infinite variety.

Here, too, collections of plants are admissible without fear of a scrappy picture: of Nymphæas, a selection could be made of the white odorata, odorata minor, and pygmæa alba, small flowered, smaller flowered, smallest flowered respectively. Numerous pink and red Water Lilies of the Laydekeri group, such as lilacea, purpurata, and rosea prolifera; the pretty Nymphæa sanguinea, whose flowers are exceptionally dark red, whilst a good yellow will be found in odorata sulphurea or pygmæa Helvola, both gems that thrive well in the rock pool. Plant these in small baskets or in turf

mounds, as convenience may require. Rodgersias, Podophyllums, Meconopsis, many of the lesser Cypripediums, Trilliums, Orchis, Eomecon, a few of the lesser reeds and sedges, Galax, Shortia, Sanguinaria, Chamælirion, and the slender American Lilies will thrive apace in the wet soil around the pond and inside the cemented-containing basin, sites being raised up for those preferring drier conditions. In the water Frog Bit, Cabomba, Vallisneria, Limnanthemum, and Hottonia can be grown, whilst Azollas might have a little pool in the bog-bed, from which they could not escape. Sagittaria gracilis will represent the Arrow Heads. Skirting the pond may be placed patches of Primula rosea, P. sikkimensis, and some of the best forms of P. japonica, such as alba, sanguinea and splendens, with Gentiana septemfida, Iris cristata and verna among them.

of water that have served their purpose for a season or for all time. One can grow a few patches of Water Lilies in any moat, and many curling ponds I have seen in Scotland would certainly become more ornamental in summer if a few groups of Water Lilies adorned their generally uninteresting surfaces. They could be grown in baskets, and would not in the least degree interfere with the enjoyment of the "Roaring Game" in winter when they were resting quietly.

The ornamental basin or fountain is the greatest puzzle of all to plant. Such erections require but the slightest touch to do all that is required, and three or four small growing Water Lilies growing in open pans of Japanese or other ware to correspond with the materials of the fountain will prove that touch. If there is a jet of spray plant in that; if the water trickles and arrange the tubs in any way you choose, either in straight lines alongside a pathway, or, if the slope is limited, and places are required for a number of tubs, arrange them in the form of the letter S to get the maximum benefit of the fall of water on such a limited slope. Sink the tubs into the ground for half their depth, and convey with small iron water-piping the overflow of the uppermost tub to the next, and so on; fill each tub with good soil up to the ground level and with water up to the brim; plant from one to three Water Lilies in each, according to their strength; three plants of any of the pygmæa group will be readily accommodated in one tub, but one only of the odorata and Laydekeri groups will suffice. Plants may now be disposed around the tubs in the form of an attenuated but informal bed, choosing for the purpose any of the lesser Spiræas, the choicer forms of British Ferns, Astrantias, Miscanthus, Phormiums, Phlox, Irises of the Germanica and beardless groups, and any other plants whose flowers and foliage communicate an impression of waterside vegetation. Hide the tubs as much as is possible, but do not densely shade them, or the Water Lilies will find the water too cool for their well-being. There are scores of ways of using half-buried tubs effectually without the tub itself being such a dominant feature as now so often obtains, and many a novel method can be designed on the spot of so arranging tubs and plants that the latter appear to have possession of the site. One cannot expect an ideal water garden from the use of tubs, but a lot of very interesting plants can be well grown in them, and the plot containing them can be made as picturesque as one could wish.

George Bacon Mallett, Colchester.

FIG. 2.—CELMISIA CORIACEA, FLOWERING AT GLASNEVIN, IRELAND.

(For text see page 2.)

The rock-pool has this great advantage that will appeal to many—it enables one to grow a large collection of small plants without fear of spoiling its effect. As the rock-garden is the recognised home of the miniature representatives of the Alpine Flora, so may the rock-pool be regarded as the home of the miniature subjects in the water-loving flora.

THE MOAT, THE CURLING POND, AND THE ORNAMENTAL BASIN.

The more formal the environment of the water garden becomes the fewer are the opportunities offered to the planter for the formation of a realistic water scene of real merit. The margins of both the moat and curling pond are not generally fitted for a successful planting of waterside vegetation, but one can generally do something to alter the aspect of the dull stretches slowly so that the temperature of the water in the basin is normal, such Nymphæas as pygmæa Helvola, pygmæa alba, Laydekeri lilacea, and chrysantha may be grown in it quite well. If a persistent display of flowers is desired, grow a few additional plants in a reserve tank to replenish the fountain as occasion requires. Leave quite two-thirds of the water's surface unplanted; a lake, pool, or tank quite covered destroys the keynote of artistic water gardening.

TUB-GARDENING.

This method of growing water plants has not reached the highest limit of excellence possible for it. Although a series of tubs or half barrels are in no wise ornamental, it is not difficult to make them so, or to hide them altogether. Choose, if possible, a slope facing south for a site, provide a small supply of water at the top,

NOTICES OF BOOKS.

A TEXT BOOK OF BOTANY.

THIS is a small treatise prepared by M. Yates, and published by Whittaker and Co. It is intended for the use of students preparing for the Civil Service, London University, Cambridge Local, Oxford Local, College of Preceptors, and South Kensington examinations. The plan of the work comprises the explanation of the principal technical terms in common use. Thus we are told that a "runner" is an underground stem, and as an illustration the Strawberry is cited and even figured, but we think the youngest boy in the garden would know that the Strawberry runner is produced above ground. We doubt also whether the examiners would look kindly on such a definition as this:—"A seed is a body produced by the agency of a flower within the ovary or seed-box. L. *ovum* an egg." If this means that the ovary is synonymous with the ovum, or egg, we fear the examiners would frown, and certainly that would pronounce the definition as inadequate.

The definition of an "inferior ovary" as growing "from below the calyx" is more specious than real, and the word "axillary," as used instead of axile in describing one mode of placentation, conveys a quite erroneous impression. The explanation of fertilisation as the "process by which the pollen-cells are conveyed into the ovary, so as to enable it (the ovary) to produce the seeds," is scarcely more accurate. Misprints will, of course, intrude themselves in such a book, but they are in this case rather numerous, and sometimes embarrassing, as when we read of an "Eteris" of achenes in the Buttercup. Instructions are given as to the method of describing plants, and over 200 questions are added, taken from the papers set at various examinations. Had the author studied some of these questions carefully he (or, query, she) would have avoided some of the doubtful statements to which we have alluded. The book is copiously illustrated, and has an index.

CANN HOUSE.

(See Supplementary Illustration.)

CANN HOUSE, the residence of Mr. H. Grigg, is distant about five miles from Plymouth, and is situated in close proximity to one of the creeks of the River Tamar. The ground slopes steeply down from the house to a long and winding dell or coombe, along which, at the lowest level, meanders a clear stream. The surroundings of this stream, by the side of which runs a path, are for a long distance tastefully planted with trailers, dwarf shrubs, moisture-loving plants, and alpines between the rocks on the higher levels of the banks. The grounds are excellently laid out and planted, and an object-lesson is afforded of the fine effect produced by grouping the same species together rather than dotting single plants of various species indiscriminately about, a practice too often followed in gardens. A large and representative collection of plants is grown, and on the higher ground many tender subjects do well, though in the lower levels by the stream-side, sharp frosts are often experienced.

Among the dwarfer plants doing well in the neighbourhood of the stream, where the rock-formed banks afford ideal sites for their culture, both in the sunshine and shade, were Ourisia coccinea, occupying a large space, Ramondia pyrenaica, and its white variety, R. serbica, Haberlea rhodopensis, Dryas octopetala, and D. Drummondi, Androsace lanuginosa, A. sarmentosa, A. Chumbyi, Anemone Pulsatilla in a dry spot; A. sulphurea in a damp one; A. Robinsoniana, covering a flat space about 7 feet across and in full bloom at the time of my visit in April, was a beautiful sight; I noticed also Primula megaseæfolia, P. marginata, P. viscosa, P. Sieboldi, out all the winter; with P. rosea and P. japonica margining ornamental water, in which the best of Marliac's Water Lilies are grown. Gentiana acaulis, G. verna, G. asclepiadea, and its white form, Podophyllum Emodi, and Galax aphylla were in the best of health. Among other plants may be mentioned Crinum turricum, and the rarer O. stellatum, Lithospermum prostratum covering the rocks with foliage and opening buds, Saxifraga longifolia, S. Gresebachi and others; Erythroniums in variety, Nierembergia rivularis, evidently happy, Iris juncea, I. tuberosa, and a large colony of I. lævigata occupying a level site higher up the stream; Tigridias, the Prophet Flower, Arnebia echioides, Dabeocia polifolia, and its white variety, Genm reptans; Edrianthus (Wahlenbergia) pumilorum, Fritillaria aurea, F. verticillata and others, Vaccinium, Vitis-Idæa, and Bryanthus empetrifolius. Tropæolum speciosum (the Flame Nasturtium), and T. polyphyllum rambled over the rocks at will. Shortia galacifolia was represented by twelve large plants, which were in full flower at the date of my visit, in one group in a sheltered and shady nook. In a damp spot and in partial shade, Meconopsis Wallichi grows to a height of 8 feet, and Astilbe Davidi lasts long in flower, while by the side of the stream are large colonies of Lomaria procera, the Ostrich Fern, Struthiopteris (Onoclea) germanica, Solomon's Seal, Saxifraga peltata, and Adiantum pedatum. Amongst other plants in the neighbourhood of the stream are Senecio chrysorum, with self-sown seedlings springing up around it; S. tanguticus, rapidly annexing a large space of ground; Mohopospermum cicutarium, Ligularia macrophylla, Phormium tenax, and its variegated form, as well as P. t. purpureum, P. t. macrophyllum, P. t. pendulum, and P. alpinum, while in an open spot Gunnera manicata spreads its enormous leaves, and hard by the tiny little G. magellanica shows its small, rounded foliage. A pleasing effect is obtained by the introduction of dwarf shrubs into the stream banks and the surrounding ground. Philesia buxifolia was the picture of health, and produces its Lapageria-like blooms in quantity; Daphne cneorum, often difficult to grow, was obviously at home, as was the pink New Zealand Broom, Notospartium Carmichaeliæ, Gaultheria procumbens, G. nummularifolia, and G. trichophylla spread over the rocks; dwarf Acers brighten the surroundings in summer and autumn with their richly-coloured leaves, while Azalea Anthony Koster and A. rosea flore pleno are charming in the late spring. Other shrubs include Cistus corbarensis, Corylopsis spicata, Grevillea rosmarinifolia, and G. sulphurea, Genista Ardoini, Pyrus nivalis, Spiræa gigantea, S. Lindleyana, and S. ariæfolia. A fine specimen of the Fan Palm (Trachycarpus excelsa) gives a tropical aspect to the spot, and there is a good example of Cupressus Lawsoniana Triomphe de Boskoop. Leaving the precincts of the stream for the higher ground, a fine mass of Erica carnea is passed, and the Pernettyas hard by berry well. In the other portions of the grounds a large collection of interesting shrubs, trees, and plants is grown. Amongst the shrubs I noticed Abutilon vitifolium, both the type and the white-flowered variety, Amelanchier canadensis, and A. Botryapium, which, though held to be synonymous, differ in foliage and flower, Arbutus canariensis, Azalea indica, and among the Berberis family a large group of B. stenophylla—a gorgeous sight when in full bloom, Buddleia Colvilei, which has flowered, Cæsalpinia japonica, and the rare C. (Poinciana) Gilliesi, which is 6 feet in height against a wall, Calycanthus macrophyllus, Carpenteria californica (see figs. 4 and 5), much healthier than is usually the case, Caryopteris Mastacanthus, Cistus ladaniferus, rare in gardens, Citrus trifoliata, 12 feet in height, which invariably flowers freely and also fruits; Clethra canescens, Cornus florida, C. Mas variegata, 10 feet in height and as much through, Corylopsis pauciflora, a large group of the new Cotoneaster angustifolia, Cytisus capitatus, C. nigricans, Daphniphyllum glaucescens, Disanthus cercidifolius, whose foliage turns a brilliant scarlet in the autumn, Distylium racemosum, Dremys aromatica, and the far more beautiful D. Winteri, Edwardsia (Sophora) grandiflora, and E. microphylla, both of which flower well; the gorgeous Embothrium coccineum, many Escallonias, among which were remarked E. Langleyensis ×, the Lovely Eucryphia pinnatifolia, and the scarcer E. cordifolia, Exochorda grandiflora, Fabiana imbricata, Fuchsia sellowiana, Genista tinctoria flore pleno, G. viminalis; the Snowdrop Tree (Halesia tetraptera), Hamamelis Zuccariniana, and the new H. mollis, Hydrangea quercifolia, Illicium religiosum, a pretty white-flowered shrub seldom met with, Lagerstroemia indica, another rarity, Ledum latifolium, Leptospermum lanigerum, Ligustrum coriaceum, groups of the best Lilacs, Loiseleuria procumbens, Loquat (Photinia japonica), Magnolia conspicua, M. stellata, M. Soulangeana, M. fuscata, Medicago arborea, Nandina domestica, Olearia Haastii, O. macrodonta, O. nummularifolia, very rarely grown, Olea fragrans, Osmanthus rotundifolius, Ozothamnus rosmarinifolius, Piptanthus nepalensis, Pittosporum Ralphii, and others; Pyrus Maulei grandiflora, P. Malus floribunda, and its variety atrosanguinea; many members of the Prunus family, including P. pendula, P. sinensis, P. Watereri, P. triloba, P. Davidiana alba and rubra, Rhapidolepis ovata, Rhododendrons, amongst which were R. Hodgsoni and R. racemosum, Rhus Cotinus purpureus, Ribes speciosum, Robinia hispida, Rubus deliciosus, Salvia coccinea, Senecio Greyi, Skimmia japonica, Solanum crispum, Spiræas in variety, Stuartia pentagyna, S. virginica, Styrax Obassia, Tamarix odessana, and T. Pallasi rosea, better known as T. hispida æstivalis, of which there was a large group of thirty plants that must afford a charming picture when their pink flower-plumes and feathery foliage are at their best; Tricuspidaria lanceolata, better known as Crinodendron Hookerianum, covered with bud, Veronica Hulkeana, Viburnum plicatum, V. macrocephalum, and Xanthoceras sorbifolia.

Of trees, the most noteworthy were Acacia dealbata; the Judas Tree, Cersis siliquastrum, Cornus capitata, better known as Benthamia fragifera, the new Davidia involucrata, the Honey Locust (Gleditschia triacanthos), the Kentucky Coffee Tree (Gymnocladus canadensis), Ilex latifolium, T. Taraio, Koelreuteria paniculata, and Parrotia persica, both very brilliant in their autumnal colouring, and Paulownia imperialis. Of climbers there were present Akebia quinata, Berberidopsis corallina, and Lapagerias, rose and white, with Tropæolum speciosum, all luxuriating on a shady wall, in front of which the Mocassin Flower (Cypripedium spectabile) grows with astonishing vigour; Clematis balearica and C. cirrosa climbing trees, C. montana rubra, newly introduced, Ercilla (Bridgesia) spicata, Hydrangea scandens, which had ascended the trunk of a giant Cupressus macrocarpa to a height of over 20 feet; Jasminum primulinum, Mandevilla suaveolens, Sollya heterophylla, Trachelospermum jasminoides, and T. japonicum maculatum.

In front of a sheltered south wall were growing some of the rarest and tenderest subjects, including Abelia floribunda, Agapetes buxifolia, Correa cardinalis, Crossosoma californica, Desfontainea Hookeri, Diosma gracilis, Eriostemon neriifolius, Libonia floribunda, Mitraria coccinea, and Olearia nitida. In the same border were a number of Irises, amongst which were I. gracilipes, I. cristata, I. fimbriata, flowering, I. Willmottiana, I. Warleyensis, I. bucharica, I. Douglasiana, I. bracteata, I. Purdyi, I. tenax major, and I. Oncocyclus hybrids as well as Calochorti, Gerbera Jamesoni, Tecophilea cyanocrocus, Gladiolus tristis, Ixiolirion Pallasi, Tulipa Greigi, and many rare bulbs. Amongst other plants grown were Calceolaria violacea, Convolvulus cneorum, Dendromecon rigidum, Desmodium pendulifolium, Hedychium Gardnerianum, which never fails to flower well every autumn; Ostrowskia magnifica, of which there are two fine groups in robust health, Phyteuma comosum, Rehmannia angulata, the beautiful Californian bush Poppy (Romneya Coulteri), and a colony of Watsonia Ardernei, which threw up twelve flower-spikes last year. Against the house were growing Azara microphylla, Ceanothus divaricatus, and C. Gloire de Versailles, Cassia corymbosa, Clematis indivisa lobata, M. gigantea, M. grandiflora, Roses and other plants. The glasshouses contained a select collection of subjects, one of the most noteworthy of which was a splendid specimen of Solanum Wendlandi. *S. W. Fitzherbert.*

(Concluded from page 408.)

THE BOROUGH.

SITUATED on the Surrey side of London Bridge, close to St. Saviour's Cathedral, this is one of the most cramped and inconvenient of all the London markets, yet the business transacted there is, of its kind, probably unsurpassed. For many years it has been as noted for its Potato trade as a neighbouring portion of the Borough High Street is for the Hop trade, and some millions of tons of the homely tuber have been sold in its limited area since I first became acquainted with the market. But, though Potatos are a great feature, other vegetables are also sold on an extensive scale, and fruits are dealt with largely, especially imported fruits, which are so popular with the masses, such as Bananas and Oranges. For South-Eastern London this market is very convenient as regards distance, and it is regrettable that it cannot be rendered more commodious and supplied with better approaches. The Borough Market Trust, in whom the management is vested, have effected several improvements, and the salesmen enjoy some advantages now which were foreign to them years ago. For instance, one part is well covered and lighted; but the whole

place is so restricted, and has such a mixed, confused appearance, that it will need a substantial advance in many directions before it can be regarded as a credit to a city like Southwark.

BRENTFORD.

Incidental mention was made of the Kew Bridge Market in the opening remarks of these articles; it only remains to add here that since these notes appeared the new market has been completed and opened. In many respects it is the best-designed and most spacious in the metropolitan district. Beyond this, from the way the trade is developing, it bids fair to rival in a few years some of the largest in the amount of business transacted. It can never be expected to equal Covent Garden for first-quality produce of any kind, but as it is so convenient for the West of London shopkeepers and providers, it is probable that high-class fruit and vegetables will in time have an important place in the market. At present good average fruit, vegetables, flowers, and plants, with imported fruits, hold the principal part of the trade. Immediately adjoining the London and South-Western and North-London stations, communication is readily established with the London and North-Western Railway, so that a wide area of the country can be tapped for supplies, as well as those which come by road from Western Middlesex and Surrey. The Brentford District Council is not likely to do a better service to their locality than has been rendered by the establishment of this handsome market.

LOCAL MARKETS.

Beyond the depôts at St. Pancras and King's Cross, chiefly for Potatos and other vegetables, there is little other market accommodation in the metropolis, with all its millions to be supplied. At the fruit enquiry instituted by the Board of Agriculture in 1904 some difference of opinion was expressed as to the desirability of increasing the number of markets. Mr. Wm Poupart, of Twickenham, and Mr. E. Rochford, of Cheshunt—both weighty witnesses—were not in favour of such an extension, but appeared to think that concentration in a few centres was preferable for growers and buyers. On the other hand, Mr. W. J. Lobjoit, of Heston, and Mr. W Sams, of Worthing, were of the opinion that we cannot have too many markets." Even Mr. G. Monro favoured this view to some extent, for he said: "It is much better for a man with a small lot of goods to sell it in the locality in a local market than to go to the expense of a long journey, with commission for the sale of the fruit, and possibly it is not worth the salesman's while. These small consignments give a great deal of trouble."

But there is another aspect—namely, the benefit to the retailers and the public which arises from facilitating the progress of the goods from producer to consumer. Mr. Lobjoit touched upon this when he said: "If a municipal market could be opened in the south of London somewhere about Balham it would be a very great advantage, both to the people who live there as well as to the growers who send there. Does it not seem absurd that cartloads of fruit should be drawn past the shops up to Covent Garden, and then have to be taken back again to Balham?" It is difficult to conceive how two opinions can exist on this matter; the waste of time, the expense incurred, the risk to the produce are all opposed to the interests of grower, retailer, and consumer. Yet it is not only in South London, but in other districts of the metropolis, where the same anomalous state of affairs prevails. The large central markets have their special uses, and are indispensable; but when an assemblage of human beings reaches the magnitude that London has attained, judiciously-placed local markets, as concerning the food of the people, are quite as much a necessity as the means of locomotion upon which such huge sums are expended. *Lewis Castle.*

MOVING LARGE TREES.

THE Chestnut tree (see fig. 3) has had an uncommon experience, over and above that of being successfully transplanted after having attained the age of some 30 years. It was not decided until the last minute that this tree should be transplanted, and therefore it did not receive the preparation that was given to some other 32 specimens in the shape of root-pruning some months beforehand to cause the roots to throw out young fibres and make a compact ball close to the bole of the tree. Bearing this fact in mind I had a much larger circular trench dug out than usual, working well under the roots, and, after carefully wrapping round with mats the ball of earth thus made, the tree was ready for shifting.

The question was how? There it stood, weighing about four tons, too large for my tree shifting trolley, guarded in front by some three or four yards of newly made ground and a trench 4 feet wide and 3 feet deep.

It had to be moved, and we decided to pull it over into a horizontal position after fixing some strong chains round the ball, the chains being prevented from cutting in too deeply by placing pieces of wood at short intervals between the mats and the chains. The tree was then lifted out of its hole by means of an endless chain, lowered on to a platform arranged on rollers, rolled on to firm ground by manual labour and again lifted by the chain gear on to a stone trolley and wedged up to prevent its rolling off. After arranging several men to steady the top, it was drawn to its destination, some 600 yards distant, accompanied by the wondering gaze of some and the cynical smile of others.

Yet there it stands to-day in full leaf, a living testimony to the fact that although always desirable it is not absolutely necessary to prepare large trees twelve months before transplanting. In moving 33 large trees there are many incidents of an amusing and an annoying character, such as the giving way of a part of a brick drain picked up in one of the balls, an axle breaking, &c., but nothing of great interest to the readers of this journal. *John Kinmont, Westgate-on-Sea.*

FIG. 3.—CHESTNUT TREE 30 YEARS OLD MOVED WITHOUT PREVIOUS ROOT-PRUNING.

THE PROPAGATOR.

ROSES.

WHEN the shoots of Noisette, China (monthly), Roses, the earliest and the latest to bloom, Tea, and the so-called Tea hybrids, have become fairly firm in consistency, propagation by means of cuttings, furnished with a base of the older wood, may be undertaken on mild hotbeds made up of tree leaves and a small quantity of stable litter, and covered with an ordinary garden frame. Some gardeners prefer to place the hotbed on the north side of a wall, and to do so is certainly a saving of labour in the matter of shading, but in no other way.

If many cuttings are to be made, the hotbed, when it has reached its greatest degree of heat, should be made level and firm, and receive a 4-inch thick layer of leaf mould, into which the Rose roots will enter almost as soon as they form, deriving nutriment and moisture therefrom; otherwise they are apt to turn black and die. Over the leaf mould a layer of sandy loam should be laid to the depth of 4 inches, made firm, smooth and level. When the heat has declined to 75° Fahr. the cuttings may be made and inserted in rows, and barely touching each other.

In making them, remove the unripe tip, and the leaves so far as the cuttings enter the soil, and the end leaflet on each. As has been stated, each cutting should be provided with a "heel." A light having been filled with cuttings, the bed of soil should receive a thorough application of water (warm preferably), and the light should be put on, with a mat over all, if the sun be shining strongly. When the frame is filled with the cuttings, it should be shaded only when the sun is upon it, and kept close, except for the space of half an hour between 8 and 9 a.m., when the lights should be drawn off in order to dissipate moisture. When it is noticed that the cuttings generally have become callused, the amount of shading may be lessened, and the frame kept open for an hour, until, as roots form on the cuttings, more and more air may be admitted, and the shading dispensed with. In a month the

operation will be completed, and the little plants may then be fully exposed. The plants may remain in the frames till the spring, treating them as hardily as may be desirable.

If the cuttings are inserted singly in small sixties (3-inch pots), the routine is almost the same, excepting that spent Mushroom bed dung or coarse leafmould may be put over the one crock at the bottom of the pot.

The rose shoots, before being made, should be kept from flagging by immersing them in a large watering-can having a small quantity of water in it—no time being lost in putting them into the cutting frame after they are prepared.

LAURUS CAMPHORA.

IN this month cuttings may be inserted of Laurus Camphora, in pots or pans, filled with hard peat, such as is used for Ericas, and surfaced with about an inch layer of washed sand. Choose cuttings of this year's shoots, strong and well developed, with plenty of leaves and strong buds, taking them from the upper side shoots, and every leaf should be preserved, even those close to the base. Insert the cuttings 1 inch deep in the sand, so that the bases just touch the soil. Apply water, cover the pans or pots with bell glasses, and afford a bottom heat of 76°-86°, with regular application of water and the necessary shading. In about five weeks the uppermost buds will have unfolded, a sign that roots have formed, when air may be afforded, and a week later the plants may be potted, an operation requiring great care owing to the stiffness and inelasticity of the roots.

MISCELLANEOUS.

JUNE and July are good months for the budding of variegated Hollies, and the male Aucubas on plants of the female variety, for striking cuttings of Eupatoriums on mild bottom heat, and propagating from the old leaves Rex and other leaf Begonias, and Gloxinias under bell glasses, without bottom heat.

The following species of shrubs and trees may be layered in the next two months:—Amorpha, Azalea, Berberis, Bignonia, Calycanthus Ceanothus, Cercis, Clematis, Cornus, Cotoneaster, Deutzia, Euonymus, Œsculus macrostachya, Laurus, Magnolia, Ornus, Pæonia, Rhamnus, Rhododendron, Rhus Cotinus and others, Ribes on the soil, Rubus (the points of shoots), Spiræa lævigata, which grows with difficulty from cuttings, and Viburnums, which do not strike from cuttings. *F. M.*

CARPENTERIA CALIFORNICA.

ALTHOUGH introduced from the Sierra Nevada in 1880, this summer-flowering, somewhat tender shrub is still not in general cultivation.

It belongs to the Nat. Order Saxifragaceæ, and makes a nice bush when planted in a sheltered but sunny position out of doors. The flowers are produced in clusters at the termination of the branches; they are white, about 2 inches in diameter, and in general appearance are not unlike those of a Cistus. The leaves are broadly lanceolate and entire, from 2 to 3 inches long, with a whitish minute pubescence on the under surface. It is figured in the *Botanical Magazine*, t. 6911.

The plant represented by the photograph (see fig. 4) has been in its present position in the Cambridge Botanic Gardens for some years, and is now a fine bush 4 feet in height and as much through, and produces a good display of flowers every summer. *E. J. Allard.*

VEGETABLES.

WAX PODDED AND BUTTER BEANS.

IT was a good thought of Mr. Gibson's to draw attention in his *Kitchen Garden Calendar*, in the issue of June 9, to these Beans, comparatively unknown to gardeners and their employers in our country. There is, as I am aware, an unreasonable prejudice on the part of some on account of the colour—a pale yellow; but in view of these Beans being of an agreeable flavour, and very tender when cooked, and in some varieties destitute of parchment, and abundant bearers, this objection ought not to stand in the way of their use for the best table. Indeed, we ought to welcome so nice a vegetable which adds variety to the dinner table. There are climbing varieties of Butter Beans, which, like Scarlet Runners, need support for the bine; and dwarf growing varieties such as the Sugar Bean mentioned by Mr Gibson. The seeds of these beans are, like the pods, of a light yellow or creamy colour, and when ripe they may be employed similarly to the Haricots of the shops. All the varieties need a warm site and to be sown not earlier than the last week of April, and then onwards to the end of the month of June or the middle of July, according to the climate of the district. A south border affords the best position for the earliest and the latest sowings. These beans are usually served in Continental households with melted butter, the one British sauce, as our foreign friends believe, or with a slightly acid one. As for example the so-called *einbrenn* of the German cookery-books, which is compounded of a little shredded onion cooked in a small quantity of butter to a light brown colour in a stewpan, to which some good soup is added, and finally a table-spoonful or lesser quantity of vinegar or lemon juice, and the beans, strained from the water in which they were cooked, stirred into the sauce and warmed up—not boiled.

Plain boiled Butter Beans form an excellent addition, when allowed to get quite cold, to mixed salads. In preparing the pods for the table it is not considered necessary to shred them according to English methods, and thus boil out their flavour, but simply to break each pod into two or three pieces after removing the stalk and tip. If a Bean does not snap easily across it is too old and must be cast aside. The protuberance of the seeds in the pods is not a certain sign of unfitness for the table, as would be the case with green French Beans. *F. M.*

SPRING CABBAGES.

I HAVE seen from week to week in the *Gardeners' Chronicle* notes respecting the qualities of the varieties, Ellam's Dwarf and Flower of Spring. Ellam's Dwarf is very valuable here, being of good flavour, very early, and very few bolt to seed. It is exactly what one requires in a spring Cabbage. "Flower of Spring" requires much more time to come to maturity and it is given to "bolting." I prefer Sutton's Favourite to Flower of Spring. *F. W. Pratt, King's Court, Chandlersford, Hants.*

HAVING followed with interest the opinions of various correspondents in the *Gardeners' Chronicle* upon the merits of different varieties of Cabbage for early supply, I should like to say that my experience of Ellam's Early Dwarf does not coincide with that of the two writers in a recent issue. Here, it has always shown a tendency to "bolt." Flower of Spring has proved itself superior in this respect. Some four or five years ago I made a trial of ten sorts, each variety being respectively "the earliest and most desirable variety in cultivation." The result was, in racing parlance, an easy first for a variety supplied by the Messrs. Dicksons, of

Fig. 5.—A spray of Carpenteria californica; flowers white, fragrant.

(For text see page 6)

Chester—named by them "First and Best," a name that I have since found to be well bestowed, and one that the variety has worthily upheld with me. This variety is now my mainstay for a first early; it is of dwarf habit, good flavour, and fair size, combined with very few outer waste leaves; and, what is more to the point under discussion, a non-bolter. It is, in my opinion, far superior to Ellam's in every way. "First and Best," with "Flower of Spring" and Webb's Emperor for succession, form a trio that is, to my mind, very hard to beat. *H.B.J., Birchley Park, Kent.*

EXHIBITING VEGETABLES.

I NOTE the remarks of "A.D." and of Mr. Pritchard anent the above subject in a recent issue; but their comments do not alter the fact that Parsley *is* shown in pots in Scotland as a vegetable. I admit no wise judge would disqualify in the circumstances I referred to, where six sorts of vegetables were shown with Parsley as a foundation, but all judges are not wise—as we know from experience. In the circle in which "A.D." moves and judges, I quite understand that Parsley is used as a groundwork for vegetable collections, but what would "A.D." and "Mr. P." do if they were called upon to judge a collection consisting of Cauliflower, Leeks, Onions, Turnips, Potatos, and a beautiful plant of Parsley in a pot, as we see at Scotch shows, staged as six varieties of vegetables? When I learn that Selaginella is a table plant, I will consider Mr. Pritchard's references *apropos*. *J. A. Simpson, care of Dobbie & Co., Rothesay.*

SHALLOTS

WHERE large quantities of this useful member of the Onion tribe are required, it is well to follow the practice of the market growers in the Channel Islands and sow the seeds of the plant instead of planting the bulbs in early spring, the produce being much finer as regards size. Those who may elect to do this should leave bulbs from the early planting, when they will flower in good time for maturing their seed by the end of September or earlier according to climate. The seeds can be stored till March and sown at the same time as the main crop of Onions, and in the same manner as regards depth of drill, firming the soil, and rolling it after the sowing is made. New seed should not be sown thickly, and in no case should the seedlings be allowed to remain nearer together than 6 inches in the rows, the latter being 9 inches apart. Seedling Shallots have been grown to a weight of 4½ ounces, but a lesser weight is usually the most useful and economical in cookery. *F. M.*

The Week's Work.

THE KITCHEN GARDEN.

By J. GIBSON, Gardener to His Grace the Duke of PORTLAND, Welbeck Abbey, Notts.

Spring Cabbages.—About the 20th of this month is an excellent time to make the first sowing of this vegetable, to be followed by a later sowing a fortnight afterwards. The provision of a good seed bed is essential, for in dry seasons there is often a difficulty in getting the seeds to germinate strongly and evenly. If the weather is very dry it is advisable to soak the ground a few days prior to sowing rather than damp the soil after the sowing has been made, which would tend to cake the surface. Sow thinly and prick the seedlings off at 3 or 4 inches apart into rich soil. The growth will be somewhat retarded by this process, but it will result in a gain in the end. In light soils and where the rooting medium is suitable pricking out is less essential than where the soil is of a heavy nature. Sow the variety which suits the locality best. I cannot recommend a more suitable one than Flower of Spring, which seems to be successful everywhere.

Shallots.—The earliest bulbs of these will soon be ripening, and as soon as growth is completed lift and dry them carefully in readiness for storing later on. It is usual to dry these in the sun directly after they are lifted, but I think they are not so likely to lose weight if dried in the shade. When they have been cleaned for storing they will be in a better condition for full exposure to the influences of wind and sun.

Carrots.—Green-fly has been troublesome on Carrot-tops in many places. If the foliage suddenly droops down, you may be sure it is attacked by fly, but being of the same shade of colour as that of the foliage the pest is not readily detected until the damage is done. It appears to be a very small species of green-fly that is troublesome here. Syringe the plants with soft-soap and water or diluted quassia water, which if applied once or twice each week will keep the pests at bay.

Cauliflowers.—These will be rapidly "turning in," and a strict watch should be kept daily on the crop that no loss may arise through the "heads" losing their purity of colour through exposure to the influence of the weather. Very often Cauliflowers are left growing until they are long past their best, and subsequently given away as surplus, but if they had been cut at the proper time they would have been much more appreciated and more useful. Draw soil to the stems of young plants in exposed places to prevent them being blown about by winds. Amongst the best varieties tried here have been Dean's Early Snowball and Sutton's Magnum Bonum, and, whether grown in frames or in the open, they are of the best for early supply. There is still time to plant for succession. Plantations made now should come in at the end of the season and just in front of the early Broccolis.

Mushrooms.—At this season it is advisable to spawn a piece of meadow-land if Mushrooms are generally scarce in the fields in autumn. Unless spawn is in the ground no Mushrooms can be expected. Place pieces just under the turf 2 inches deep and a yard apart. With suitable weather conditions and soil, a crop may reasonably be expected later on; in any case, the method is well worth a trial.

THE HARDY FRUIT GARDEN.

By W. A. COOK, Gardener to Sir EDMUND G. LODER, Bart., Leonardslee, Sussex.

Apricots.—These fruits are now swelling rapidly. Prune back outward-growing laterals, and nail in the shoots needed for extension. It is well also to tie in a few clean, healthy branches about the middle of the tree. Keep a sharp look-out for such insects as earwigs and woodlice, but if the walls and the trees are frequently syringed, and providing they have been attended to as advised, very few lodgings will be available for such pests. See that the roots are well supplied with water, and apply another mulching, for by this means the ground is kept from cracking. Borders under south and south-west walls become very hot and dry, and our borders situated in that aspect recently registered as much as 95° on the ground and 136° on the wall itself, the figures being taken at 3 p.m. Continue to syringe the foliage till the fruits begin to colour. Frogmore Early, as the name implies, is an early fruiting variety, and its fruits will soon begin to colour. They are small, but very useful, on account of their ripening early. The variety Large Early, ripening from the middle to the end of the present month, makes a good successor to Moor Park. Shipley's is a large cropper, the fruits being of a good size and splendid for bottling. Moor Park is a great bearer, and a general favourite. There are also several other kinds scarcely distinguishable from the last-named. The fruits should be gathered when ripe, and be laid on soft paper placed over a layer of wood wool.

Apples.—Early varieties of these fruits must not be allowed to suffer from want of water, or the fruits will not mature thoroughly, and early Apples are not of the best flavour unless thoroughly ripened. These apples very often ripen prematurely during a spell of hot, dry weather. Mr. Gladstone, Early Margaret, Early Harvest, and Irish Peach are the first kinds to ripen, and they are usually ready for gathering in July. Irish Peach, which, when well grown, is of excellent quality, is the latest, and to secure it at its best it should be thoroughly ripened on the tree and eaten immediately. It can be grown on cordon, bush, pyramid, and horizontally-trained trees. Remove all bad leaves from the trees by hand picking, or wash them off by heavy syringings. This procedure will also apply to all small fruit trees grown for special produce, for after the trees have had the points of the shoots taken out, or after they have been summer-pruned, a good washing cleanses the trees and frees them from all insects and small leaves which have been injured by aphis.

Raspberries.—These fruits will be ripening fast, and should have nets placed over them. See that this protection is sufficiently high, so that growth is not interfered with. If some T-shaped pieces of deal about 4 feet wide be nailed on to the wire supports the nets can be hung over these. Have the framework high enough to allow the top of the nets to be 7 or 8 feet from the ground, leaving a small opening, which should be tied with string, for entry. The fruits can then be gathered in a comfortable and business-like manner. The old system of nets simply flung on the canes does not protect much fruit, and the rods grow up through the meshes of the nets, allowing birds to settle and eat or damage all the best fruits. Raspberries are a heavy crop this year. Superlative, Hornet, Norwich Wonder, Baumforth's Seedling, and Fillbasket are among the best varieties.

Figs.—These trees are now making rapid growth, and should have their main branches secured to the wall. The tops of the growths should be taken out when sufficient wood has been made, as this will hasten the ripening of the fruits, and also assist the later growths at the base of the tree. See that trees in very dry positions are not suffering from lack of water. Disbud if too many growths are present, and pinch out the points of those that are growing too freely, or these will rob the weaker-growing ones. It is a good plan to place the fruits when ripening in small muslin bags, which, if tied fairly lightly about the stalks, will keep all insects away.

Peaches and Nectarines must be syringed and be well supplied with water. It is surprising what a large amount of moisture trees on a south wall require.

Fruit-room.—Keep this structure well ventilated and as cool as possible if fruit is still contained therein, but if all the fruit has been used, take the first opportunity to give the whole structure a thorough cleansing. Let the walls be limewashed, the wooden uprights and all the shelves scrubbed with hot water and soap. Every available crevice should be made thoroughly sweet and clean, so that it may be made wholesome for the reception of fruit. A good fruit-room should be spotlessly clean and free from all taint of mustiness.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower to Sir TREVOR LAWRENCE, Bart., Burford, Surrey.

Oncidium Claesii.—At Burford plants of the new and recently imported Oncidium Claesii are tied perpendicularly to strong teak stakes, the base of the stems being fixed firmly with crocks in pots of a suitable size, provided with a layer of peat and living sphagnum-moss over the drainage. The plants are staged at the coolest end of the Odontoglossum house, where they are syringed overhead several times a day. New growths are starting, and the plants appear to be responding well to the treatment afforded them. It is stated that this Oncidium belongs to the microchilum group, which includes such well-known species as O. macranthum, O. superbiens, O. serratum, &c., and the treatment generally afforded these plants should also prove suitable for O. Claesii.

Lælias.—Lælia anceps, L. albida, L. autumnalis, and L. Gouldiana are all making rapid growth, and they should therefore receive generous treatment. Afford each plant plenty of water whenever it is necessary. The structure in which they are growing should be freely ventilated during the warmest part of the day, and only a very thin shading will be necessary to protect the inmates from the full glare of the sun. The roof shadings should be removed early in the afternoon so that the sun may raise the temperature of the house to 90° or more. At the same time give the plants a good syringing overhead with clear water, and well damp the paths and parts beneath the staging, &c.; but on no account should the plants be syringed

on dull days, as the young growths sometimes rot through water lodging in them. When finishing preparations for the night, open the bottom ventilators, and those at the top a trifle, to allow any excess of moisture to escape. Allow the temperature of the structure to fall to 65° during the night time. Vanda teres will also thrive well in this house provided it be syringed thoroughly several times each day.

Plants of Miltonia Phalænopsis should be placed well up to the roof glass, under a shaded part if possible, but if this is not convenient, a sheet of tissue paper spread over them will answer the same purpose. Any plants of this Orchid that require more root room should be re-potted at once, as the young "breaks" are now pushing fresh roots. Afford plenty of drainage to the pots and use the ordinary Orchid compost as a potting medium, taking care to avoid over-potting. Give plenty of water at the roots until the new growths are completed.

Barkerias.—The pretty Barkeria spectabilis is now in bloom here in the Mexican house, where it is suspended close up to the roof glass, a position which suits this plant admirably. Such varieties as B. Lindleyana, B. cyclotella, B. Skinneri, and B. melanocaulon are also worthy of attention, the flowers lasting for a long time during autumn and winter. These plants are now commencing to grow, and should be re-potted. Turn them out of the old compost and thoroughly wash the stems and old roots with some safe insecticide. They should also be thoroughly examined for mealy bug, which, if not eradicated, will give considerable trouble all through the growing season. Let the plants be grown in pots that have wire handles attached so that they can be suspended. A compost of sphagnum-moss and leaf soil, with which are incorporated a few small crocks and some silver-sand, will suit their requirements.

Platyclinis.—Such species as P. glumacea, P. Cobbiana, and P. uncata, although coming from the Philippine Islands, thrive well if suspended from the roof of the intermediate house. Afford them less water at the root from the present time until growth re-commences. Syringe them daily on the under sides of the leaves, and sponge them occasionally. In the same house, P. filiformis is now in full growth and showing its flower spikes; the plant will require abundance of water at the roots and copious syringings overhead until the flowers commence to open, but no longer.

Lælia pumila and its varieties are now starting to grow, and may be repotted if necessary. Grow them in shallow Orchid pans, with only a small quantity of compost, which should consist of peat, leaf soil, sphagnum-moss, some small crocks, and coarse silver sand. Suspend these plants in a cool part of the intermediate house, and keep the surface of the potting material just moist until the flowers appear in the young breaks, when the quantity should be increased until growth is completed. There are several distinct varieties of this species, as L. p. alba, L. p. delicatissima, L. p. Gatton Park variety, L. p. Low's variety, L. p. E. Ashworth's variety, &c., all of which should be obtained if possible. The flowers which are produced during October and November are sure to be appreciated, especially where flowers are required for buttonholes.

PLANTS UNDER GLASS.

By B. CROMWELL, Gardener to T. SUTTON TIMMIS, Esq., Cleveley, Allerton, Liverpool.

Souvenir de la Malmaison Carnations.—Select the more vigorous plants as they pass out of flower for immediate layering, for the earlier this is done the better chance will the young plants have of becoming rooted before the winter. If space can be afforded in frames in which early Potatos have been growing, little more will be required than to add a liberal addition of course sand with fine charcoal siftings to the soil in which the Potatos have been grown. The old plants, after being thoroughly watered, should be turned out of their pots and be planted into the prepared soil in the frame to such a depth that the shoots are conveniently low enough to be tongued in the usual manner. Secure each layer as the work proceeds with a strong peg or layering pin, and when the layering is finished afford water through a fine rose, after which place the lights on the frame and provide shade from bright sunshine. In the course of a week or so from the time of layering the lights may be removed on fine nights. Give a gentle spraying of clear water in the morning, after which replace the lights and take every precaution to prevent heavy rains from saturating the soil.

Cyclamens.—These plants, being well advanced, should now be placed in their flowering pots, using a compost of loam, good leaf-soil, dry cow manure, sand, and a little finely-sifted lime rubble; press the soil firm about the corms. Place the plants close to the glass in pits or in frames, in which a night temperature of 60° can be maintained. Afford shade, and maintain a humid atmosphere by frequently spraying the walls and the surroundings about the plants; and not forgetting to give light fumigations occasionally in order to keep the plants free from insect pests.

Re-arranging Plants in the houses.—Most kinds of hard-wooded plants will now have been removed out-of-doors, therefore their place in the conservatory, greenhouse, or corridor must be filled with other decorative plants. By grouping the different subjects together in their respective colours a better effect is produced. An abundance of material is offered for the purpose, and with a selection of plants from the intermediate house or stove (many of which will remain in flower for some time in the cooler structures), the conservatory can be made very attractive. Small groups of Streptocarpus set in a groundwork of Adiantum Ferns, an adjoining group of Schizanthus, with others of Gladiolus delicatissimus and its varieties; Anthurium Scherzerianum also set in Fern. Bougainvillea (Coker Court variety grown in small pots) make pretty groups of distinct colour. Acalypha musaica with spikes of Francoa ramosa interspersed have a charming effect. Begonias, Petunias, Abutilons, Chromas, Carnations, Cannas, and Celosias, all combine in making the conservatory and plant-houses attractive during the next few months.

THE FLOWER GARDEN.

By HUGH A. PETTIGREW, Gardener to the Earl of PLYMOUTH, St. Fagan's Castle, Glamorganshire.

The Delphinium.—At the present time there is no plant in the herbaceous border of hardy herbaceous plants more effective than the Delphinium, whether it be the annual or perennial varieties, though the tall hybrids of the latter are especially so. The great difference in their height, ranging as they do from 1 foot to 10 feet high, and their variety of colours from pure white to scarlet, and every shade of blue from bright lavender to deep indigo, make them splendid subjects for using in many ways, either in masses or groups of distinct colours, or as single border plants in combination with other plants. The effects of these combinations are sometimes very beautiful, and now that the Delphiniums are in flower it is a good time to make observations and to think of fresh effects that may be obtained from them next summer. Their cultivation is very simple, as they are perfectly hardy, and thrive in the most ordinary soil, provided it has been previously well manured and deeply dug. Seed sown now of the perennial sorts will supply flowering plants for next year, but if there are certain colours which it is desired to retain distinct the best plan is to propagate by dividing the stock of the particular plant, either in the autumn when the year's growths have ripened off, or in the spring just as the plants are starting into growth. It is advisable, too, to lift the perennial plants every three or four years, and trench the ground, and manure it thoroughly before replanting. This is best done in the autumn. Like a good many other flowering plants, if the flowering stems are cut away when the flowers fade, it encourages a second display later in the season. The annual varieties should always be sown where they are intended to flower, and thinned out when the seedlings are large enough to handle. If sown in boxes, and afterwards planted out, they are not nearly so successful. Amongst the species Delphinium nudicaule is a most desirable dwarf, compact, little perennial, about 12 inches to 15 inches in height, with light scarlet flowers, and is very easily raised from seed. On a light dry border it comes into flower very early, and lasts for a long time. It is most effective if grown in small groups. D. cardinale is another scarlet-flowering one, but is much larger growing. D. formosum, and its varieties belladonna and lilacinum are very effective, and worthy of a place in any border. D. azureum is another beautiful flowering plant with particularly large, sky-blue blooms. D. cashmirianum is one of the dwarf species and of a distinct pale blue colour, and well worth growing. D. Zalil, which has long spikes of beautiful clear yellow flowers, attaining 3 feet or more in height, an annual, is very pretty, while Queen of the Blues, and Porcelain Blue, which has already been referred to in a previous note, should be in every collection because of its charming colour.

FRUITS UNDER GLASS.

By T. W. BIRKINSHAW, Gardener to Lt.-Col. Sir CHAS. HAMILTON, Bart., Hadley Park, Bedfordshire.

Figs.—Trees that are growing in permanent borders will furnish a second crop of fruits, providing they are in a healthy condition and free from red spider. Where the first crop has been gathered, the trees should be vigorously syringed both morning and afternoon, and should any insect pests be present they should be syringed two or three times in succession with Gishurst Compound well diluted with soft water. Growing shoots should be stopped at two or three nodes above the fruits, and any weak sprays or suckers that are not required should be removed. The second crop generally produces more fruits than the tree can perfect; not more than three should be allowed to each shoot. If the old mulching material is exhausted, a little more consisting of loam, decayed cow manure, and bone meal should be applied. Furnish the roots with plenty of liquid manure, and endeavour to maintain a moist atmosphere in the house while the fruits are swelling. If the figs are to be sent long distances, it is important to gather them before they become too soft, or they will probably become bruised in transit.

Pot Figs.—It is a good plan to have a number of these plants in pots, for they can be forced or retarded as the grower wishes. If there is an unlimited amount of room in the fruit forcing departments, they can be arranged in batches to furnish successional crops. Negro Largo, Osborne's Prolific, and St. John are three good varieties for growing in large pots. The first-named must be severely restricted in root space, for it is a very strong grower, and will, if the root-run is not kept within bounds, produce large sappy growths and practically no fruit. This variety should certainly find a place where pot figs are grown. The fruits attain a good size, and they are of excellent flavour when properly finished.

Lady's Seedling Grape.—If the bunches of this variety are in course of ripening, and the foliage around them is at all dense, a few of the largest leaves should be tied back to admit the air and sunshine which will give additional colour to the berries. Give an abundance of clear water to the roots of vines whose fruits are commencing to colour, and allow plenty of warm air to circulate freely through the house. Keep a sharp look-out for thrip and red spider, and sponge the leaves on the first appearance of either of these pests.

THE APIARY.

By CHLORIS.

Honey Dew.—Honey dew, instead of being such a blessing as the old skeppists imagined it to be, is a great curse to bee-masters. In some parts it is almost impossible to obtain a section free from honey dew.

What Honey Dew is.—The substance is produced by an aphis which secretes honey dew and sprays it over the leaves, and sometimes such quantities are produced that it falls from the upper leaves to the lower portions of the trees. This sugary moisture attracts the bees and wasps, during a lull in the honey flow, and it is gathered and stored by the bees. These aphides secrete honey dew, it would seem, as a measure of self-protection. In the natural course of events the insects would be destroyed by birds, but the bees and wasps, desiring the sweet product, drive the birds away.

What it looks like.—If a shallow frame or section be held before a strong light, honey dew looks inky, or, perhaps a better way of describing it would be to say it has a smoky appearance. When tasted it certainly has a smoky flavour. Never, under any circumstances, offer for sale honey contaminated with this horrid stuff.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, *as well as specimens and plants for naming, should be addressed to the* **EDITOR, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Special Notice to Correspondents.—*The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.*

Illustrations.—*The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c., but he cannot be responsible for loss or injury.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.*

Local News.—*Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

APPOINTMENTS FOR JULY.

SATURDAY,	July 7	Soc. Franç. d' Hort. de Londres meet. German Gardeners' Soc. meet.
TUESDAY,	July 10	Roy. Hort. Soc. Summer Exhibition at Holland House, Kensington (2 days). Wolverhampton Floral Fête (3 days).
WEDNESDAY,	July 11	Nottingham Hort. Sh. (2 days). Hereford and W. of England Rose Sh. Helensburgh (Scotland) Rose Sh.
THURSDAY,	July 12	Woodbridge Flower Sh. Bath Rose and Begonia Sh. Potters Bar and Dist. Rose Sh. Manchester & North of England Orchid Soc. meet. Weybridge & Dist. Fl. Sh.
FRIDAY,	July 13	Sweet Pea Sh. in the Exhibition Grounds, Garryowen, Limerick (2 days).
SATURDAY,	July 14	Glasgow Fair. Dutch Gardeners' Soc. meet.
TUESDAY,	July 17	Roy. Hort. Soc. Coms. meet. Roy. Scottish Arboricultural Soc. Exh. at Peebles (4 days).
WEDNESDAY,	July 18	Nat. Rose Soc. & Roy. Caledonian Hort. Soc. combined Exh. at Edinburgh. Glasgow Pansy Sh.
THURSDAY,	July 19	Newport Fl. Sh. Roehampton Cottage Fl. Sh. at Dover House. Dunfermline (Carnegie Trust) Fl. Sh. (2 days). Great Yarmouth Fl. Sh.
FRIDAY,	July 20	North Lonsdale (Ulverston) Rose and Sweet Pea Exh.
SATURDAY,	July 21	German Gard. Soc. meet.
TUESDAY,	July 24	Nat. Carnation & Picotee Soc. Sh. in Roy. Hort. Hall, Westminster.
WEDNESDAY,	July 25	Cardiff & County Hort. Soc. Exh. (2 days). Newcastle-upon-Tyne Fl. Sh. (3 days). Dingwall Fl. Sh. Ewell Cottage Gardeners' Sh.
THURSDAY,	July 26	Ulster Hort. Sh. (2 days). Bridgwater Fl. Sh. Scarborough Fl. Sh. (2 days).
FRIDAY,	July 27	Roy. Bot. Soc. meet.
SATURDAY,	July 28	Dutch Gard. Soc. meet. Peterston-super-Ely, Cardiff, Fl. Sh.
MONDAY,	July 30	Roy. Hort. Soc. Conversazione, 9 p.m.
TUESDAY,	July 31	Roy. Hort. Soc. International Conference on Plant Breeding (3 days). Llanelly Fl. Sh.

AVERAGE TEMPERATURE for the ensuing week, deduced from observations of Forty-three Years at Chiswick—63·2°

ACTUAL TEMPERATURES:—

LONDON.—*Wednesday, July* 4 (6 P.M.): Max. 74°; Min. 52°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—*Thursday, July* 5 (10 A.M.): Bar., 30·1, Temp., 69°, Weather—Fine.

PROVINCES.—*Wednesday, July* 4 (6 P.M.): Max. 70° Eastern Counties; Min. 51 Orkneys.

SALES.

WEDNESDAY, JULY 11th—

Special Sale of Orchids, comprising the "Hey House" collection, and 600 Established Orchids in variety. Orchids in flower and bud, at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 1.

The Transition in Agriculture.

We have heard it said, even within the walls of the R.H.S., that Horticulture is less progressive than Agriculture, and less disposed to profit by the teachings of Science. Considering the prosperity of horticulture and the depressed condition of agriculture generally, this has always appeared to us as being a very hard saying. No doubt the speaker, an eminent agriculturist, had some good reason for his statement, but beyond the fact that gardeners are often content to purchase artificial manures, weed-killers, insecticides, &c., at much higher prices than the up-to-date farmer would do, we cannot see much reason to exalt agriculture at the expense of horticulture, but rather the reverse. There can be no sort of doubt that as a rule the gardener gets a much larger output from the soil he cultivates than does the farmer, and whilst the latter is, not without reason, complaining of hard times, the former is, on the whole, progressing.

The farmer has not been able to adapt himself and his procedures to altered conditions. This is a misfortune for which, of course, he is not wholly responsible. Whether by co-operation, or the adoption of methods and practices found profitable in Denmark, in Holland, and other countries, or by amended land-laws, reduced taxes and lessened rates of transit, a remedy may be found, we do not propose now to enquire. That no one panacea that will operate at all times and under all conditions is likely to be forthcoming may be inferred from the failure of the fruit-crops for the last year or two—a failure, we regret to say, that bids fair to be repeated this season, though possibly not to so large an extent.

Fruit culture under glass is another matter, and under fruit culture we include not only that of Grapes and Peaches, but of Tomatos and Cucumbers. The enormous increase during the last few years of the area devoted to the production of these fruits is almost beyond belief, except to those whose business affords them an opportunity of realising it. These "fruits" have come to be almost a necessity, and whilst the bulk of the wheat and cereals we consume must, under any circumstances, be imported from abroad, we can, and do, supply the markets from our own resources with much of the produce alluded to. No doubt we could and should do much more in this way were it not that it is cheaper at certain seasons to buy from the foreigner or from our fellow-subjects across the sea than it is to grow it at home.

We have so far been speaking of "necessaries," or of what may be fairly considered as such. The culture of flowers for decorative purposes may be looked on as a luxury, though a harmless one. When one comes to consider not only the gratification given to the consumer and the benefits, moral and intellectual, he derives from the exercise of his taste, but also the enormous extent to which both the labourer and the capitalist are benefited by the culture of flowers, it becomes evident that the line between necessaries and so-called luxuries is by no means of the hard and fast description. The acres upon acres of glass now devoted to the cultivation of Roses, Carnations, Chrysanthemums, and other flowers represent, on the whole, a very large capital and a correspondingly large income to the cultivator and to those employed by him. Then, again, there are the great seed-farms, the collectively large areas devoted to the open-air cultivation of Daffodils and other market flowers, as well as of Strawberries and small fruits. These are all illustrative of the fact that while ordinary farm-culture has declined, garden-culture has largely increased. Some farmers have had enterprise enough to enter the ranks of market-gardeners and rose-growers. They are few in number, perhaps, but, as many of our readers know, they have been conspicuously successful.

To those who wish to learn more of the way in which gardening methods are replacing the old farming systems, we commend the perusal of Mr. Edwin Pratt's "Transition in Agriculture," published by John Murray. It is full of interesting and varied details, and written in so pleasant a style that its perusal is a very agreeable task.

FLOWER SHOW ARRANGEMENTS.—It is very unfortunate that two special societies should have arranged to hold their exhibitions on the same day. It is equally or more unfortunate that the promoters of these gatherings should not have considered the interests of the horticultural Press to which they are under such obligations. By selecting Thursday as the day on which to hold their exhibitions, they practically preclude the possibility of preparing an adequate report. Some of our contemporaries are published at an earlier date than we, and as for ourselves, while Rose-lovers are revelling in the exquisite colour and form of the Rose and the devotees of the Sweet Pea are feasting on the beauty and fragrance of their favourite flower, we shall be inhaling the perfume of printers' ink and be more or less stunned by the rattle and din of the printing machines. The invitation to avail ourselves of the amenities of the Club Room at the Botanic is rather ironical under the circumstances! We shall give a short notice of each show in this present issue.

A GREAT SUMMER SHOW AT HOLLAND HOUSE.—Readers may be reminded that by the kindness of MARY Countess of ILCHESTER the Royal Horticultural Society will hold an exhibition in the grounds at Holland House, Kensington, on Tuesday and Wednesday next, July 10 and 11. The show is organised on exactly the same lines as the Temple show, but catching a later series of plants in perfection. There will be also a special tent for sundries. This will be the fifth great summer show the society has held in succession, and hitherto every one of them has entailed a loss on the society's finances. The shows have been magnificent, but the attendance has never compensated for the outlay. The site of the show is very centrally situated, and is easily accessible from all parts of London. Holland House lies due west of Hyde Park and Kensington Gardens, and is within five minutes' walk of four railway stations. Visitors from the City and West End will find the Holland Park (Tube) Station, on the Central London Railway, very convenient. Those travelling from Kew, Ealing and the Western Suburbs will find the electrified District Railway a good route; or they can take a tram to Hammersmith Broadway, and thence an omnibus to the entrance gates. Note.—Kensington High Street is the nearest station on the Metropolitan and District Railways from Liverpool Street, King's Cross, St. Pancras, Euston, Paddington, Cannon Street, Charing Cross and Victoria. Addison Road is the nearest from Waterloo, Clapham Junction, Willesden and Richmond. Earl's Court is the nearest from Wimbledon, Putney, Fulham, Acton, Ealing, and Windsor. It is convenient to change at Earl's Court for Kensington High Street. All Hammersmith and Turnham Green omnibuses pass the gates, from

Liverpool Street, Bank, King's Cross, St. Pancras, Euston, Charing Cross and Hammersmith. The only entrance to the show will be by the Great Gate in Kensington High Street, and the only exit by the gate leading to Melbury Road, where carriages may be ordered to wait. An arrangement has also been made with the Royal Meteorological Society for an Exhibition of Meteorological Instruments, comprising rain-gauges, sunshine-recorders, barometers, thermometers, photographs illustrating meteorological phenomena, diagrams illustrating the influence of the weather upon garden and other crops, &c., and also a typical open-air Climatological Station in working order. Mr. WILLIAM MARRIOTT, the Assistant Secretary of the Royal Meteorological Society, will give a short address each day at 3.30 p.m. on "Meteorology in Relation to Gardening," and will explain the nature and working of the instruments shown.

THE GARDENING CHARITIES.—By the kindness of MARY Countess of ILCHESTER the beautiful gardens of Holland House will be open to visitors from two o'clock till seven on July 10 & 11, the occasion of the Royal Horticultural Society's Flower Show; admission 1s. each, the proceeds to be given to the Gardeners' Royal Benevolent Institution and the Royal Gardeners' Orphan Fund.

FLOWERS IN SEASON.—Mr. R. LINDSAY, of Murrayfield, Midlothian, kindly sends us specimens in flower from the open garden of VERONICA LYCOPODIOIDES, a dwarf shrub from New Zealand, with erect branches, densely covered with small scale-like, decussate leaves, which might readily induce the observer to think he was dealing with a Cypress-like Conifer or a Lycopod. Microscopical investigation would, of course, soon dispel the illusion, and if, as in this case, the flowers were present, there could be no doubt as to the affinity of the plant. VERONICA HECTORI is very similar, but coarser in habit, and the leaves are rounder and less acuminate.

ABUTILON VITIFOLIUM, with its bluish lilac flowers, has been sent us from various places in the south this year; but this is the first time that we have seen it from so far north as the neighbourhood of Edinburgh. Mr. LINDSAY tells us his plant is hardy but is afforded the protection of a south wall.

ASTRAGALUS ALPINUS is rare enough in Britain, being confined, we believe, to the mountains of Clova (Forfar and South Aberdeen, Watson), but the white variety found on Ben Vrackie, in Perthshire, is still more rare. The specimen sent is from a seedling from the original plant.

MR. JOHN WRIGHT, V.M.H.—The *Agricultural Economist* for July contains an excellent likeness of this eminent gardener-journalist, whose works on pomology and fruit culture have secured for him a prominent place among the elect, and whose labours in the promotion of horticultural education in country districts give him a high place among the benefactors of the country.

THE BRUSSELS BOTANIC GARDEN. — The *Matin de Brussels* is now discussing a project for transferring the collections of the State Botanic Garden to the splendid park of Woluwe. The botanic garden would be kept, but the interior of the buildings would be transformed into a Kursaal, with concerts, refreshment rooms, &c., and other attractions. The projectors of the scheme propose to make at Woluwe a new Kew Gardens, which, as is stated, is the world's model for such institutions.

DRESDEN ORCHID SHOW.—We have received the schedule of the International Orchid Exhibition to be held at Dresden in May, 1907, and which comprises 49 classes for which good prizes are offered. Mr. OTTO BEYRODT, of Marienfelde, Berlin, who has taken the lead in most of the recent Orchid exhibitions in Germany, will give information on the subject of the show, and forward schedules to all who apply to him.

NEWLY-NAMED PLANTS. — A correspondent sends us the following note. A plant-seller in Farringdon Road, London, has the following notice hung on his stall:—"Sturgeons, 3d. doz.; Dayliars, 1d. each. All plants sold from this stall are warranted true to name." The Sturgeons are supposed to be what gardeners call Nasturtiums. But gardeners must not be in a hurry to throw stones, for they mean Tropæolum when they say Nasturtium, just as they mean Pelargonium when they say Geranium.

BRITISH FORESTRY.—Mr. HERBERT ROBERTS having asked in the House of Commons what steps have been taken to carry into effect the recommendation of the Department Committee of 1902 on British forestry, Sir E. STRACHEY says: 1. The Departmental Committee recommended that the Alice Holt Woods, in Hampshire, should be made available as soon as possible to serve as a demonstration area in England. This has been done, and the recommendations made by Dr. SCHLICH are being systematically carried out. A certain amount of experimental planting has already taken place. It was also recommended that a suitable estate should be purchased in Scotland to serve as another demonstration area. Two additional properties are now under consideration, and as soon as a suitable estate has been found the Treasury will be approached with a view to purchase. 2. The recommendation of the Departmental Committee that lecturers should be appointed at Oxford and Cambridge has to some extent been met by the augmentation of the salary of the Sibthorpian Professor of Rural Economy at Oxford (Dr. SOMERVILLE), who is now Professor of Forest Botany. It is understood that an estate will be placed at his disposal for demonstration purposes. 3. A sum of £500 a year, which was placed by the Treasury at the disposal of the Board for the establishment of lectureships in forestry, has been allocated to the University College of North Wales at Bangor and to the Armstrong College at Newcastle-on-Tyne. The results have been most encouraging, and there has been a constant demand on the part of landowners for expert advice from the lecturer. 4. A school for working woodmen has been established by the Commissioners of Woods and Forests in the Forest of Dean, and is now in the third year of its existence. 5. Legislation will be necessary to remove the inequality in the levy of the estate duty on timber. 6. The Railway Fires Act, which comes into force on January 1, 1908, will give some protection to owners of woods against loss by fire caused by sparks from locomotives. 7. Special inquiries were made in 1905, with a view to ascertaining the extent of land now occupied by woods in Great Britain, and the results have been published in the agricultural returns for that year. 8. With the object of ascertaining the districts in which local authorities have developed the catchment area of their water supplies by afforestation. The results of various enquiries were tabulated and published in the Journal of the Board of Agriculture for November, 1904. A leaflet on the relation of woods to domestic water supply was published in January, 1904, and a large number of copies have been issued.

Photo by J. Gregory.

FIG. 6.—MESSRS. PERKINS AND SONS' (COVENTRY) 1ST PRIZE EXHIBIT IN THE CLASS FOR A BRIDE'S BOUQUET AT THE R.H.S. SHOW HELD ON JUNE 20.

THE FLORA OF CHINA.—We have received the following letter from Mr. W. BOTTING HEMSLEY, F.R.S., keeper of the Herbarium, Royal Gardens, Kew:—"I believe that all who have read Mr. E. H. WILSON'S admirable series of articles on his last mission to China for Messrs. VEITCH & SONS, which have appeared in the *Gardeners' Chronicle*, and on which you made some comment in your last issue, will agree with you that a few words of appreciation and congratulation will not be out of place. Messrs. VEITCH may be congratulated on having selected a man, recommended by the authorities at Kew, who has so ably served them and science, and Mr. WILSON deserves the highest commendation for the very thorough manner in which he conducted his work. He might have been commercially successful, without troubling himself about the botany of China; but with Messrs. VEITCH'S financial support [and the additional outlay must have been very considerable] he must have devoted every minute of his waking hours to work. Having had exceptional opportunities of learning the extent and character of his operations in China, not only from his living and dried collections, but also from other travellers and residents in China, I have no hesitation in ranking him with DAVID DOUGLAS and JAMES DRUMMOND, whose labours in North America and West Australia respectively are so well illustrated in our gardens, herbaria and botanical records. Having also been associated with him in comparing some portions of his enormous dried collections, presented to Kew by Messrs. VEITCH, I was agreeably surprised at the highly critical botanical knowledge he displayed."

A FIRE-RESISTING TREE. — Mr. ROBERT THOMSON writes: "At the time of the vast conflagrations which have destroyed the great city of San Francisco, it has occurred to me that the following brief account of a fire-resisting tree will be interesting. This plant (Chaparro) is indigenous to the Republic of Colombia, with regard to which, I think, the only record of its peculiar merits is that which I have published. The London *Daily Telegraph* ten years ago (October 12, 1895) epitomized my report on the subject as follows: 'It is not often a student will turn to a Foreign Office report in expectation of finding aid to Biblical exegesis, but anyone who reads Number 370 of this year will perceive that the outward

and visible tokens of an unconsumed burning bush are not incompatible with the facts of nature. It has always been difficult to show how a plant could burn and yet not be consumed—a spectacle that so struck Moses that he called it "this great sight." It may be that the bush was like one of the stunted trees described in the Foreign Office report just mentioned known as the Chaparro, which resists fire for a very long time. The branches of it burn slowly, but the trunk is practically fireproof—indeed, it appears to be a vegetable salamander, and flourishes best in the midst of great prairie fires. If a long period elapses without a conflagration, the Chaparros pine away and even die, but the moment the flames burst out and roar and hiss among the vegetation, then the incombustible bushes begin to look bright and to flourish. Places reduced to sterility by incessant burnings are occupied by this diminutive tree, and assume the aspect of vast systematically formed and well kept parterres. ROBERT THOMSON, Halfway Tree, May 25, 1906."' The plant to which Mr. THOMSON refers is, as we learn from Mr. HOLMES, a species of Rhopala. Its fire-resisting property is due to the abundance of crystals of mineral matter which it contains in its bark.

ONE OF THE HEAVIEST RAINFALLS recorded in London for many years—over 2 inches in less than nine hours—began shortly after midnight on Thursday, June 28, and continued till about 9 a.m. on the following day. Extensive flooding occurred in various parts of the metropolitan area. The rain and floods were experienced over a wide area outside London. Two inches of rain means about nine gallons to every square yard or 202 tons to every acre.

CHRYSANTHEMUM "TOKIO."—A recent number of the *Revue Horticole* contains a coloured figure of a remarkable "Japanese" variety with long linear florets, the central ones being of a paler colour. The variety was obtained by Messrs. VILMORIN, ANDRIEUX & Co. in 1903. It has been cultivated in various manners. The florets are tubular in the beginning, but afterwards flatten out. The plate shows them of a violet colour, but in the text we are assured that this is an error arising from some accident during printing, and that the true colour is delicate rose. M. PHILIPPE DE VILMORIN adds that it is one of the easiest varieties to cultivate and that it succeeds in the open air without any special care.

THE ABERDEEN AND NORTH OF SCOTLAND COLLEGE OF AGRICULTURE.—The governors of this college have just issued their prospectus for 1906-07. It extends to 50 pages. The prospectus states that a lecturer in forestry will be appointed to provide instruction in that subject, and to organise short courses of instruction for working foresters who cannot spare the time for a longer course. A forest garden or demonstration area is to be provided in connection with the forestry department. This will contain specimens of forest trees and demonstration-plots, showing methods of propagating, planting, and cropping. A new departure is a course of lectures to be given in districts desiring information on horticultural subjects. These will deal with garden plants: the duties performed by root, stem and leaf; the soil, its constitution in relation to plant life, the working of the soil, gardening implements and fertilisers; vegetables: the origin, uses and methods of cultivation of well-known sorts; fruits: their origin, uses, and cultivation, methods of pruning and training; methods and principles of budding and grafting; herbaceous, annual, and other flowering plants; greenhouse and room plants; the propagation of plants by division, layers, cuttings, &c.; the improvement of garden plants by selection and crossing; the ailments of garden plants, methods of prevention and cure. Altogether the prospectus provides for a wide and liberal course of instruction admirably suited to carry out the main object of the college—the development in the North of Scotland of education and research in agriculture, horticulture, forestry, and allied subjects.

THE ROYAL BOTANIC.—We have received sundry documents relating to the affairs of this society. Horticulturists of all grades are lamenting the unfortunate condition in which the society is now placed. With a vivid remembrance of a similar crisis in the affairs of another society, of the manner in which it was extricated, and of the eminently successful manner in which it is now carried on, we can only hope that the "Botanic" will decide on a policy which will justify its name, enable it to carry out the objects for which it was founded, and make it representative rather than exclusive. It must be remembered that even in the darkest hours of the Royal Horticultural Society much was done for horticulture, in spite of the attempts to turn the garden at South Kensington into a tea-garden, for the benefit of the residents in the neighbourhood.

MR. W. SMITH, who is leaving Oxenfoord Castle, after having had care of the gardens there for the past 23 years, was recently presented by his friends and neighbours, at the Stair Arms Hotel, with a gold watch chain and pendant, Mrs. SMITH being also given a gold bracelet. Expressions of regret on Mr SMITH leaving Oxenford Castle were voiced and he was wished every success in his new appointment at Lambton Castle, Durham.

SCOTTISH HORTICULTURAL ASSOCIATION.—This association held its annual outing on Saturday, June 30, a visit being paid to Floors Castle, Kelso. The company, which numbered 75, was favoured with fine weather. They were conducted over the gardens and grounds by Mr. STREET, head gardener to His Grace the Duke of ROXBURGHE. Those famous gardens were greatly admired, an especial feature of interest being the magnificent lawns. The crops of Figs were remarkably fine, especially of the variety Brown Turkey. Carnations are also well grown in these gardens both under glass and out of doors.

UNSEASONABLE FLOWERING. We frequently see instances of this in the Horse Chestnut arising from different circumstances, but we do not remember to have noticed it in the Lime. Several trees planted in a London suburb by the side of the roadway some 20 or 30 years since are now full of bloom, whilst their companions are showing rapidly ripening fruits. As all the trees are growing under apparently similar conditions, and are of about the same age, there must be some individual peculiarities to account for the difference. While speaking of the Lime may we point out to intending planters that the Lime is one of the most unsuitable trees for planting in or near large towns?

THE NATIONAL CHRYSANTHEMUM SOCIETY'S OUTING will take place on Monday, July 23, when a visit will be paid to Dorking. By kind permission of Her Grace LILY Duchess of MARLBOROUGH members will inspect the gardens at Deepdene, and later a visit will be made to Broom Hall, by permission of Sir ALEX. HARGREAVES BROWN. Particulars may be obtained from the secretary, Mr. RICHARD A. WITTY, St. James' Villa, Swains Lane, Highgate, N.

LIBERAL PRIZE FOR A NEW ROSE.—Prizes of the value of £150 for new plants or flowers are uncommon, and deserve to be recorded. A prize of this amount (3,000 marks) was offered at the recent exhibition of the German Rose Society (Verein Deutscher Rosenfreunde), held at M. Gladbach, June 29-July 2, for the best seedling Rose of German origin not yet in commerce, the donor being the *Praktischer Ratgeber*, a weekly horticultural journal published at Frankfort-on-the-Oder. A committee of five of the judges of the exhibition was appointed to make the award, and from the several seedlings entered they finally selected a rose-coloured Hybrid tea, which appeared from the blooms staged to be an improvement on both Caroline Testout and La France, and the seedling will receive the prize, subject to its habit of growth in the grounds of the raiser satisfying the judges, and on condition also of the production of good flowers fit for being exhibited in the autumn of the present year, in order to prove its autumn-blooming qualities. The raiser of the seedling in question is Mr. H. KIESE, of Erfurt, and one condition of the prize is that the Rose shall bear the name "Otto von Bismarck."

Publications Received.—*Transactions of the Royal Scottish Arboricultural Society*. Vol. xix., Part 2. The contents include papers on the Possibility of Artificial Manures in Forestry, Planting Wasteland for Profit, Protection of Young Spruce from Frost, and many articles on kindred subjects.—*Bird Notes and News*. Vol. ii., No. 2. Pleads the cause of birds and the need for their intelligent protection.—*Agricultural Journal of the Cape of Good Hope*. June. Leading features: Extra-tropical Forestry (continued), by D. E. Hutchins, Tobacco Wilt in Kat River Valley (illustrated), Culture of Chicory, and Export Fruit Trade.—From the New Zealand Department of Agriculture, Divisions of Biology and Horticulture we note the following Bulletins: No. 7, Potato Diseases, by T. W. Kirk; No. 8, Nitrogen—fixing Bacteria, by T. W. Kirk; No. 9, Meteorology in Relation to Farming, by Rev. D. C. Bates; No. 10, Canker of Fruit Trees, by T. W. Kirk and A. H. Cockayne; No. 11, Club Root of Cabbage, by T. W. Kirk and A. H. Cockayne; No. 12, Hollyhock Rust, by T. W. Kirk and A. H. Cockayne; No. 13, Gum-tree Scale, by T. W. Kirk; No. 14, Disease of Swede Turnip, and No. 15, Bean Diseases, both by T. W. Kirk.—Also the Thirteenth Report of the Divisions. Excellent work has been done under the greatest disadvantages caused by removal of the offices and laboratories, and Messrs. Kirk and Cockayne and their assistants have devoted much private time in endeavouring to cope with the situation—From the same source we note Technical Paper, No. 1. A. The Facultative Saprophytism of Alternaria Solani, by A. H. Cockayne, and B, On Termites, by Captain T. Broun.—Michigan State Agricultural Experiment Station. Report of the South Haven Sub-Station for 1905. By L. R. Taft and T. A. Farrand. Successful work is chronicled, chiefly in connection with fruit-growing.—*The Garden City*, June. —*West Indian Bulletin*, Vol. VII., No. 1. This contains a report of the agricultural industries of Montserrat, papers dealing with Cotton and Rubber, and with the sources of the nitrogen of vegetation.—*Insect Pests of the Farm and Garden*, F. Martin Duncan (Swan, Sonnenschein & Co.)—*Irish Gardening*—*Fruit Culture Charts* (W. H. & L. Collingridge). —*La Tribune Horticole*.—*Nos Arbres, Correvon* (Geneva Atar).

NEW SWEET PEAS.

NOTHING is more marvellous in the history of horticulture than the evolution of the Sweet Pea, which has only been equalled by that of the Chrysanthemum. [Surely the development of the Begonias is, morphologically, even more remarkable than either?—ED.] This gradual development of its floral capabilities was doubtless largely owing to the genius of the late Mr. Henry Eckford, whose long-promised reminiscences, regarding which he wrote to me some years before his death, I trust may yet appear. At his request, I wrote at that time an "Appreciation" of the Sweet Pea, to appear in the same volume. His son, Mr. John Stainer Eckford, has already given us two varieties of commanding beauty, viz., Queen Alexandra and Henry Eckford. The former is a flower of splendid texture, a vigorous grower, and unquestionably the deepest pure scarlet self that has appeared. It is in many respects a great advance on the Scarlet Gem, which it may, not improbably, entirely supersede. Unlike its famous predecessor, it does not require to be grown in the shade. Its exquisite contemporary, Henry Eckford, is worthy of the world-famous name which it bears, and that, in the light of the Eckfordian creations,

is saying much. Its flowers, which are large and of splendid substance, are of a beautiful shade of rich salmon-orange, and will doubtless be highly artistic in their effect. In my own garden I have planted it in harmonious association with Queen Alexandra, Sadie Burpee, and Duchess of Sutherland; so it will doubtless be seen to great advantage with such a fine environment.

Mr. Lester Morse, the great American hybridist, who has given to the world many interesting varieties, recently sent to me from San Francisco, just before the conflagration, a most attractive classification of modern Sweet Peas, in which my own Eckfordian namesake, among many others, has the honour of being described. The characterisations are for the most part distinctive and expressive. Mr. Lester Morse has also forwarded to me his famous varieties raised by himself, viz., Helen Pierce and Shasta, of which the former resembles in its unique colour a blue mottled Gloxinia, the background being white; while the latter may be described as an improved Emily Henderson. The great American rival of Mr. Morse is Mr. Wm. Atlee Burpee, of Philadelphia. One of his latest and finest productions is entitled Burpee's Earliest White, which, judging from its reception at the hands of competent cultivators, is likely to prove a considerable acquisition. Navy Blue, I presume, was raised by Mr. Burpee. If so, he must rejoice in its continued popularity, though like many susceptible varieties, it has its limitations.

Among recent introductions of British origination, what may be termed the Countess Spencer types or hybrids (?) have a distinguished place. These, with their exquisitely varying shades of delicate pink, could not easily be surpassed. They are at present receiving great prominence in America, where they are described, not inexpressively, as "orchid-flowered types." Gladys Unwin and Florence Spencer are among the most graceful and attractive of these.

As the gratifying result of cross-breeding, we have now an almost incomparable scarlet Sweet Pea, Queen Alexandra; an orange variety of most refined beauty, Henry Eckford; a pure white surpassing Sadie Burpee, at least in dimensions, Dorothy Eckford; several blues, mauves, and dark purples of great distinction and numerous lovely roseate emanations, each more effective than its predecessor, from Prima Donna and Countess Spencer. What we earnestly desire and confidently anticipate is a decisive yellow, of more emphatic colour than the Hon. Mrs. Kenyon, like that which is discoverable in certain Tea Roses of considerably deeper than pale primrose hue, notably in the beautiful Perle des Jardins. *David R. Williamson.*

ODONTOGLOSSUM QUEEN ALEXANDRA, VARIETY "CARMEN."

OUR illustration (fig. 7) represents a flower of this fine hybrid Odontoglossum obtained by crossing O. Harryanum and a fine form of O triumphans, and for which De B. Crawshay, Esq., Rosefield, Sevenoaks (gr. Mr. Stables), secured an Award of Merit at the Royal Horticultural Society, June 26. Several forms of the cross have been previously shown, but the variety Carmen was by far the largest and finest in colour-features which have no doubt been developed considerably by cultivation at Rosefield, where Odontoglossums are the speciality and their culture is scientifically and satisfactorily carried out. The sepals and petals of Carmen have a clear yellow ground colour, but the greater part of the surface is taken up by dark chestnut-red blotches. The lip is white. The basal half around the yellowish crest is beautifully marked with deep violet colour.

NURSERY NOTES.

MR. L. R. RUSSELL'S.

In the Richmond Nursery, which is comparatively new, the glass department is largely devoted to the cultivation of choice foliage plants. It would be difficult to find a better stock of Aralia elegantissima, A. Veitchi, A. gracillima, and A. leptophylla than is seen here. All are well furnished with foliage and are in perfect health, the plants being of various sizes from those recently grafted to others 2 feet to 3 feet high. Cordylines (Dracænas) are also well cultivated, and include many choice sorts, such as Jamesi, The Queen, Rose Laing, Duchess of York, Alex. Laing, and Superba. The plants are perfect specimens for table decorations. A nice batch of Acalyphas was seen. Caladiums are another feature in this nursery, the varieties Rio de Janeiro, Le nain Rouge, Mrs. Luther, Lady Stafford Northcote, Mikado, Her Majesty, and many others being especially good. Nice specimens of Codiæums (Crotons) are seen, and they include a fine stock of Aigburth Gem, Golden Ring, Elvira, Mars, Mutabilis, Harry Green, and Reedi, with many more of the better sorts. Heliconia illustris is grown in larger quantities than is usually seen. Anthurium crystallinum was noticed in good health and vigour, while A. Warocqueanum and other kinds grown for their foliage are also well done. A. Veitchi should be especially mentioned. Marantas are another feature, and the stock includes all the better sorts, such as Sanderiana, argentea, Veitchi, metallica, zebrina, and others. It is evident that the propagation of these plants is well understood in these nurseries, as is shown by the healthy stock of young plants. With all foliage plants much depends upon the propagator and the material used, and it is evident that in Mr. Russell's nursery that these facts are recognised. Alpinia Sanderiana, seen in a large batch of useful sized plants, showed its superiority over A. vittata, which was growing under the same conditions. Anoectochilus, of the most beautiful leaved varieties, including Madame A. Bleu, Sanderæ, Comte de Kerchove, and others; Sonerillas; Phyllanthus nivosus—small plants with beautifully coloured foliage—are all worthy of note. Other choice foliage plants are equally well grown, all the houses being well filled with useful stock.

Much of the nursery outside is devoted to the cultivation of Euonymus and other hardy foliage plants. Tree Ivies, of which large quantities are grown as standards, are a great feature. The varieties Arborea aurea, Silver Queen, elegantissima, and others were very fine. Silver Queen is a favourite for growing as a dwarf pot plant. Of deciduous trees, Japanese Maples, Cornus Spathi aurea, Quercus concordia, Ulmus punctata variegata, and Dimorphanthus mandschuricus variegatus are grown in large quantities. The Golden Privet and several of the choicer Ligustrums are also extensively planted, L. japonicum variegatum being specially worthy of note.

The branch establishment at Isleworth is largely utilised for propagating stock for the other branch nurseries. Several houses were filled with Aucuba vera; these had just passed their flowering stage and they showed promise for a splendid crop of berries. As growers of this plant, the firm has been noted for some years. Eurya latifolia is grown in large quantities, and the stock was remarkably clean and healthy. Elæagnus, in about ten distinct sorts, including E. glabra, E. præstans, E. aureus, E. macrophyllus (the silver leaf) are extensively propagated. Of Bamboos is seen quite a large collection, Arundinaria falcata being a special favourite. Azara integrifolia variegata was very pretty. Ulex hispanica, in pots, was very bright with its flowers. Climbers are extensively grown, and young plants of Clematis occupy several houses. It was of interest to note that many of these plants are propagated from cuttings, of which large batches are already rooted, and they were looking very promising. Vitis Coignetiæ, V. Thompsoni, and V. dissectum are all plentifully grown. Stock plants of many choice subjects

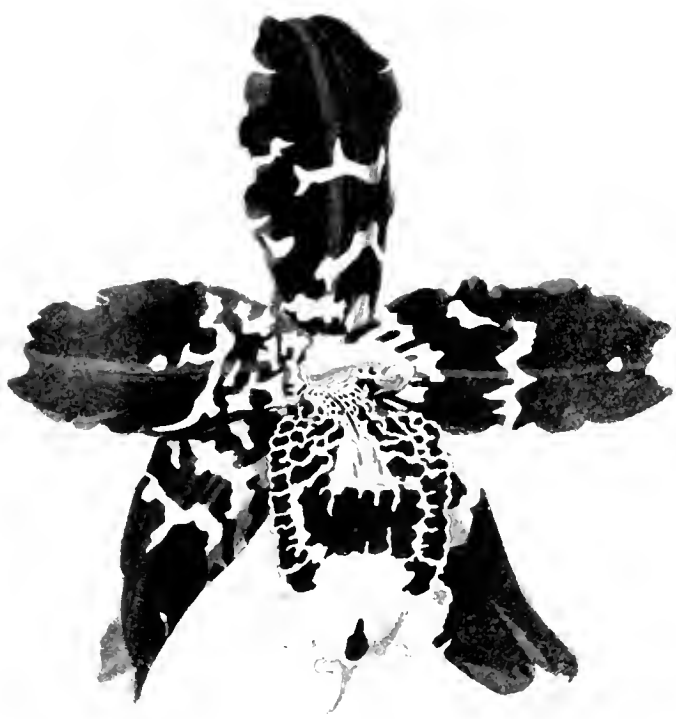

FIG. 7.—ODONTOGLOSSUM QUEEN ALEXANDRA, VARIETY "CARMEN."

were flowering against the walls. Ribes speciosum has been a mass of flowers. Olearia stellulata and O. Gunni were also beautifully in flower, with Ceanothus dentata, C. Gloire de Versailles, and C. Veitchiana. Solanum jasminoides is found to be hardy in these nurseries, and it flowers well in the open against a wall. Cotoneaster horizontalis was covered with its pretty berries.

Several glasshouses that are used for the culture of half-hardy plants during the winter are now filled with climbing Roses, of useful sorts, including the new varieties of Ramblers, hybrid Teas, &c. The Roses were well advanced in growth, and they will be placed in the open at an early period to ensure well-ripened growths. The new growths of the Ivies and Euonymus had suffered considerably from the late frosts, but they were fast recovering at the time of my visit on June 7. *A. H.*

WILD FLOWERS FOR CUTTING.

GARDENERS, as a body, do not always appreciate the value of wild flowers for cutting. Yet, if carefully selected, they are as pleasing as the usual run of border flowers, and, by those whose knowledge of plants is not extensive, some of them might probably be regarded as offerings from the mixed border. One might recommend the use of wild flowers in a cut state on account of its preventing, to some extent, the indiscriminate use of garden-flowers for the purpose. But even in the case of the first-named it is possible to overstep the limits of neighbourliness when rare blooms are gathered for one's own gratification merely. Children ought to be taught to appreciate and preserve our native wild flowers as well as our own wild birds. The little ones invariably rush for the first flowers of spring, but if it is pointed out to them that they are depriving others of the pleasure of seeing that which, on account of its scarcity, is in effect a rare blossom, the tendency to gather flowers thoughtlessly is checked. I have made it a point to always check my own children from gathering wild flowers when only a few were in bloom, because the next passer-by would be the loser. Trippers from town are frequently to blame for gathering rare flowers, but once let them fully comprehend that the impulsive gratification of a momentary whim will result in the deprivation of those who follow in their steps of much pleasure, it will surely have a tendency to check the custom of picking, only to throw away, all kinds of flowers and vegetable greenery. But, apart from the thoughtless destruction of wild flowers, there is no good reason why they should not be used, and used extensively. Some of them—Primroses, Bluebells, and others—cherished for long centuries, have always been picked. Besides these, there is a large number that are every whit as desirable as the majority of garden flowers, and some afford a variety of tint and form that does not exist in the latter. Care in the selection of flowers is, of course, essential. In general, those which are the produce of dry, impoverished soil are unsuitable, because they last only a short time in a cut state. Nor is it proper to gather wild flowers at any time of the day. Early in the morning or in the evening when the dew is falling are the best times to cull wildings, and the stems should be placed in water directly home is reached. A limited number of kinds is best cut in the bud. Poppies and Globe flowers, for instance, and Foxgloves, with, perhaps, only the lowermost bloom expanded. One has, of course, to be satisfied with such flowers as are only found in the locality, but sometimes a walk of a few miles brings one to a flora quite distinct from that of one's own neighbourhood, and not a few plants localise themselves in certain spots, and there alone is it of any use to look for them. Some people like flowers which others dislike. Sweet Cicely is one such, and there are others which association condemns—Dock, for instance.

Distinct types are to be had among wild flowers, such as the Umbelliferæ, some of the members of which are not only pretty, but, once used, become indispensable. How bold and handsome is the Cow Parsley! How light and graceful the Hedge Parsley! Good, too, for mixing with other flowers is the Earth-nut, and how charming are the old stems and heads of the Wild Carrot!

The Compositæ include many well-known and much-liked flowers, the Corn Marigold and Horse Gowan being too well known to need commendation. I like the soft yellow Leopard's-bane, and send quantities of it to London every year during the season. Some folks may object to the Tansy, but when cut with stems 4 or 5 feet in length it forms a handsome addition to the flowers of autumn. Nor must we forget that its scent, which is so generally disliked, is apparent only when the leaves or flowers are handled. I have also an appreciation for the Goat's Beard, perhaps as much on account of the foliage as the flower, and for Hieracium aurantiacum, sometimes as bright as a Pelargonium, and H. Pilosella. What a beautiful plant, too, is the Wild Succory, but, unfortunately, not common. Then in Pyrethrum and Matricaria other good things are found, while Centaurea provides the well-known Blue Bottle and C. nigra, the dried stems and flower-receptacles of which are so pretty in winter. Scabiosa succisa, especially the white form, is worth noting, while the Red Milfoil and Double Sneezewort are garden flowers rather than weeds; and I have no objection to Crosswort. In Teasel we have handsome and effective materials for decoration, and if it were not so common I would place beside it the Burdock, or, at least, the strong, vigorous stems of it. Vervain is useful for the same purpose as these, providing a setting to bulky flowers. For the same purpose the flags of Wild Iris should not be overlooked, nor the long blade of Reed Grasses, the Rushes, and the large Horsetails and Docks in seeds in autumn.

A few species of wild flowers provide good blue colour. Succory has already been mentioned. There are, too, the deep blue Bugloss, Forget-Me-Not, and the Wood Myosotis, Rampion, Bluebells (Scilla and Campanula), and Bellflowers and Horned Rampion. Rampion, Bluebottles, and Fennel make a pretty and simple combination. It is only of late years that the flaunting Poppy has come to be regarded with approval as a flower for picking. Mingled with Oats or Wheat it is lovely, and, if cut just previous to expansion, and the stems placed in water without delay, it will last for quite a week in a cool apartment. The Toadflax and Corkle and the light Bluebottle, along with just a few Poppies, make a charming arrangement. The Periwinkle is another most useful plant, though one can hardly term it wild. I prefer the large Periwinkle, with its bold, expanding shoots and shining leaves, to the creeping, smaller one. Of yellow wild flowers, the glowing Marsh Marigold is probably the finest of all. Ranunculus acris and R. lingua are also effective, and the Globe Flower must not be overlooked, its foliage, as well as its "lockit" cups, being pretty. Valerians, though rather fugacious, are distinct and good, and those who have the pretty Pink Valeriana pyrenaica in their neighbourhood possess a gem. Of Orchids, the best are Orchis maculata in its varied forms, O. latifolia, and Habenaria Conopsea.

I have not touched on the wealth of beauty we possess in our indigenous woody vegetation. The Sloe, Cherry, Crab, Wild Plum, Berried Elder, Barberry, Euonymus, the young foliage of Oak and Birch, the surpassing beauty of some of the Willows, the dainty catkins of the Hazel, the Honeysuckle, the Wild Roses, Raspberry, Bramble, Wild Clematis need only to be named to impress on our minds the delights of our own country and the unlimited means within our reach for rendering our homes sweet with flowers and cool with foliage. *R. P. Brotherston.*

[We confess we look with apprehension on our correspondent's proposal. With very few exceptions, our wildings never look "at home" anywhere but in their natural surroundings, and for decorative purposes are mostly less suitable than garden productions grown for the purpose. The indiscriminate and wholesale gathering of our wild flowers, especially of the rarer ones, should be condemned, for it prevents the production of seeds. To give a money value to such plants is to lead to their extermination. Even now there is scarcely a Primrose to be seen within a dozen miles of London.—ED.].

KEW NOTES.

OXALIS ADENOPHYLLA.

THIS new and rare species is now in flower in the Alpine House at Kew. It forms a charming companion to the beautiful Falkland Island species, O. enneaphylla, resembling it to a certain extent, especially in the foliage, which is hardly distinguishable. The chief point of difference lies in the rootstock, which in O. adenophylla is large and bulb-like and clothed with matted fibres, while in O. enneaphylla the rootstock is rhizomatous. The rosy purple flowers have deeper coloured veins with a deep crimson centre, and are produced in pairs or threes on each stem, instead of singly as in the Falkland Islands species. O. adenophylla was found by Mr. H. J. Elwes in Chili in 1902, on the tops of mountain ranges near San Martin, at an elevation of 6,000 to 7,000 feet, growing by rivulets above the timber line. He presented plants to Kew, and they flowered in the spring of 1905, when it was drawn and afterwards figured in the *Botanical Magazine*, t. 8054. So far the plants have been grown in pans in a cold frame, but it is apparently as hardy as the other, and will probably succeed under the same conditions in a moist, shady place on the north side of a large block of stone. Although the plants have not produced seeds they have been increased by division, so that there will soon be enough to make a group in the rock garden. The individual flowers do not last long, but are produced freely in succession for a considerable time. *W. I., June 30.*

TREES AND SHRUBS.

JUNIPERUS CEDRUS.

FOR the last few years I have been much annoyed at the want of success I have experienced in raising plants from the "bays" (berries) of this remarkable and nearly extinct tree of our flora. Those to whom I sent seed have until now been equally unsuccessful, and Mr. Raffill reported last March from the Temperate House, Kew, that none of the seeds sent by me had germinated. At last I have found out a very simple way which has answered very well, and that is to soak them for a long time in water. I extracted the two or three very hard seeds contained in the berry and put them into ordinary water for fifteen and thirty days respectively at a temperature of about 70° Fahr. In about six weeks after sowing, seedlings were noticed in both lots.

Now that I have succeeded in raising plants easily from seed, and that at Kew Mr. Rathll

has reproduced this very rare tree also quite easily from cuttings, no difficulty ought to exist in propagating this valuable species in different parts of the world. It is said to be the quickest growing of all Junipers, and its scented timber, not unlike that of Juniperus Bermudiana, is reputed imperishable. Dr. Carl Bolle saw trees in the heights of the island of Palma (Canary Islands) which he estimated to be a thousand years old.

I am now trying a way suggested by Mons. Correvon as likely to make these seeds germinate (by soaking them in a weak acid solution for six hours). Before finishing, I will add that hitherto, by plain sowing of the berries, I had only succeeded in obtaining two plants (after sowing a great number of berries), but by the above simple means I consider the difficulty quite solved. *George V. Perez, Puerto, Orotava, Teneriffe, June 14, 1906.*

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

Housing of the Workers.—It may interest your readers to know that a Conference on Housing will be held at Letchworth (Garden City) on Saturday, July 14, at 3 p.m., under the auspices of the Christian Social Union. Papers on "Rural Housing" and "Co-partnership in Housing" will be read by Lady Gwendolen Cecil and Miss Sybella Gurney respectively, and the discussion will be opened by Mr. Henry Vivian, M.P. The housing problem underlies much of our social misery. So much is admitted, but what are we each doing to cope with it? Let us go down to Letchworth and see what they are doing there; let us consider whether these conditions of air and space and room to live may not be made the conditions of our British children everywhere, and not only in one or two favoured Garden Cities. How great a task lies before us, if this is to be accomplished; and how much need there is that men and women of good will should consider together how it may be done, and what they can do to help the work! All who are interested in the subject are invited to attend the Conference, and it is hoped that they will also take the opportunity of seeing what has now been done at Garden City, and especially of looking at the cottages belonging to the Garden City Tenants, Limited, which have been built round open spaces and greens, avoiding the usual mean street altogether. Any further particulars may be obtained from the Secretary of the Conference, Mr. Fredk. Litchfield, 22, Red Lion Square, W.C. *Henry Scott Holland (Rev.), 1, Amen Court, E.C. June 27, 1906.*

The Season in the Garden.—With us the untoward season, the combination of premature warmth and consequent growth of plant life in February, with the very severe frost of the middle of March, and the continuous cold winds and low temperature ever since till a short time ago, have brought about an accumulation of influences damaging to plant life such as I have never seen anything to approach. All tender leaves which began to develop a month or six weeks ago are stunted, twisted, and curled. Mildew is almost universal. Even Laurels have it all over the tenderer leaves, and in many instances in the old leaves, even. It is also on such things as Beech trees, Oaks, Birches and Lilacs. The Rose bushes are all curled up and deformed by it, and even the most vigorous kinds, which a few days ago were free, are now attacked. Green fly and brown fly (aphides, of course) are in such quantities that it is quite hopeless to try and do anything against them in a large Rose garden such as I have, and, perhaps worst of all, rust is over very nearly all the plants; leaves are turning yellow and dropping off by the thousand. Red rust, which I have scarcely ever seen in my garden before, is alarmingly prevalent amongst the Roses, and nearly all the first blooms are defective, with short-stunted petals, and in the midst of them a huge development of green centres, which spoils the flowers utterly. From such strong Roses as Mrs. Paul, Madame Isaac Pereire, and Wm. Allan Richardson, I have had to cut away the greater portion and by far the greater number of the first blooms. My gardener told me that a neighbouring farmer who has a very fine plant of W. A. Richardson growing in the front of his house and covering a porch, has thousands of blossoms, but he had not been able to find a single properly-formed Rose upon it. My fruit trees are dropping what seem to be well-formed fruits, Apples and Pears. I think the wood never ripened properly last autumn. After the end of last August we never had a day when it was pleasant to sit out of doors, and it was constantly wet, with chill rain. Even quite lately we had two or three days when the sun did not shine, and the maximum shade temperature was from 54° to 56°. *En revanche*—and it is the only thing I have to set against all this—I have a very good hay crop—I treat my field very liberally, and I am sure it pays, and if the forecast of this morning is at all justified I shall get it in very well, as I began to cut it yesterday, and it should be all down to-day. But amongst the curious peculiarities of the season is that cut flowers generally are not lasting at all, as they usually do, and as to the plants, the flowers of Rhododendrons and Wistarias have not lasted more than two-thirds of their usual time; the same with Thorns' Lilacs and Laburnums. I have one very curious development which is quite new to me. Three years ago I planted a hedge of Penzance Briars about 50 yards long; there were about 10 varieties. They have done very well, and at this moment the hedge is extraordinarily beautiful. My wife and I both noticed last year that many were coming with a double row of petals instead of the single one with which we began. This year most have two rows of petals, several have three, and some even four. Only two varieties have remained altogether single. I don't know if I have been too liberal to them, but I have never had such a thing happen to me before with any single Rose. *Southampton, June 19.*

Pilfering Botanists.—Complaints are being made just now by the keepers of the Aberdeen Public Parks concerning the depredations of students. No doubt, botanical research is a thing that very few citizens would feel it in their hearts to discourage, and more especially by young men who are studying for examinations, but when this research is carried out in the beautiful plots in the city parks, much to the destruction of natural art and beauty, there is good ground for objection. It has been a common practice recently for Aberdeen students to indiscriminately pull up the flowers and tear them to pieces; and this, too, without so much as "by your leave." Needless to say, a stricter watch is being kept, and it is hoped those young men will take a thought and mend their ways. *Aberdeen.*

A Severe Hailstorm.—A heavy hailstorm visited this neighbourhood on the night of Saturday, June 23. In these gardens glass to the extent, roughly, of about 2,000 panes, was broken. Gloxinias in a small house were riddled by the broken glass. Begonias, Caladiums, and other soft leaved plants also suffered. Crotons had branches broken by the falling glass, whilst the plant-houses were not the only parts of the gardens to suffer. Unfortunately Apples and Pears were knocked off ruthlessly, and many that are left present the appearance of having been struck with a stone. The more forward Strawberries were nearly all damaged, and Gooseberries, Currants, &c., covered the ground instead of the trees. Vegetables were also injured, and in some instances completely destroyed. Potatos in some cases were denuded of their leaves and presented nothing but the naked stalks. The beds of Onions looked as though boys had thrashed them with sticks, and Spinach and Lettuce had the appearance of having been trampled on. Clumps of Rhubarb have not a sound leaf left, nor has Gunnera in the pleasure grounds. A more complete wreck than the gardens presented it would be difficult to find. Cartloads of small twigs and leaves covered the ground in all directions. The hailstones were like broken ice and as large as Walnuts. Many were flat, and would completely cover a penny piece. The largest measured was 5 inches round. *E. Dumper, The Gardens, Hinton Admiral, Christchurch.*

"Partridge Canes."—Perhaps the most popular walking-stick at the present time is that known as the "Partridge cane." In the *Guide to the Kew Museums*, No. 2, Monocotyledons and Cryptogams (1895), p. 53, it is stated that these canes are "the stems of an unknown palm, largely imported from China." Investigations prove the canes in question to be the stems of Rhapis flabelliformis. This well-known palm, introduced into this country as long ago as 1774, is native of the woods and ravines of Southern China generally. It is also cultivated in the same regions, in the warmer parts of the Yangtsze Valley, and in Japan. For export the culms are cut down when 6 to 8 feet high and dried. The fibrous leaf-bases are removed and used locally for rope and mat-making. The "canes," now smooth and clean, are packed in bundles, covered with matting, and are ready for export. In this country the outer siliceous covering of the stems is removed, exposing the black fibrous structure of the wood, from which the name, "Partridge cane," is derived. These canes have been largely imported into this country for the last quarter of a century or more. Nearly all are exported from the Canton River delta to Hong Kong, and from thence to Europe and America. Rhapis humilis, Blume, and R. major, Blume, are probably merely forms of R. flabelliformis, and are here regarded as constituting one species only. *E. H. W.*

SOCIETIES.

ROYAL HORTICULTURAL.

Scientific Committee.

June 26th.—*Present*: Dr. M. T. Masters, F.R.S. (in the chair), Sir J. Llewelyn, Bart., Revs. W. Wilks and G. Henslow, Prof. Boulger, Messrs. G. Gordon, H. Gussow, A. W. Sutton, E. M. Holmes, S. Pickering, J. W. Odell, and F. J. Chittenden (hon. sec.).

Azalea dying.—From Rugby came an Azalea which had suddenly gone off. No fungus or insect could be detected thereon, and it was the opinion of the committee that death was due to allowing the plant to become dry at the roots at some time.

Clematis "sporting."—Mr. Gordon showed double pale lilac flowers of Clematis which had appeared on two Clematis plants, which last year bore the usual dark flowers of Clematis Jackmanni and a small white flower respectively. It was thought that in all probability the flowers had been produced by the upgrowth from the stock on which the Clematis plants which flowered last year had been grafted.

Ascidia on Plumiera.—Mr. J. W. Odell showed some curious examples of these cup-like growths proceeding from near the base of the leafstalk of Plumiera lutea, looking exceedingly like stipular growths. Such structures are common on Cabbages, Lettuces, and Pelargoniums, but do not appear to have been recorded hitherto in Plumiera.

Shoot of Hyacinth Growing Downwards.—Prof. Boulger said his attention had been called to the growth of a Hyacinth, the bulb of which has been scratched out of the soil, and had lain on the surface with the shoot (which had just started growth) pointing downwards. The shoot continued to grow downwards to a depth of about 8 in., and produced flowers which, however, were not coloured. Prof. Henslow said that he showed a plant with a similar growth some years ago. In that case, however, the bulb had been planted upside down. It would appear that in such cases the power of response to the stimulus exercised by gravity is very slight.

Yellow Rose from Palestine.—Mr. A. W. Sutton read a letter from a correspondent concerning a yellow Rose which grew near Baalbeck, specimens of which he also showed. Dr. Masters recognised the Rose as Rosa lutea, and Sir John Llewellyn said he had seen it growing so profusely on the northern slopes of Mount Lebanon as to make a mass of colour visible at the distance of a mile. (See p. 11.)

Seedling of Delphinium "Belladonna." Mr. Sutton also showed flowers of some seedlings raised from seed produced by Delphinium Belladonna last year. This has not been known to produce seeds, at least since 1857, when the first record of the plant seems to have been made. A few seeds had been produced in the previous year, but none of these had proved fertile. The flowers of some of the seedlings resembled D. Belladonna very closely, but some more nearly approached D. formosum, and one bore flowers of a very beautiful deep blue tint.

Cannibalism among caterpillars.—Mr. Spencer Pickering said that in the course of some experiments with insecticides several larvæ of the winter moth had been kept together in captivity, and in one of the cages a caterpillar

had devoured all its companions, and others which had been supplied to it; eleven had been devoured in all, and the cannibal had grown to about four times its normal size. It has now turned into a chrysalis. It will be interesting, said Mr. PICKERING, to see whether the progeny of the moth will also possess carnivorous habits. It was remarked that several species of caterpillars showed cannibalistic propensities under certain circumstances; Mr. HOLMES thought this was the case particularly when water was withheld from them.

"Silver leaf" in Plums.—Mr. SPENCER PICKERING also said that he had been conducting experiments with this disease, which had been attributed to the fungus Stereum purpureum, a specimen of which he showed from a diseased tree at the meeting of the committee on October 24 last. A plantation of 112 young Plum trees had been made, and of these seventy-four had not been inoculated with the fungus, while thirty-eight had small pieces of the fungus inserted in their stems. Of the former none had developed the disease, while of the latter twenty-eight showed the characteristic silvering of the foliage within six weeks of the inoculation. This experiment confirms the results already obtained by Prof. PERCIVAL.

Diseased Irises, &c.—Mr. WORSLEY sent rhizomes and flowering stems of Iris pallida and Iris cuprea apparently attacked by the bacterial disease of Iris, concerning which a communication was read from Mr. MASSEE at the last meeting. Mr. WORSLEY said that his stock of I. pallida had been destroyed, most of I. cuprea, and all of I. Milesi, while some of I. gigantea had been killed and I. chinensis injured. I. germanica seems almost immune in his garden, while I. fœtidissima and I. Pseudacorus are entirely so. He also sent leaves of Crinum yemense from outdoors and under glass with leaves dying and becoming soft. C. Powelli, C. scabrum, C. giganteum, and several others had been similarly affected, but none of the plants had died. C. Moorei seems exempt. Dead leaves of Cordyline indivisa vera came from the same source, and C. australis had been attacked in the same manner. These plant diseases will be reported on at a future meeting.

Pæonies Dying.—B. C. WILLIAMS, Esq., F.R.H.S., of Henington, Dorchester, sent specimens of Pæony attacked by the fungus Botrytis pæoniæ (Sclerotinia pæoniæ). The shoots droop before the flower opens, and just above the surface of the soil a white web of fungal thread may be seen spreading over the surface of the stem. Later resting bodies or hard lumps (sclerotia) of a black colour are formed both above and below the surface of the soil. The diseased shoots should be removed and burnt as soon as discovered, and fresh stable manure should not be used for mulching. If plants have been attacked, it is well to remove the old soil from about them, and replace it with fresh soil with which lime has been mixed. This should be done in the spring.

Plants exhibited.—A newly-introduced Begonia, B. Pogget, from Kasai, Congo, having deep green leaves about 4 inches in length and 2 inches in width, only slightly oblique at the base, and small pink flowers in lateral clusters, the pistillate flowers having a fusiform ovary nearly 1 inch in length, showing no trace of the wings that are usual in the genus, was shown by the Director of the Botanic Gardens, Brussels. A Botanical Certificate was unanimously awarded to this plant on the ground of novelty and curious structure.

Abnormal Flowers of the Foxglove.—Mr. C. W. H. CREAVES, of Pwllheli, N. Wales, sent drawings illustrating the abnormal flowers of a self-sown Foxglove (Digitalis purpurea). The plant is a vigorous one, with normal foliage and eight racemes bearing some forty or fifty flowers each. A few of the flowers at the lower part of the raceme are normal, but the majority on each raceme exhibit the following marked variations (from the normal). The corolla is markedly bilabiate; the odd (anterior) petal hanging down in a manner suggestive of the labellum of certain Orchids. The filaments of the anterior pair of stamens—which are usually parallel to those of the posterior pair—curve outwards sharply at the points, where the upper and lower "lips" of the corolla diverge. The most curious feature, however, is that at the anterior edge, and near the tip, of each of the antero-lateral petals there is a single well-developed anther lobe. The latter are of the usual yellow colour with purple spots, and they contain pollen grains which appear quite normal under the microscope. There is no indication of filaments leading up to these anther lobes. The peculiar interest of these abnormal flowers appears to me to lie in the staminoid petals; for, although petaloid anthers are of quite common occurrence, the converse metamorphosis is, in my experience at any rate, a rarity. I may add that the plant bearing these flowers has possibly been superfed by the somewhat free use of liquid manure; but this, according to the generally accepted theory, should have induced what Göethe would have termed "retrogressive" metamorphosis, instead of the opposite tendency here exhibited.

(Photo by Rivers, Bath.

FIG. 8.—ANNA OLIVIER, A WELL-KNOWN TEA ROSE. FLOWER GLOBULAR, OF PALE BUFF COLOUR.

Abnormal Growth of Rhododendron.—Dr. MASTERS showed a drawing of a shoot of Rhododendron (R. Aucklandi × R. Fortunei) from Sir E. G. LODER, Leonardslee, Horsham, cut from a plant about twenty years of age, bearing solitary, imperfect, axillary flowers in the axils of leaves of the current season. The shoot was much elongated and showed a case of precocious flowering, the flowers, which should normally have opened next season, having developed this. The specimen was, moreover, particularly interesting from the fact that not only had the shoot elongated, but the bud scales had developed in the form of foliage leaves; the flowers were distorted in various ways.

Diseased Plants, &c.—Several other examples of diseased plants were exhibited, including Vine leaves with warts, Vine leaves attacked by red spider, Apple leaves with Fusicladium, &c.

LINNEAN SOCIETY.

JUNE 21.—Dr. A. Smith Woodward, F.R.S., Vice-President, in the Chair.

Miss L. S. Gibbs, F.L.S., read an abstract of her paper, "A Contribution to the Botany of Southern Rhodesia," illustrating her remarks by lantern slides from her own negatives. The collections on which the report was based were obtained in August to October 1905, at the end of the dry season. The air is dry and the sun's rays very strong, temperature from 80° to 90°, so that the country presented a burnt-up aspect, and the trees were bare, except a few evergreens. The veld is systematically burnt, to promote young growth for cattle-food, to the detriment or destruction of trees and shrubs. Distribution of species is wide, and the present paper tends to a confirmation, with many new records. Twenty-three new species are described, amongst the more interesting being the grass Erianthus teretifolius, Stapf, and a characteristic Elephantorhiza.

Mr. Carruthers, F.R.S., F.L.S., then read his paper on "The Authentic Portraits of Linnæus," with lantern-slides. He recalled the fact that in 1899 he made the subject the chief topic of his address at the anniversary meeting on May 24 of that year. He subsequently visited Sweden, Germany, and the Netherlands to inspect the originals, and read a paper detailing his results at

the general meeting held on November 19, 1891; a transcript of his remarks had been prepared, but it did not satisfy him, and nothing was published. The approaching bicentenary celebration of the birthday of Linnæus, for which the Swedes have been making extensive preparations, had induced him to revise his old transcript, and add some recently ascertained facts, which he now submitted to the Society.

The third paper was by D. Otto Stapf, F.L.S., entitled "Plantæ novæ Daweanæ in Uganda lectæ"; which, owing to the absence of the author due to a slight accident, was briefly introduced by Mr. T. A. Sprague, F.L.S., who had contributed some of the descriptions in the paper.

Mr. M. T. Dawe, Officer in charge of the Forestry and Scientific Department of the Uganda Protectorate, made an expedition from Entebbe, through Buddu and the Western and Nile provinces of that territory. His collections were transmitted from time to time to Kew, and his report was issued as a Blue Book (1906, Cd. 2904) last April, it gave an account of his journey, with some rough illustrations of specially noteworthy plants. Much new light is thrown on distribution, and new species are described, amongst them the new genus of Rutaceæ *Balsamocitrus*, Stapf, and a new species of Warburgia (Canellaceæ). As an appendix Mr. Dawe gives a summary of his report on the vegetation of the country traversed.

The reading of a paper by Sir Dietrich Brandis, K.C.I.E., F.R.S., F.L.S., "On the Structure of Bamboo Leaves," was postponed.

SOUTHAMPTON ROYAL HORTICULTURAL.

JUNE 27.—The summer show of this society was held on the above date in the county cricket ground, Southampton, the situation proving a desirable change from that of the Pier, the exhibition being a distinct success. Financially, too, the show was a greater success than formerly, when it was open for two days.

Roses were undoubtedly the feature of the exhibition. In the leading class for these flowers—that for forty-eight distinct blooms—there were five competitors. Messrs. HARKNESS & SONS, Hitchin, were distinctly ahead with large, shapely, well-coloured specimens, especially good flowers being those of White Lady, Horace Vernet, Mamie, Ulrich Brunner, Boadicea, Paule Lede, Duke of Teck, and A. K. Williams. 2nd: Mr. G. PRINCE, Longworth, Berks, with smaller examples.

For twelve triplets, Messrs. HARKNESS were again successful with high-class blossoms of Gabriel Luizet, Gustave Piganneau, Bessie Brown, Mamie, &c.

Tea or noisette Roses in twelve varieties were remarkably well shown by Mr. PRINCE, who easily secured the leading award in this class. Noticeable flowers were those of Maman and white M. Cochet, Comtesse de Nadaillac, and Mrs. E. Mawley.

Messrs. HARKNESS were successful in the class for six blooms of any dark-coloured Rose, while Mr. W. BURDEN (gr. to Lady Campbell), The Lodge, Bewbridge, I.O.W., was first in the class for six light-coloured flowers, with Mme. Cusin.

Garden or decorative Roses in twelve bunches were numerous and showy. Mr. G. PRINCE was first with a tastefully-arranged exhibit, but some of his bunches were of inferior merit. Clara Watson, Cecile Brunner, Madame A. Chatenay, and Papillon were the best examples.

Mr. ELLWOOD had much better flowers, but they were too tightly packed in the vases.

Mr. PRINCE was successful in the class for six bunches of single varieties.

In the gardeners' and amateurs' classes that for eighteen distinct varieties saw six entries. Mr. A. NEVILLE (gr. to F. W. Flight, Esq.), Cornstiles, Twyford, Winchester, staged high-class blooms that easily secured the first place. Prominent flowers were those of Mildred Grant, Captain Hayward, Boadicea, and Mrs. W. J. Grant.

Tea or noisette varieties were well displayed. Dr. SEATON, Woodside Cottage, Lymington, won the class for twelve blooms, Mrs. E. Mawley, Medea, and Souvenir d'Elise being his best examples. 2nd: Mr. A. MUNT, Hythe.

Sweet Peas were very meritorious. Mr. J. STEVENSON (gr. to the Duke of Hamilton), Mere'ey House, Wimborne, won Messrs. Toogood & Sons' prize for six bunches of these flowers among thirteen competitors.

Hardy Border Flowers.—Messrs. B. LADHAMS & Co., Shirley, Southampton, had the premier dozen bunches in distinct kinds, while for nine bunches Mr. H. MATTINGLEY (gr. to Lady Hopkins), Greatbridge House, Romsey, secured the first place with a bright display, including a huge sheaf of Gillenia trifoliata. Eight exhibits were seen in this latter class.

Plants were numerous and good. Mr. WILLS, Southampton, was first for a group of miscellaneous subjects arranged for effect.

Vegetables were splendidly shown, and added to the success of a fine show. In the class for six dishes of vegetables (Messrs. Sutton & Sons' prizes), Mr. E. BECKETT, Aldenham House Gardens, Elstree, won the premier place with an exhibit of superior quality.

No fewer than ten growers contested in the class for Messrs. Toogood & Sons' prizes for six dishes. Mr. ELLWOOD, with choice examples of Onions, Tomatos, Cauliflowers, &c., was distinctly ahead, and he also won Messrs. Carter's leading prize for vegetables.

NON-COMPETITIVE GROUPS.

Trade exhibits were numerous and good. Messrs. B. LADHAMS & Co., Shirley, Southampton, staged an interesting collection of herbaceous flowers, including a collection of Pinks, and a well-arranged rockery. (Gold Medal.)

Messrs. SUTTON & SONS, Reading, had an exhibit of Begonias, Gloxinias, Schizanthus, and Rhododendrons in pots; also Melons, Cucumbers, Tomatos, and Peas. (Gold Medal.)

Mr. C. W. BREADMORE, Winchester, had a large display of Sweet Peas of the leading varieties. (Gold Medal.)

Messrs. ROGERS & SONS, Southampton Nurseries, showed Roses in pots, cut Kalmias, and shrubs. (Silver-Gilt Medal.)

Messrs. E. HILLIER & SONS had an exhibit of cut shrubs and Roses. (Silver-Gilt Medal.)

ROYAL METEOROLOGICAL.

JUNE 20.—The final meeting of the session was held on the above date at the Society's rooms, 70, Victoria Street, Westminster, Mr. Richard Bentley, B.Sc.A., President, in the chair. Mr. E. J. Bellhouse read a paper on "The Mean Prevalence of Thunderstorms in Various Parts of the British Islands during the 25 years 1881-1905." The author gives the mean number of days in which thunder forms or thunder only occurred in each month, each season, and in each year at 53 stations situated in various parts of the United Kingdom. July is the month with the largest number of thunderstorms over Great Britain as a whole, and August at some places in the north of Scotland and north-west of England; while June is the stormiest month at nearly all the Irish stations. For the whole year the largest number of thunderstorms is over the northern and eastern parts of England, where more than 15 occur; while there are fewer than five in the west and south of Ireland and at most places in the north of Scotland. The summer distribution of thunderstorms is very similar to the annual distribution, while the winter distribution is quite different, when the largest numbers occur along the west coasts of Ireland and Scotland and extreme south-west of England.

Mr. W. H. Dines communicated a paper on a "Typical Squall at Oxshott, May 25, 1906."

ROYAL AGRICULTURAL.

The exhibits of the AGRICULTURAL EDUCATION ASSOCIATION have attracted a considerable amount of attention at the recent Royal shows. Until the formation of the Association, the value of the work done to advance agricultural science was minimised, because there was no endeavour to gather together the information gained from experiments and observations, or to co-ordinate the experiments made in the laboratory or in the field. In most advanced countries this is done by the State, but in England the principle of self-help or of individual enterprise is generally relied upon in matters relating to agriculture. Recognising this, those interested in agricultural education, seeing that the only way to ensure that the foundations of agricultural science might be placed on a firm basis, united in forming the association; and in this way a great step has been taken towards establishing an exact agricultural science. Its work is being recognised by the more important institutions associated with agricultural advancement, and is receiving their co-operation; but it is in no way allied to bodies which regard profit-earning as an object of their being. This year's exhibition aroused exceptional interest, and was associated with a forestry section, contributed to by several landowners and public bodies. Undoubtedly there is a strong wave of desire to leave the deep rut of prejudice which has been such a hindrance to progress in agricultural matters; and no better evidence of this could be found than the close examination that the crowd which thronged the exhibition made of the exhibits and the attention which they lent to the demonstrations. It has become recognised that at this exhibition there will be information as to the newest methods of treatment and illustrations of processes employed in research work.

Among matters of special interest at the Royal Agricultural Society's Show last week may be mentioned an exhibit from the AGRICULTURAL COLLEGE at Wye—the gooseberry mildew, which appeared in county Antrim in 1900. Unfortunately, little notice was taken of the disease at first; in fact, those who made the early investigations expected that it would not survive the change of climate from America, where it has done great injury for some years. However, in 1902 it appeared in county Derry, and in 1903 in county Dublin, and it has since spread over a wide area. Doubtless it will find its way to England in course of time. It is very important that the mistake made in Ireland should not be repeated, but that the infected trees should be burned at once. It appears in the months of May and June as a white mildew on the leaves, and this develops into a black scurf on the berries, making them unsaleable.

The CAMBRIDGE UNIVERSITY AGRICULTURAL EDUCATION DEPARTMENT had a number of specimens illustrating the Mendel law; but probably the most useful were those which bear on the rust in wheat. In the course of experiments in the cross-breeding of wheat, it was noticed that some varieties were practically free from the rust which afterwards develops into mildew, so destructive to the grain and straw), while others were very readily affected with it. Some of the plants resulting from crossing the readily-rusting varieties with those which had strong resisting powers were found to take the rust, and others not so. Observation showed that the proportion of rusting to non-rusting plants was constant, and followed the laws laid down by Mendel; consequently there is every reason to suppose that, even where a rusting variety is employed in the breeding, it will be possible to select a stock which will continue to be rust-resisting. This is the first year of observation on this point; but, if future experience shows confirmation, a most valuable weapon will have been found to combat the most serious disease affecting the wheat crop.—*Condensed from The Times.*

DUTCH HORTICULTURAL AND BOTANICAL.

AT a recent meeting the committee awarded First Class Certificates to Odontoglossum Harryanum var. Madame Hacke, from Mr. H. C. HACKE, Baarn (gr. Mr. Th. Hendricksen), the flowers of dark red, and of fine form; also to Cattleya Jean Hacke (Mendelii × Paskelliana), from the same exhibitor; this has white flowers of good form.

Certificates of Merit were awarded to Pyrethrum roseum fl. pl. Helena, a new plant from Mr. H. J. DE LANG, Oegsgeest, with flowers of pale yellow, tinted with salmon; Anguloa sanguinea, from Mr. C. J. KIKKERT, Haarlem, a strong plant with flowers of deep yellow, spotted with red; Cattleya Mossiæ Arnoldiana, from Mr. H. C. HACKE, Baarn, having white flowers tinted with light lilac, of fine form and possessing a good labellum.

Botanical Certificates were awarded to Scuticaria Hadweni, also from Mr. HACKE, the flowers are greenish yellow with brown spots; and to Sobralia macrantha, from Mr. HACKE, flowers large, beautiful, with sulphur-coloured throat.

A Silver Medal and a Bronze Medal were awarded to collections of 12 single and 12 double Pelargonium zonale in the finest varieties from Messrs. W. D. KELSSEN, DENANT & SON, at Aalsmeer.

NATIONAL ROSE.

VISITED BY H.M. THE QUEEN.

"If by each Rose we see
A thorn there grows,
Strive that no thorn shall be
Without its Rose."

JULY 5.—The annual metropolitan exhibition of the National Rose Society is taking place on Thursday as these pages are passing through the press. The show is held in the gardens of the Royal Botanic Society, Regent's Park, for the second time in succession. Previously the metropolitan exhibitions were held in the gardens of the Inner Temple, and in former years at the Crystal Palace. The present show is unusually extensive, and may be ranked among the largest the Society has ever held. Three large tents are employed, and still there is very little space to spare. Several honorary exhibits of a miscellaneous character are arranged in the corridor. In some of the AMATEUR Classes the competition is marvellous. In one, for instance, there are 36 boxes shown and in another 34 boxes. Shortly before 12 o'clock noon the show was visited by H.M THE QUEEN, who was escorted through the tents by Miss WILLMOTT, Mr. C. E. SHEA (President), Mr. ED. MAWLEY (Secretary), &c. The arrangements for the show had been made by Mr. ED. MAWLEY and Mr. E. F. HAWES, Superintendent of the Royal Botanic Society's gardens. The new seedling Roses have not been inspected, as we are compelled to leave the exhibition. The weather is beautiful, but the air in the tents is already becoming oppressively hot.

NURSERYMEN.

MIXED ROSES.

The Champion Trophy and Gold Medal in the Nurserymen's Section are always awarded to the winner of the 1st prize in the class for *Seventy-two blooms of distinct varieties*, which on this occasion is won by Messrs. B. R. CANT & SONS, The Old Rose Nurseries, Colchester. We cannot attempt in the short time at our disposal to enumerate the varieties, but must content ourselves with saying that the quality of the flowers is quite up to the usual standard of merit. Messrs. W. PRIOR & SONS, Mylands Nursery, Colchester, were second, and Messrs. FRANK CANT & Co., Braiswick Nurseries, Colchester, third. All the prizes at this show in this class will therefore go to one town, and that town in the extreme east of the country.

Forty distinct varieties (trebles).—In this very comprehensive class for trebles, there are four exhibits, including, therefore, 480 flowers. Messrs. B. R. CANT & SONS have the honour of winning the first prize with a beautiful collection in which the qualities of freshness and brilliant colour are more noticeable than that of mere size. Such brilliant flowers as Victor Hugo, Comtesse de Ludre, A. K. Williams, Captain Hayward, Edouard, Ben Cant, and Horace Vernet, with such pure white roses as Frau Karl Druschki, and pink ones as Carolina Testout, and lemon-coloured as Kaiserin Augusta Victoria present a fine effect. The second prize was won by Messrs. ALEX. DICKSON & SONS.

Forty-eight blooms, distinct varieties.—The judges had an unusually difficult task in adjudging this class, for there were as many as nine collections, most of them comprised of glorious and brilliantly-coloured flowers. At the very point of our leaving the first prize is given to Messrs. J. BURRELL & Co., and the second to Messrs. G. and W. H. BURCH.

Twenty-four blooms, distinct varieties.—The nurserymen's class for 24 blooms is usually a very favourite subject for competition, and the four competitors to-day are less numerous than might have been expected. Mr. CHAS. TURNER, Royal Nurseries, Slough, who has won the first prize in this class on so many previous occasions, has again acted up to tradition, and not only obtained premier honours, as also with Roses of very high quality. His varieties are Bessie Brown, A. K. Williams, Her Majesty, Duke of Edinburgh, Mrs. E. Mawley, Florence Pemberton, and Nestor. *Middle Row.*—Marquise Litta, Mildred Grant, Reynolds Hole, Marechal Niel, Horace Vernet, Frau Karl Druschki, Black Prince, and Maman Cochet. *Front Row.*—Mrs. J. Laing, Duke of Teck, The Bride, Chas. Lefebvre, Muriel Grahame, Mad. de Watteville, Niphetos, and Gustave Piganneau. Mr. JNO. MATTOCK, Headington, Oxford, is awarded the second prize, and Mr. WILL TAYLOR the third prize.

TEAS AND NOISETTES.

In the Tea and Noisette Roses there are very good flowers on view, and in the best collections there is much less disfiguration to be noticed on the petals than has been the case on some previous occasions.

Twenty-four blooms, distinct varieties.—There are five exhibits in this class, and the first prize is worthily won by Messrs. B. R. CANT & SONS, whose flowers are very lovely. Some of the best are Madame de Watteville, Ernest Metz, Golden Gate, Mrs. E. Mawley, Bridesmaid, and Cleopatra. Mr. GEORGE PRINCE, Longworth Nurseries, Oxford, is second, and Messrs. FRANK CANT & Co. third.

Twelve blooms, distinct varieties.—Out of seven exhibits in this class the best is shown by Messrs. J. BURRELL & Co., who had the following varieties:—Mrs. Ed. Mawley, Souvenir de Pierre, Notting, Bridesmaid, White Maman Cochet, Souvenir d'Elise Vardon, Maman Cochet, Mad. Hoste, Madame Cusin, Boadicea, Souvenir d'un Ami, Innocente Pirola, and Catherine Mermet. Second, Mr. JNO. MATTOCK, and third, Mr. GEORGE MOUNT, Canterbury.

ROSES IN BAMBOO TRIPODS, VASES, &c.

A very pretty display is made by collections of twenty distinct varieties, which are arranged in twenty bamboo tripods, the space occupied by each exhibit not exceeding 7 feet by 3 feet. The first prize in this novel class was won by Messrs. GEORGE COOLING & SONS, Bath, whose group contained H. T. and H. P. Roses, some of which, like Ulrich Brunner, Madame Jules Gravereaux, John Ruskin and Gladys Harkness, are of very fine quality; 2nd, Messrs. G. and W. H. BURCH, Peterborough; and third, Mr. CHAS. TURNER.

Fourteen distinct varieties of Teas and Noisettes (trebles) shown in fourteen vases.—Messrs. GEO. PRINCE, has won first prize in this class, and Messrs. D. PRIOR & SON has won second prize and Messrs. FRANK CANT & Co. the third.

Several classes are now arranged by the National Rose Society for exhibition varieties shown in vases, thus exploding the idea that was once common that such a system was impracticable for such varieties. In a competition for twelve distinct varieties, to include not more than six Teas or Noisettes, there were three exhibits, and Messrs. ALEX. DICKSON & SONS were awarded the first prize for a fine collection, embracing the following varieties, among others:—Marquise Litta, Countess of Annesley, Ulrich Brunner, Mrs. W. J. Grant, Caroline Testout, Lady Ashtown, which were shown best. Messrs FRANK CANT & Co. obtained second prize, and Messrs. D. PRIOR & SON the third.

DECORATIVE ROSES.

There are magnificent exhibits of these, but we cannot refer to them in detail. Mr. JNO. MATTOCK has an excellent exhibit in Class 14, and has won the first prizes in that class and in Class 15. The group of Roses shown by Messrs. PAUL & SON, The Old Nurseries, Cheshunt, in Class 16 is beyond praise, and Mr. GEO. MOUNT has a capital exhibit in Class 17, winning the first prize.

OPEN CLASSES.

Twelve Hybrid Teas, distinct.—The first prize in this class is awarded to Messrs. B. R. CANT & SONS for an even lot of perfect blooms. Very fine are the varieties Mildred Grant, which is the largest of them all, J. B. Clarke, Robert Scott, Bessie Brown, White Lady, and Caroline Testout are unexceptionable in size and condition. The second prize falls to Messrs. D. PRIOR & SON, very beautiful being the blooms of Caroline Testout, Liberty (a fine crimson), President Grant, Robert Scott, and Prince C. de Ligne. Messrs. ALEX. DICKSON & SON are the winners of the third prize, having half-a-dozen very fine blooms, and among them Mildred Grant, Marquise Litta, and Gladys Harkness.

Class 19.—In this class of 18 white or yellow Roses displayed in bamboo stands, the flowers make a telling display, and Kaiserin Augusta Victoria wins the first place for Messrs. S. BIDE & SONS, and Messrs. F. CANT & Co. take the second prize with Frau Karl Druschki, the third being taken by Messrs. BUNYARD & Co.

Class 20.—For 18 blooms of any other than white or yellow, Messrs. R. HARKNESS & Co. are first, and Messrs. B. CANT & Co. are second. This class is one of the best of its kind.

AMATEURS.

The CHAMPION TROPHY and replica offered for the best 36 blooms, distinct, was once more won by Mr. E. B. LINDSELL, being followed by F. DENNISON Esq. Mr. LINDSELL also won the Ben Cant Memorial prize. G. A. HAMMOND, Esq., won the Christy Challenge Cup, Lady CAMPBELL the President's Cup, E. J. HOLLAND, Esq., the Harkness Cup, and A. HILL GRAY, Esq., the Trophy for the best Teas and Noisettes, and the Prince Memorial prize.

NATIONAL SWEET PEA.

JULY 5.—The sixth annual exhibition of this society is being held in the Royal Horticultural Hall, Vincent Square, Westminster, as we go to press. The show is a great success, the number of entries totalling nearly one thousand. The exhibits entirely fill the hall and have overflowed into the two annexes, while most of the floral decorations are accommodated in the lecture room upstairs.

All the classes are well represented, and in addition many trade growers have staged large groups.

The floral decorations are a notable feature. Many new varieties being shown, some of superior merit, notably a buff-rose-coloured flower named Queen of Spain; Mrs. C. H. Curtis, a large rose-coloured flower, and Princess Maud of Wales, of a rich orange-carmine shade. A notable feature is the success of Mr. CHAS BREADMORE in the principal classes.

Eckford Memorial Challenge Cup.—No fewer than 46 collections were entered in this class, and nearly all these entries are staged. The trophy, which carries with it the Gold Medal of the Society, is of the value of 50 guineas, and is offered for 12 bunches in distinct varieties. This prize is secured by Mr. THOS. JONES, Bryn Penylan, Ruabon, N. Wales. His flowers are exceptionally robust, and are displayed on tall stems. The varieties are Black Knight, Dorothy Eckford, Countess Spencer, King Edward VII., Mrs. H. Sykes, Lady G. Hamilton, John Ingman, Mrs. R. F. Felton, Helen Pierce, Miss Willmott, Queen Alexandra, Romola Pizzani, Henry Eckford, and Helen Lewis. Second, Mr. Thos. Stevenson (gr. to E. MOCATTA, Esq.), Woburn Place, Addlestone. Third, G. D. FABER, C.B., M.P., Rush Court, Wallingford, Berks (gr. Mr. James Dymock).

In the special audit class for fifteen bunches of Sweet Peas ten displays are seen. The premier lot is shown by Mr. THOS. LEWIS, Bryn Penylan, Ruabon, N. Wales. The prize flowers are exceptionally large and bright, and are displayed on tall, stiff stems. Coccinea, Hon. Mrs. E. Kenyon, Gracie Greenwood (a beautiful vase), King Edward VII., and Mrs. W. Wright are all worthy of especial mention. Second, Mr. Thos. Stevenson (gr. to E. MOCATTA, Esq.), Woburn Place, Addlestone. Third, Miss BOOSEY, Bickley, Kent. The colours in the second prize exhibit are refined. Gladys Unwin and Mrs. W. Wright are especially good.

Collection of nineteen varieties.—Each variety was to be of a colour given in the Society's classification tables. Four competitors entered, the winner being Mr. CHAS. BREADMORE. Duke of Westminster (violet), Miss Willmott (orange scarlet), and Janet Scott (pink) are his best examples. Second, Messrs. G. & A. CLARK, LTD., Dover, with very large flowers. Third, Messrs. SALTMARSH, The Nurseries, Chelmsford.

Thirty-six bunches, distinct.—There are four good displays in this class, and great difference is noticed in the manner of staging. The second-prize group is well set up, the flowers being displayed on long stalks. Others are squat and too tightly bunched. The first prize is awarded Mr. BREADMORE for an even lot of flowers, of best form and colouring. A prominent variety is the bright red Queen Alexandra. Second, Mr. F. ACKLAND.

Twenty-four bunches, distinct.—This was a well-contested class. The first prize was won by Mr. JONES, Ruabon, N. Wales; second, Mr. S. HIBBENS, The Lodge, Ashford. Five exhibits were staged in this class.

Twenty-four bunches, distinct (open).—Entries in this class were numerous and of a high standard. The first prize was awarded to Mr. BREADMORE for a splendid display, the flowers having great substance and refined colours. The varieties Geo. Herbert and Lady Cooper may be mentioned as being especially good.

MARKETS.

COVENT GARDEN, *July 4.*

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday, by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate, not only from day to day, but occasionally several times in one day.—ED.]

Cut Flowers, &c.: Average Wholesale Prices.

REMARKS.—English Strawberries are plentiful and cheap. Supplies of Gooseberries are much shorter. English and Channel Islands Beans advanced in price very considerably during the week, and they are still realising good figures. There has also been a good demand for Tomatos, Peaches and Nectarines. Trade throughout the market has greatly improved. *E. H. Kidd, Covent Garden, July 4, 1906.*

POTATOS.

Lincolns, 40s. to 50s.; Duchess, 90s.; Jerseys, 6s. to 6s. 6d.; St. Malo, 5s. 6d. to 6s.; Cherbourgs, 5s. to 5s. 6d.; Dutch Rounds, 2s. 6d. per cwt. &c. *John Bath, 32 and 34, Wellington Street, Covent Garden.*

COVENT GARDEN FLOWER MARKET.

Many empty stands are seen in the market, and trade in all pot plants is very uncertain. Flowering plants of best quality make fair prices. I find Kalosanthes (Crassula coccinea) realise from 18s. to 24s. per dozen, but the hybrid varieties of this plant sell slowly and for much lower prices. Hydrangea paniculata, though very good in quality, does not clear well. Both white and yellow Marguerites are overplentiful. Plants of the later sown batches of Mignonette are now very good. Fuchsias are still procurable in well-flowered plants. Zonal Pelargoniums in all the more popular sorts are still plentiful. The Ivy-leaved varieties are not of first quality. Verbena Miss Willmott and other varieties have little demand. Lilium longiflorum are offered at low prices, but even at reduced figures stocks do not clear well. I noted good plants of Spiræa Silver Sheath; S. multiflora compacta is also good. Saxifraga pyramidalis is still seen, but supplies will not last much longer. Among Roses are some nice good H. P.'s. Best quality Ramblers are not quite so plentiful. Coleus have to be sold at very low prices. Lobelia is also cheap. Ferns are well supplied. I find some of the choice Davallias are offered at prices no higher than were formerly obtained for ordinary Ferns. Seedling Ferns of various sorts, in store boxes, can be had cheap. The best boxes of Pteris Wimsetti, P. cristata, P. tremula, &c., may be bought for about 18s. per dozen boxes. Palms do not sell readily, but I think there will be an advance in prices later on. A few growers still have ordinary bedding plants on hand, but there is now little trade in them.

CUT FLOWERS.

I found prices for best cut blooms were higher this morning. There was a decided advance in the price of Lilium and Eucharis, while Gardenias were not over plentiful. Supplies of best quality Sweet Peas were short, but there were plenty of second rate Roses from the open ground which are now abundant and cheap, but superior blooms are not plentiful. Gladiolus the Bride is making better prices. English Irises are plentiful. Spanish Irises are also seen, but they are almost over for the season. White Pinks, chiefly the variety Mrs. Sinkins, are very abundant. Supplies of Carnations of second quality are excessive. "Malmaisons" have not sold well this season, the long stemmed American varieties having largely supplanted them. Although, as a rule, most flowers may be procured in the market, I heard enquiries for Heuchera sanguinea this morning, and there were none to be found. Kalanchoe flammea plants were also wanted, but none were to be had. Hardy flowers do not now sell well. The principal trade is among best quality produce and good white flowers. *A. H., Covent Garden, Wednesday, July 4, 1906.*

CATALOGUES RECEIVED.

ENGLISH.

GEORGE BUNYARD & Co., Maidstone, Kent. Strawberries and other fruits; Dutch Bulbs and Carnations.

B. R. CANT & SONS, The Old Rose Nurseries, Colchester.—Cut Roses.

FOREIGN.

RIHACHIRO TASOI, Minamiyoshida-machi, Yokohama, Japan. Bulbs, Plants and Seeds, with several coloured illustrations.

M. HERB, Naples, Italy.—General collection of Bulbs and Seeds for autumn planting.

A. DESSERT, Chenonceaux (Indre-et-Loire), France.—Pæonies.

SCHEDULES RECEIVED.

ARBORICULTURAL HORTICULTURAL SOCIETY'S 20th Exhibition to be held in the grounds belonging to J. T. Morland, Esq., on Thursday, August 16, 1906.

CAMBRIDGESHIRE HORTICULTURAL SOCIETY'S Summer Flower Show on July 10, and Autumn Show on Wednesday and Thursday, November 14 and 15, 1906.

SOUTHERN COUNTIES 9TH ANNUAL CARNATION SHOW to be held under the auspices of the Southampton Royal Horticultural Society on the Royal Pier, Southampton, on Friday, July 20, 1906.

GARDENERS' DEBATING SOCIETIES.

KINGSTON GARDENERS'.—Through the kindness of Alfred Tate, Esq., a large number of the members of this society visited Downside, Leatherhead, on the 28th ult., to view the Rose garden. The weather was delightful, and the garden an object of beauty. There were both dwarf and standard Roses in masses, clusters of climbing varieties on arches and pillars. In every direction were seen Roses of every description, near the house is a fountain pond, in which is a fine collection of Nymphæas, at the time of the visit in charming bloom. The beautiful herbaceous borders, the well-kept trees and shrubs, together with the charming Surrey scenery, all tend to make Downside a most attractive garden. The great conservatory with its drapings of climbers—especially the variegated Cobæa scandens, the cool Ferneries, beyond, the Carnation houses, especially one long span-roofed structure, filled with "Malmaison" Carnations in bloom, all elicited the warmest praise. The improvements which have been effected at Downside during the past 10 or 12 years, are very remarkable. Mr. Tate is well supported by his able gardener, Mr. W. Mease. Under his guidance the party was hospitably entertained at tea, at the Home Farm.

LEO ERRERA.—A bust of the deceased Professor has been placed in the Botanical Institute of the University of Brussels, by Madame Errera. The ceremonial was attended by a large gathering of the botanists and physiologists of Belgium.

THE FRUIT CROPS IN IRELAND.—In the July number of *Irish Gardening* is a tabulated statement on the lines of the Fruit Report, published in our columns yearly, showing the prospects of the Fruit Crop in the sister isle. The outlook as a whole is very satisfactory, in spite of the bad weather experienced in April and May. Apples are recorded as 67 per cent. above the average. Pears and Plums are failures. Gooseberries are abundant in spite of the American mildew which is stated to be spreading. Currants, Raspberries and Strawberries are favourably reported on. Our own report, embracing the whole of Great Britain and Ireland, will probably be issued towards the end of the month.

THE WEATHER.

THE WEATHER IN WEST HERTS.

A record rainfall.—The past week was, on the whole, rather a cool one. One day was particularly cold for the end of June, and on the coldest night the thermometer exposed on the lawn fell to within 2 degrees of the freezing-point. The ground is now warmer than it has lately been, but is still only about 1 degree warmer than is seasonable, both at 1 and 2 feet deep. The most remarkable meteorological event of the week was the heavy rainfall on the night of June 28. The rain began to fall at 10 p.m., and continued without intermission until noon on the following day. During those fourteen hours over 2¼ inches of rain fell, which is not only the heaviest fall I have yet recorded here for twelve hours, but also for twenty-four hours, at any period of the year. Of the total amount, about one-third found its way through the percolation gauge on which short grass is growing, and exactly one-half through the bare soil gauge. Through the former gauge no rain at all had passed for nearly twelve weeks, while no measurable quantity had come through the bare soil gauge for over three weeks. The sun shone on an average for 6¾ hours a day, or for half an hour a day longer than is usual at this season. Calms and light airs prevailed, and on one day the average rate of movement at 30 feet above the ground was less than half a mile an hour. The mean amount of moisture in the air at three o'clock in the afternoon was 4 per cent less than is seasonable.

JUNE

An exceptionally calm and sunny month.—The days were as a rule warm, while most of the nights were, on the other hand, more or less unseasonably cold. In fact, during the first three weeks there did not occur a single night on which the temperature was in excess of the average. On the warmest day the highest reading was 78 degrees, a low extreme maximum for the month, and on the coldest night the exposed thermometer showed 4 degrees of frost—an unusually low reading for the time of year. Rain fell on only nine days, and yet to the aggregate depth of 3½ inches, which is 1¼ inches in excess of the June average—making this the wettest June here, with one exception, in the last twenty-seven years. It should, however, be explained that all but an inch of the total measurement fell in a single night quite at the end of the month—the latter being the heaviest fall experienced here in any one day at any period of the year during the past twenty-one years. The sun shone on an average for 7¾ hours a day, or for 1½ hours a day longer than usual. This was the calmest June I have yet recorded, the rate of movement in no hour exceeding twelve miles. The amount of moisture in the air at 3 p.m. fell short of the average by 4 per cent.—*E.M., Berkhamsted, July 4, 1906.*

ENQUIRIES AND REPLIES.

TO CLEAN MARBLE AND ALABASTER.—We have many marble vases on the terraces, and being near to a town they have become blackened with smoke. In order to cleanse them I have tried soft-soap and monkey-brand soap in hot water, but the result is not equal to the labour it entails. In the winter gardens we have art-craft specimens of figures in alabaster that have got rather dirty. Can anyone tell me how to clean these? *Hortus.*

MOTOR MOWERS (see also p. 415).—Ransome's 42 inch motor mower has, we believe, been used in the Royal Gardens, Kew, for four seasons. It has improved in its working every year, and is now a most serviceable machine and gives but little trouble, although further experience will, no doubt, suggest more improvements in the manufacture. It uses two gallons of petrol per day, and does about the work of one and a half horses. It is of no value where the ground is hilly, nor should it be used where the ground is uneven. For rough places it is not so good as the ordinary horse machine. The great thing is to get a man to understand it. At Kew an intelligent man was selected from the ordinary labour staff, and after a season's experience he understood the machine and its working almost as well as a mechanic. He now keeps it going without expert aid except, of course, when a breakage occurs. *J. W.*

LILIUM SUTCHUANENSE AND L. MAXIMOWICZII.—Under the above heading in the issue of the *Gardeners' Chronicle* for June 23, a correspondent asks for the distinguishing characters of Lilium Maximowiczii and L. Sutchuanense. Although these may not appear to be very different on paper, in the living plants there are so many differences that I should say it would be quite impossible for the cultivator to confuse them, either when he takes the bulb in his hand to pot or plant it out, or when he sees the growing plants from the time they appear above the soil till the stems wither. In point of growth the nearest ally to L. Sutchuanense is L. tenuifolium, but the former is much more vigorous. L. Maximowiczii is not nearly so elegant a plant in growth as L. Sutchuanense.

	L. MAXIMOWICZII.	L. SUTCHUANENSE.
Bulb.	Pale yellow, flattish round.	White, tinged with pink, more especially the outer scales, cone shaped, acute.
Stem.	Angular, smooth.	Cylindrical, densely pilose.
Leaves.	Comparatively sparse, sometimes ½-1 inch apart, lanceolate or linear-lanceolate. ⅜-½ inch wide, spreading, smooth, prominently 3 nerved.	Crowded, narrowly linear. ⅛-¼ inch wide, decurved, rough, margins scabrid, prominently 1 nerved.
Peduncles.	Sub-erect, 2-4 inches.	Horizontal spreading, 3-8 inches.
Flowers.	Orange suffused with red, pale orange reverse, black spots, at least half as large again as L. sutchuanense.	Bright scarlet, scarlet reverse, black spots, rarely wanting.
Habitat.	Native of Japan.	Native of the province of Szechuan, Western China, some 2,000 miles west of Japan. *O.*

ANSWERS TO CORRESPONDENTS.

EMPLOYMENT AT KEW: *J. D.* You should apply to the curator, Royal Botanic Gardens, Kew, for an application form. Candidates are required to have had at least five years' experience in practical gardening, and must be between the ages of 20 and 25 years.

GRAPE MRS. PINCE: *Ireland.* This variety requires to be artificially pollenated, owing to its shy setting qualities. When the bunches are in flower, a high atmospheric temperature should be maintained and it should not be allowed to fall below 70° at night time. Although, as a rule, there is plenty of pollen present, it is often ineffective, because the stigma is not receptive at the same time. The use of pollen from other varieties should, therefore be resorted to and applied for some time after the flowers have opened. Select for the purpose pollen from the freest setting kinds growing in the same house. The practice of drawing the hand or a camel's-hair brush over the bunch when the flowers are open is to be recommended among shy setting kinds.

IVY-LEAVED PELARGONIUM: *A. G. B.* We believe the injury is due to the punctures of mites which are invisible to the naked eye. Immerse the plants in tobacco-water. We have not seen the Heliotrope.

LABURNUM: *W. T.* L. vulgare var. involuta.

MANURE AND INSECTICIDE COMBINED: *H. B.* The manurial value should be great, judged by the smell. Use the substance with caution and ascertain its worth by experiment. Fumes from carbolic acid, as used for insecticide purposes, are not strong enough to kill ordinary plants. See Mr. Ward's article, p. 411. Woodlice are best trapped with pieces of carrots, potatos, cabbage leaves, &c.

NAMES OF FRUITS: *J. S.* A very nice fruit of Bellegarde.

NAMES OF PLANTS: *A. M., Derry.* Campanula glomerata. *J. McL.* Platystemon californicum. —*Rev. P.* 1, Buddleia globosa; 2, Cotoneaster microphylla.—*C. P.* Erigeron philadelphicum. *J. B.* 1, Clerodendrum foetidum; 2, Morina longifolia; 3, Anthericum ramosum; 4, Send when in flower; 5, Philadelphus microphyllus; 6, Cistus sp.; 7, Indigofera australis.—*J. P. S.* Probably Thlaspi arvense, but specimens shrivelled out of recognition.—*Zurich*: Anemone rivularis (Himalaya).—*H. J. D.* Arum Dracunculus.—*H. G.* 1, Hemerocallis flava; 2, Philadephus coronarius; 3, Spiræa opulifolia; 4, not recognised; 5, Rhododendron ferrugineum; 6, Cornus mas, variegated form.—*Peters*: 1, Læha purpurata; 2, Cattleya Mossiæ; 3, Miltonia spectabilis radians; 4 and 5, both Odontoglossum citrosmum; 6 and 7, Dendrobium atro-violaceum; 8, Dendrobium chrysotoxum; 9, Lycaste Rossiana.—*A. Y.* 1, Pleurothallis rubens; 2, Maxillaria tenuifolia; 3, Colax jugosus; 4, Masdevallia simula; 5, Ada aurantiaca; 6, Odontoglossum Lindleyanum.—*W. R.* 1, Tradescantia virginica; 2, Lilium Martagon.—*W. T.* Phacelia tanacetifolia.—*E. F. P.* 1, Phlomis fruticosa; 2, Spiræa Filipendula, double variety.

NECTARINES DISEASED: *W. C.* We gave an illustration of similar diseased fruits on p. 320 in our issue for May 19. It is a form of gumming, but what induces the formation and discharge of gum is not definitely known. From your remarks it would appear you have overcropped the tree also, which under any conditions is inadvisable. In the autumn fork a little lime into the surface of the ground over the roots, or apply a top dressing containing a considerable proportion of old mortar rubble.

PEACH SHOOTS DISEASED: *W. B.* The branches are attacked with a fungus, Botrytis, which commonly attacks imperfectly ripened wood or young shoots that have experienced a chill. All diseased parts should be cut off and burned, otherwise the disease will spread. After pruning spray the trees with a rose-red solution of permanganate of potash dissolved in water. The leaves also show traces of the "shot hole" fungus.

PEAS: *R. S.* You have not sent any roots, and on the haulm itself there are no signs whatever of disease. Can it be the effect of drought?

PLANE: *A. M.* The specimens are attacked by the "Plane leaf scorch" (*Gloeosporium nervisequum*). This disease is difficult to deal with, but the trees might be syringed with Bordeaux mixture in spring as an experiment.

SILVER LEAF DISEASE *Bathford.* The shoots are badly affected with this disease. We know of no cure for it, although sulphate of iron has been known to do good in some cases. The condition has been attributed by some authorities to a fungus at the roots, which may account for those trees which were heavily dressed with gas lime appearing most affected. If the gas-lime had injured the roots, fungus would more readily make its entry into the tissues.

SOUVENIR DE LA MALMAISON CARNATION: *F. W. T.* Layered plants occasionally fail just below the collar, owing to the cut portion commencing to decay. Excess of water, or the presence of wire-worms, fungus, or eel-worm may be the cause, but it is impossible to determine without having specimens before us.

THREAD-LIKE WORM: *G. I.* The worm is Gordius aquaticus—the popular name of which is Hair Eel. A notion still prevails in many parts of the country that it is nothing more than a horse-hair which has somehow acquired life by long immersion in water! When the pools in which Gordius lives are dried up, it becomes shrivelled and apparently lifeless, but revives on an application of water. They are not injurious to vegetation.

VIOLAS: *H. A. S.* You should have sent specimens, for without these it is impossible to determine what has caused the failure.

WISTARIA: *Wistaria.* Probably there have grown up some trees near to the house that cast a shade over the plant. We recommend you to withhold manure so long as the Wistaria continues to make sufficient growth, and if any is afforded it should be of phosphates and potash rather than nitrogenous. The more you can expose the shoots to the influence of sunshine the better will be the chances of a good display of flowers.

APPLE SCAB OR BLACK SPOT.

(CONIDIAL STAGE, *Fusicladium dendriticum* Fckl.)
(ASCIGEROUS STAGE, *Venturia Pomi* (Fr.) Wint.)

APPLE-GROWERS in Kent and Surrey have suffered within the last few years very considerable damage to their fruit through the attacks of a fungus which forms black spots on the ripe apple. The disease, which is known popularly as "Apple Scab," or "Black Spot," is caused by a minute fungus called Fusicladium dendriticum. Young Apples which are attacked by this fungus are either hindered in their growth and rendered more or less deformed, or the ripe Apple is found to be covered with blackish spots, due to the presence of the fungus, and the crop, in consequence, is rendered unsaleable, or its market value is much depreciated.

According to common report, the present disease is decidedly on the increase; varieties of Apples which, until lately, have been prized for their good growth and sound, clean fruit, are now beginning to be given up on account of their susceptibility to Apple Scab.

In consequence of reports received relating the damage caused by Apple Scab, visits were paid in the early spring of the present year to a number of plantations which during the past seasons suffered very considerable loss from this disease. I discovered that in these plantations the fungus was wintering over on the young wood of certain varieties of Apple.

The winter stage of the fungus causing Apple Scab is shown in the accompanying figures*. The young wood attacked by the fungus presents a blistered appearance, due to the presence of numerous blackish pustules of spores, which

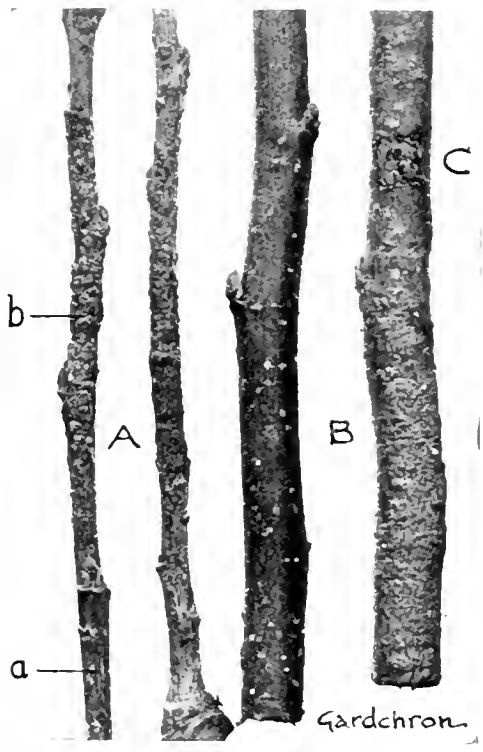

FIG. 9.

Apple Scab fungus on the young wood of Apple. A, On Cox's Orange Pippin; *a*, healthy wood; *b*, diseased wood, the blistered appearance being due to pustules of spores breaking through the bark. B, C, On Dumelow's Seedling or Wellington; B, healthy wood; C, twig with diseased patch below.

break out through the bark. The exact effect produced varies somewhat according to the variety of Apple attacked and the virulence of the disease. A diseased shoot of Cox's Orange Pippin is shown in fig. 9 (A); on the wood of this variety the fungus produces a conspicuous blistered appearance. In fig. 9 (B) the variety of Apple attacked is "Wellington"; here the evidence of disease is much slighter, the fungus breaking through the bark in small, inconspicuous, often scattered pustules. On "Lord Suffield," again, the effect produced on the wood may be very marked. I have seen cases with trees of this variety where the disease was of long standing, and little pruning had been done, where the shoots had become so full of the fungus that the bark was ruptured over comparatively large areas, and was beginning to peel off in flakes. Such affected areas are sometimes swollen and blistered, and then they superficially resemble those produced in the fungus disease known as "canker."

If one of the pustules of spores on an Apple twig affected by "scab" is cut across and examined under the microscope, we find the structure shown in fig. 10. Here we see some of the cells of the Apple twig shown at *a*; seated on these cells is a compact mass of fungus tissue, shown at *b*. This cushion-like mass of fungus spawn has pushed its way through the bark, which it eventually ruptured, and produced over its surface myriads of very minute brownish spores (*c*). Using a higher magnification, each spore is seen to have the shape shown in fig. 12 (2). These spores are capable of germinating immediately. In fig. 12 (2), below, spores which were taken from a diseased Apple twig in March are shown germinating after being kept for 24 hours in a hanging drop of water.

During the spring and early summer these spores are blown from the diseased wood on to the leaves and young fruit, and immediately infect them, producing the well-known "scab." Dark, olive-green patches, often somewhat velvety in appearance, are formed on the leaves; these patches often meet, and cover nearly the whole surface of the leaf, and in such cases a premature shedding of the leaves results. On the fruit the fungus forms conspicuous blackish spots, frequently circular in outline; in the case of badly-affected Apples the spots run together, and then cracks often occur, which cause the Apple to dry up. Apples affected with "scab" are not only ruined in appearance, but are affected injuriously as regards their keeping quality.

Although as a rule the Apple Scab fungus confines itself to the leaves and fruit, and is feared chiefly on account of the injury it does to the latter, I have seen cases where the young wood has been annually attacked so virulently that plantations have suffered damage to such an extent that the owner has been obliged to grub the trees; in these cases the variety attacked was "Lord Suffield."

Apple Scab as a disease of the fruit and leaves is comparatively well known as a fungus disease. The object of the present article is to point out that the wood of Apple trees is attacked by Apple Scab, and to familiarise growers with the appearance of such diseased wood, as in this country attention has not hitherto been directed to this point.

Now that the winter stage on the wood has been discovered, it must carefully be borne in mind that, in all probability, plantations which have suffered for several seasons from Apple Scab *are not necessarily free from the disease at any time of the year*, as the fungus will persist in its winter stage on the young wood of certain varieties of Apple in the plantation. In order to be able to take the fullest preventive measures (which are of the utmost importance in combating all fungus diseases), we must ascertain exactly what varieties of Apple are susceptible to

cut in pruning as much as possible of the diseased wood, and spraying the tree with a strong winter wash of copper sulphate, and again in spring with dilute Bordeaux mixture.

I have found Apple Scab on the wood of the following nine varieties:—Yellow Ingestre or Summer Pippin (very bad); Lord Suffield

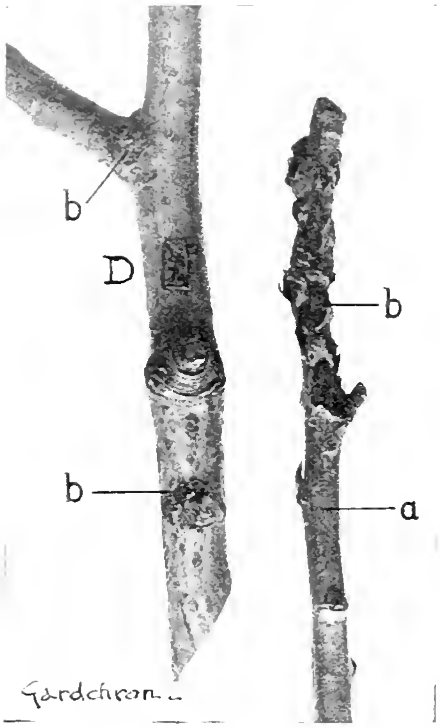

FIG. 11.

(very bad: in cases where the trees had been neglected, ruining the trees); Ecklinville Seedling (very bad); Cox's Orange Pippin (very bad); Wellington; Cox's Pomona; Warner's King; Mr. Gladstone; Councillor. The disease has been reported to me as seriously affecting the *fruit* of the following varieties:—King of the Pippins; Worcester Pearmain; Cox's Pomona; Lord Grosvenor; Suffield; Domino; Ecklinville Seedling; Loddington Seedling; Yellow Ingestre; Northern Greening; Wellington. The attacks of the Apple Scab on the above eleven varieties are frequently so severe as to quite ruin the market value of the fruit. The following seven varieties are also more or less susceptible:—Duchess' Favourite, or Duchess of Gloucester; Quarrenden; Allington Pippin; Bismarck (mainly on the leaves); Blenheim Orange; Warner's King; Cox's Orange.

The following nine varieties have so far stood out as resistant to the disease:—Beauty of Bath; Bramley's Seedling; Newton Wonder; Grenadier; Lord Derby; Lane's Prince Albert; Queen; The Victorian; Golden Spire.†

I should like here to draw the special attention of fruit-growers to the present disease, and to the necessity of their taking strenuous measures to prevent the enormous resulting loss which the disease occasions. Apple Scab is well known in the United States, where it has proved to be the most serious pest with which the Apple-grower has to contend. "Wherever Apples are grown they suffer more or less from this parasite. Some years the injury may be so slight that it is scarcely noticed, and during others it may attack a tree with such intensity that there is scarcely enough fruit or foliage left to tell the tale of the cause of the destruction. Apple-growers in western New York and in southern Michigan will bear evidence of the condition of orchards in the summer and autumn of 1892 and 1893. The trees appeared as if burnt by fire, and it was said that in some counties there was not produced one car-load of first-class fruit."‡

Numerous experiments dealing with this disease have been carried out on a large and commercial scale by many of the Agricultural Experiment Stations in the United States. Two facts stand out clearly as the result of the work done: first, that no other fungus disease annually ruins such a large percentage of the crop; and, secondly, that the disease can be effectually controlled by systematic spraying with dilute Bordeaux mixture (4 lbs. copper sulphate, 4 lbs. quicklime, 50 gall. water). The Bordeaux mixture should be applied as follows:—First spraying, on unfolding leaves before the blossoms open; second spraying, just after the petals fall; third spraying, two or three weeks later. (If an insecticide is wanted, add in the second and third sprayings Paris Green at the rate of 1 lb. of Paris Green to 200 gall. of Bordeaux mixture; or arsenate of lead can be added to the Bordeaux mixture at the same rate per gallon as when water is used. The lime in the Bordeaux mixture neutralises any excess of free arsenic, and so makes it an excellent medium for arsenical sprays, since it removes all liability of scalding the foliage).

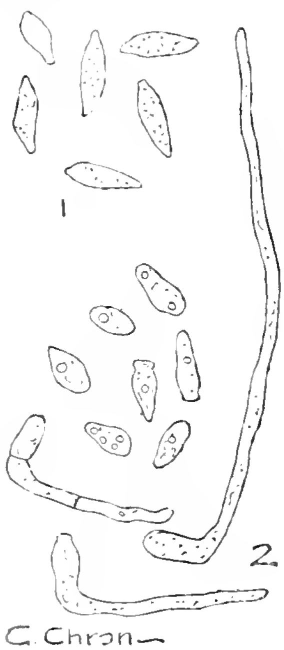

FIG. 12.
1. Spores of Pear Scab fungus; 2, spores [illegible] fungus, three spores [illegible] germinating [illegible]

If further (later) sprayings are necessary to save the fruit from "scab," it is not advisable to use Bordeaux mixture. Late sprayings may be made with the ammoniacal solution of copper carbonate.

When the Apple Scab fungus has attacked the wood it is most important that a strong winter wash should be applied when the tree is dormant. This wash may consist of copper sulphate alone (1 lb. of copper sulphate to 25 gall. of water).

The economic importance of now taking steps to prevent the further spread of the Apple Scab in our plantations may be realised from the fact that this very disease has been found to be so serious that in other countries legislation has been called in to protect the fruit-grower. Acts of Parliament in New Zealand (The Orchard and Garden Pests Act of 1903) and in Natal (The Plants Diseases Act, 1904) now enforce compulsory spraying of diseased trees, and also prohibit the importation of "scabby" Apples.

Since, at the present time, our Government gives no help in suppressing epidemic fungus diseases of cultivated plants, nor takes any steps towards preventing the importation of fresh diseases into our country,§ an imperative necessity exists for each individual fruit-grower to keep his plantations clean by frequent sprayings every year. The following fact is surely worth the serious attention of the Fruit-growers' Associations of this country. Apple Scab is causing thousands of pounds' worth of damage annually to our crops; foreign "scabby" Apples have a perfectly free entry into the country; while, if home-grown "scabby" Apples are attempted to be exported, they are refused admittance at the foreign docks.

PEAR SCAB.

(CONIDIAL STAGE, *Fusicladium pyrinum* (*Lib.*) *Fckl.*)
(ASCIGEROUS STAGE, *Venturia pyrina* (*Lib.*) *Aderh.*)

THE Pear Scab fungus is so similar to the Apple Scab fungus in general appearance and effect as scarcely to need a separate description. The spores are slightly different in shape from those found on the Apple, as may be seen by comparing fig. 12 (1) with fig. 12 (2). On Pear leaves the fungus produces the same velvety, dark, olive-green patches. "Scabby" Pears, however, crack, and become more deformed than "scabby" Apples. Young Pears are especially attacked; these soon fall off, or, if they mature, are usually worthless.

I have found Pear Scab more commonly present on the wood of affected trees than in the case of Apples; and here, again, the exact appearance of the diseased wood varies according to the variety of Pear attacked and the virulence of the disease. Sometimes the black pustules of spores are large and crowded, and quite conspicuous. These breaking through the bark of the young wood rupture it in a number of places, so that the diseased nature of the wood is very evident. This appearance is found on wood of the variety Doyenné du Comice when affected with Pear Scab (see fig. 11, to right). On certain other varieties the pustules are much smaller and cause much less evident ruptures of the bark, often far apart, and the disease is, consequently, far less conspicuous, as, for example, may occur in Pitmaston Duchess, a diseased twig of which is shown in fig. 11 (D). The general microscopical appearance of the diseased wood, with its pustules of spores, is the same as in Apple Scab (see fig. 10).

FIG. 13.—A PEAR FRUIT INJURED BY FUSICLADIUM DENDRITICUM.

† I should be very glad if readers of this journal would [illegible] notes on the behaviour in their neighbourhood of [illegible] varieties of Apples with regard to the Apple [illegible] of diseased wood on any other varieties [illegible]

‡ [illegible]eman. The Spraying of Plants, p. 245 (1903).

§ Two dangerous fungus diseases, affecting respectively the Gooseberry and Potato, have quite recently been imported, and are now widespread in our country.

I have seen wood badly affected with Pear Scab in the following varieties:—Doyenné du Comice (very bad); Marie Louise (very bad); Jargonelle (very bad); Beurré Diel; Beurré Bosc; Le Lectier; Doyenné Boussoch; Clapp's Favourite; Pitmaston Duchess; St. Germain.

It must be clearly understood that Pear trees, whose wood thus harbours the fungus through the winter months, will annually suffer from "scab" in the summer unless steps are taken to stop the disease. I have found constantly, in the case of Pear trees with affected wood, which have been kept under continuous observation through the spring, that the Pear Scab fungus spreads directly from the wood to the leaves as soon as they open, and to the young fruit as soon as it is formed.

The treatment for Pear Scab is exactly the same as for Apple Scab, viz., a winter spraying of the diseased wood with copper sulphate, and frequent spring and summer sprayings of the leaves and fruit, first with Bordeaux mixture and then with the ammoniacal solution of copper carbonate. *Ernest S. Salmon, South-Eastern Agricultural College, Wye, near Ashford, Kent.*

ORCHID NOTES AND GLEANINGS.

ERIA FLAVA.

An inflorescence of this singular and attractive species is sent by Sir Charles W. Strickland, Bart., Hildenley, Malton, Yorks, the possessor of many interesting Orchids and bulbous plants. Eria flava is an evergreen species, having ovate pseudo-bulbs bearing rather fleshy leaves. The inflorescence is 6 inches in length, and bears ten flowers each over an inch in width. The scape, ovaries and backs of the sepals are covered with white down. The sepals and petals are yellow. The lip is yellow with purple tinge on the raised or thickened parts. It is an intermediate-house plant, much more ornamental in appearance when not in flower than most of the other members of the genus, and when in bloom a very pretty species.

STANHOPEA TIGRINA.

THIS fine old species remains one of the most remarkable Orchids yet grown. A very fine variety of it is blooming in Miss Willmott's garden, Warley Place, Great Warley, Essex. The flowers, which are about 7 inches across, have the broadly ovate sepals of a deep claret purple colour, with a few pale yellow blotches near the base and apex. The smaller petals are yellow, heavily blotched with claret-purple, and the massive fleshy labellum is yellow at the base, with maroon blotches and white spotted with purple at the apex. It is native of Mexico, Guatemala, and some other parts of South America, and it thrives well in a basket suspended from the roof. An ordinary warm conservatory suits it admirably. The heavy pendent scapes bear three to four flowers each.

ONCIDIUM SARCODES ORNATUM.

A SPRAY of a very pretty and remarkable variety of Oncidium sarcodes is sent by the Hon. N. Charles Rothschild, Ashton Wold, Oundle (gr. Mr. J. T. Wells). It is one of several plants imported from Brazil, and similar in growth to the ordinary O. sarcodes, but differing very considerably in the colouring of the flowers, and especially in the front lobe of the lip, which is usually almost entirely yellow, being densely spotted with chestnut brown over the whole surface. The sepals and narrower petals are chestnut-brown margined with yellow, the lip yellow, with three large red-brown blotches in front of the purple-spotted crest, and smaller chestnut-brown blotches over the whole of the front lobe to the margin, which is bright yellow.

ONCIDIUM LIMMINGHEI.

ONE of the smallest of Oncidiums, with creeping habit, and with pseudo-bulbs and leaves resembling those of a miniature Oncidium Papilio, this pretty little species bears relatively large and showy flowers, borne on short, slender peduncles, each of which bears three or four flowers, which expand in succession. The flowers are an inch and a half across. The sepals and petals are reddish-brown with a yellow margin, the lip bright yellow spotted with red. The little plant presses closely to the block or raft on which it is grown. It is now a rare species, but it thrives well and flowers regularly with J. J. Neale, Esq., Lynwood, Penarth (gr. Mr. H. Haddon), who admires rare and curious Orchids, and is very successful in blooming reputedly difficult species.

IONOPSIS UTRICULARIOIDES.

A SPECIMEN of this pretty little species is sent by C. E. Franck, Esq., Yatton Hall, near Bristol, who collected it in Jamaica, together with several other interesting and rare species. It has linear, acuminate, fleshy leaves and slender panicles branched on the upper part and bearing numerous white flowers tinged with rose, the labellums, which constitute the prominent part of the flower, being veined with rose colour. The plant is dwarf, of tufted growth, and producing its elegant sprays of flowers freely, it forms a pretty object. The Ionopsis are Intermediate house plants, requiring to be grown on suspended blocks or rafts, but with little peat or sphagnum. *J. O'B.*

FLORISTS' FLOWERS.

SWEET PEA VARIETIES.

IN going over the trade trials of Sweet Peas last week, consisting of some 150 to 200 so-called varieties, the members of the Sweet Pea Society—amateur as well as trade—were all animated by the same wish, and that is that an early and complete expurgation from seed lists of all superseded varieties should be made. The trade complain of the need of still growing and listing so many comparatively indifferent varieties; the amateur growers assert that, owing to these huge lists, they are not helped to select only the best. Just as with Chrysanthemums, with the introduction of so many new varieties each year old ones go to the wall rapidly, and only a central, full, well-conducted, non-trade trial every year can satisfy the needs of the general grower. The trade trials were splendidly done, and rendered great service to those who inspected them, but they certainly did reveal most fully the grave need for a big purging of varieties. It is well to note that in looking over these trials, members of the Sweet Pea Society seemed to be concerned chiefly about form of flower and fitness for exhibition, about colour distinction or otherwise, and truth to assumed variety. But there seemed to be little regard shown for garden-decorative beauty, yet to myriads of private growers that is a matter of the first importance. Now and again varieties seemed to stand out markedly as very beautiful for garden effects. It was also felt, having in view the very inconstant character of many of the varieties seen, that it was both unsafe and unwise to make any awards to new ones until the constancy or otherwise of the stocks could be tested by growth. That fact, and the absolute need for a big clearance of all superseded varieties, seems to make an annual impartial trial by the society each year an absolute necessity. *A. D.*

KEW NOTES.

RARE PLANTS IN FLOWER.

CALCEOLARIA POLYRRHIZA.

THIS charming little plant, introduced from the Patagonian Andes some six years ago, has proved a most easy plant to manage, as well as being quite hardy. Either in a cool bay in the rock garden, where it has formed a tuft 2 feet in diameter, surmounted by its yellow flowers, or in an open situation among taller growing plants, it is quite at home. It is a spreading plant, and requires plenty of room.

CAMPANULA IMERETINA

Is a low-growing plant from the Caucasus, in the way of C. sibirica. It is said to grow naturally in the fissures of rocks, with branching stems, small leaves and violet blue flowers.

CAMPANULA RADDEANA.

This is also a native of the Caucasus, and seeds of it were received from the Tiflis Botanic Garden in the spring of 1905, along with those of the above species. They both flowered for the first time this year. C. Raddeana is a glabrous perennial of very distinct habit, growing about 1 foot high, with cordate leaves on long petioles. The flowers are large, and in colour like those of C. pulla.

C. PHYCTIDOCALYX.

This Armenian plant, which is also known under the name of C. amabilis, is also in flower. It is a somewhat disappointing plant at Kew, where it forms large tufts of deep green foliage, but produces very few flowering stems. It is intermediate in habit between C. Steveni and C. persicifolia.

C. SULPHUREA.

This interesting little annual from Palestine and Egypt is remarkable for its unique colouring among plants of this genus. Although its habit is not good, it is worth growing for its pale yellow colour alone, but it requires to be treated as a half-hardy annual. Planted out thickly in groups, it is effective enough, but, unfortunately, it does not set seed freely in this country, except in very favourable situations.

EPILOBIUM LUTEUM.

Although not a new species, this is still rare in gardens. It is, however, a choice plant of compact habit, growing about 1 foot high, and bearing a long succession of pale yellow flowers all through the month of June. A native of North-Western America, it does not seed about like most other members of this family, but increases slowly by means of underground stems. It is a good companion for the rosy-purple E. obcordata from the Rocky Mountains.

MECONOPSIS HETEROPHYLLA.

This charming annual is the sole representative of this genus in America, and was figured in the *Gardeners' Chronicle*, 1901, xxix., p. 413. It was introduced from California by Kew in 1899, and flowered that same year, being figured in the *Botanical Magazine*, t. 7635. About 18 inches high, with pinnatifid leaves of a succulent nature, the orange red flowers have a deep maroon centre, making it a most attractive plant. It produces seeds freely, and they come up readily when sown in the open border.

[illegible]

Is a new plant from Asia Minor, with white woolly leaves like those of some of the species of Phlomis, and stems about 1 foot high, bearing whorls of sulphur-yellow flowers. It grows in Alpine regions in stony soil at an elevation of 6,000 to 7,000 feet, and is quite hardy in this country in a well-drained warm situation.

Among other interesting plants in flower is a group of Dracunculus vulgaris in the Fern border, with its large handsome foliage and numerous chocolate-coloured spathes. *W. I., July 5.*

IRIS TINGITANA.

THIS is a very lovely Iris, its flowers being quite twice the size of those of the Spanish Iris, to which it is allied. The colouring is delightful, the standards being violet-blue and the falls a delicate French-grey, set off by the glowing yellow of the central blotch. Though introduced from Tangiers in 1872, and, therefore, fairly common, few growers are apparently able to flower it satisfactorily. Ever since its introduction letters have periodically appeared in the gardening Press lamenting its refusal to bloom. This ill-success has not been confined to amateurs who have recently made gardening their hobby, but many whose names are household words in the gardening world have also had to admit failure. Sir Michael Foster, writing a few years ago, stated that it had not flowered with him in the open, the late Rev. C. Wolley-Dod wrote that he had grown it 20 years without having flowered it, and the late Rev. Henry Ewbank recounted that for 15 years it had not bloomed with him, while Mr. Archer-Hind informed me that he had had it for 30 years and had only flowered it once, and Mr. Irwin Lynch, in his Book of the Iris, states that it is not worth general cultivation, presumably on account of its shy flowering. In the face of all these recorded failures it is pleasant to be able to chronicle a success, to which I think the accompanying illustration fully testifies. Out of 30 bulbs planted early last November, 29 threw up flower-spikes. The first flower opened at the end of February, more during March, and the majority early in April. The photograph was taken in the second week of April. I have now flowered this Iris for four years and should be very sorry to be without it, as a colony in full bloom is a beautiful sight and at the time quite the glory of the garden. In the neighbourhood of Penzance I have seen Iris tingitana flowering well, though I know several Cornish gardens where it blooms infrequently and I have never before met with it blooming as profusely as shown in the illustration. *S. H. Fitzherbert.*

THE ROSARY.

ROSES AT THE REGENT'S PARK SHOW.

THE following remarks are supplementary to the report published in the last issue of the *Gardeners' Chronicle* of the show held at the Royal Botanic Gardens on July 5. Statements, by those supposed to be capable of forming opinions on the prospects of this season's Roses, were rife as to the injury caused to the plants by late spring frosts; still, there were but few poor or disfigured flowers visible, the general good quality and perfection of form being remarkable. Where injury was most apparent was amongst blooms which came from highly-favoured Devonshire. In some districts flowering has been much retarded by cold weather in what is regarded as early summer, viz., the month of May, although, according to the astronomer, that season is not due till "midsummer day." In Sussex, as a nurseryman told us, they had had the severe infliction of eleven successive frosty nights in the month named, which had so retarded the blossoming of his Roses that none was in bloom at the date of the show, and the earliest were sure to show much disfigurement, although Nature would, he thought, compensate the cultivator by an abundant harvest of fine blooms a little later. It was hard to realise that such conditions had prevailed, on looking around the marquees and noting the galaxy of floral beauty in hybrid Teas, hybrid Perpetuals, and the so-called "garden Roses," which were piled up in such profusion on every side.

Everyone is on the alert on these occasions to inspect the new varieties that the rosarian hybridists vouchsafe. This year these were few, and not particularly beautiful. They sprang in every instance, in so far as regarded the premiated varieties, from the hybrid Tea class, either wholly or on one side or the other. Gold medals were awarded to the varieties William Shean and Mrs. Peter Blair, shown by the raisers, Messrs. Alexander Dickson and Sons, of Newtownards, Co. Down, Dublin, and Belfast, who raised Mrs. R. G. Sharman Crawford, Earl Dufferin, Mrs. W. J. Grant, and other fine Roses. The first-named is of a bright rose-pink tint, having fairly numerous petals, but withal a rather loosely-formed flower; and the second is of a pale yellow tint, with short, almost orbicular, petals. Another new variety, shown by Mr. S. Bide, nurseryman at Guildford and Aldershot, and named Queen of Spain, was awarded a certificate of merit. It has a compact form, especially beautiful when half expanded, when it seems to be the most perfect. The colour is a delicate flesh-pink. Mrs. Dorothy Robins is another new Rose—an immense flower, pink in colour, and with numerous petals; but this variety and Madame Constant, shown by that veteran rosarian Mr. G. Prince, were passed over by the judges.

The Roses which were shown by Messrs. B. R. Cant & Sons, and were awarded the premier prize in the nurserymen's champion competition for best 72 blooms, constituted an extremely fine lot, and displayed most vivid tints in the varieties C. J. Grahame, Duke of Wellington, Etienne Levet, A. Colomb, and Capt. Hayward.

The best light coloured varieties were the unapproachable Bessie Brown and Killarney. The winners of the second place, Messrs. D. Prior & Son, had many remarkably fine flowers, but the quality was unequal, although the blooms of E. Levet, Mrs. John Laing, and Ulrich Brunner would have satisfied the most exacting of judges.

The bulk of the prizes in the bigger classes were secured by the two firms of F. Cant & Co. and B. R. Cant & Sons, the magnificent blooms of Ulrich Brunner, Dupuy Jamain, and Horace Vernet having the pride of place in the winning stand of 40 triplets, shown by Messrs. B. R. Cant & Sons; and equally fine, in light coloured varieties, were White Lady, Frau K. Druschki, Mrs. J. Laing, Alice Lindsell, François Michelon, and Souvenir

FIG. 14.—IRIS TINGITANA.

d'Elise Vardon,. Messrs. F. Cant's flowers of Oberhofgartner Terke, Ulster, Lady Mary Fitzwilliam, and Mildred Grant were magnificent, and hardly less so were Aimée Cochet, Gustave Piganneau, and Dr. Andry. Messrs. Prior's stand showed many grand blooms. In the twenty triplet class Mr. G. Mount, the Canterbury grower, had very fresh-looking blooms, compact, and of fine substance. Messrs. C. & W. H. Burch, of Peterborough, and Cooling & Son, of Bath, exhibited creditable blooms, the varieties Gladys Harkness, J. Ruskin, J. Stuart Mill, and Mrs. John Laing being very superior. This was a class in which the competition was exceedingly strong. Excellent blooms in the twenty-four class came from Mr. C. Turner, of Slough.

Teas and Noisette Roses seemed to be scarcely in the best condition; still, the winning boxes, those of B. R. Cant & Sons, contained several gems in Mrs. Ed. Mawley, Marechal Niel, Souvenir d'Elise Vardon, and Golden Gate, a creamy white bloom tinted with pink, and of a globular shape.

Shown in bamboo stands, there were noticeable blooms of Augustine Guinnoiseau, L'Ideal, W. Allen Richardson, and Gardenia. These were shown by Mr. H. R. Darlington, an amateur.

The champion trophy, of the value of 50 guineas, given to the amateur who shows three six blooms distinct varieties, was awarded to Mr. E. B. Lindsell, the exhibit consisting of magnificent flowers.

Decorative Roses formed a large section of the exhibition, and in the nurserymen's section Mr. G. Mount distinguished himself, showing Papillon, Abel Chatenay, Gustave Regis, Marquis of Salisbury, and Electra; and Messrs. C. Prince and J. Mattock showed a capital lot of sprays, especially the last-named nurseryman, Madame Ravary, Lady Battersea, and Queen Alexandra being the better varieties.

No Rose show is complete nowadays without table decorations in Roses, and most of those observed were pleasing in design and materials, although, as we think, not sufficiently raised to allow of a clear view of one's *vis-a-vis*. The prettiest consisted of the climbing, single-flowered variety Mrs. O. G. Orpen (blush Rambler), the blooms having a width of 4 inches, and the buds exquisitely formed.

Miss J. B. Langton had a device of a central bowl, and small vases around it filled with the lovely Rosa macrantha.

Pyramids of Roses in bunches erected on tables 6 feet square showed off the "garden Roses" most effectively, admitting of their close inspection by the visitors. In this competition the leading exhibitors were Messrs. Paul & Son, F. Cant and Co., C. Turner, and G. Cooling & Sons. Baskets of Roses were very nice and showed great fertility in design; and a bowl shown by Mrs. O. G. Orpen, and filled with blooms of the white damask Lady Sarah Wilson, a crimson coloured variety, was awarded first prize and a piece of plate. Fine blooms were observed in the smaller competitions of Mad. Gabrielle Luizette, Mildred Grant, Florence Pemberton, Catherine Mount (a delicate flesh-coloured Rose), the pale yellow Medea, Duchess of Portland, Caroline Testout and Albert Grant.

The show was honoured by the presence of her Majesty Queen Alexandra, who showed much interest in the exhibits, and stayed an hour in the marquees.

The visitors were very numerous at one time during the afternoon, and the air in the marquees excessively warm, in spite of the abundant sprinkling of the roofs with water. The gardens of the R.B.S., now looking their best, afforded a pleasant retreat for the visitors. *Z.*

RUBUS "LUCRETIA."

MESSRS. R. VEITCH & SON, of Exeter, send us specimens of this bramble which was obtained from Holland some few years since but without any history. It has since been found to be a most useful plant in many ways, and from the fact of its producing an abundance of large white flowers, equal in size to those of R. deliciosus, it is a fitting subject for either pillars, pagodas, sloping banks or rocks. The fruits, which are large and black, ripen quite a fortnight earlier than those of the ordinary Blackberry, and are of a delicious sharp flavour and useful for cooking purposes.

FIG. 15.—RUBUS LUCRETIA.

ASTILBE ASTILBOIDES.

WRITING in the *Gardeners' Chronicle*, September, 1895, p. 359, Mons. E. Lemoine was the first to point out that the plant so widely known as Spiræa astilboides is not a Spiræa at all, but a true Astilbe. He gives a brief description of the plant, and says:—"Maximowicz, who discovered it in Japan, separated it from Spiræa, and called it Aruncus astilboides. But the species of Aruncus cannot be separated from Spiræas, and all the characteristics of the plant we allude to indicate that it is Astilbe or Hoteia. So, keeping the specific name—now, perhaps, too widely spread to be changed—it should be named Astilbe astilboides." In a footnote to the same article Lemoine adds:—"Our trials at fertilising A. astilboides var. floribunda with S. Aruncus have always been ineffectual, another reason for separating this plant from the Spiræas and rejecting the classification of Maximowicz."

Recently, working at Astilbe, I had the opportunity of examining the type-specimen preserved in the Kew Herbarium, together with living material, and I came to the conclusion that there can be no doubt but that Lemoine is right. He is wrong, however, in attributing the error to Maximowicz. Briefly, the history of the subject is this:—On June 4th, 1879, Mr. William Bull, of Chelsea, sent to Kew for name a plant which he regarded as a new species of Spiræa, he having received it from Japan. If it turned out to be new, he suggested that it might be called Spiræa nivosa, a provisional name under which he had exhibited the plant. This plant of Bull's was erroneously identified with Spiræa Aruncus var. astilboides of Maximowicz. Here the unfortunate mistake originated. Why the two plants should have been confused is not easy to understand. Three specimens of Maximowicz's plant are preserved in the Kew Herbarium, having been received from St. Petersburg in 1872. One of these specimens is in fruit, the others in flower. In all three the structure of the flowers is essentially that of Spiræa Aruncus. Bull's plant, on the other hand, is in structure essentially a true Astilbe.

Several species of Astilbe are known from Japan, but the Kew Herbarium does not possess any wild specimens of Astilbe astilboides, and I can find no record of any such having yet been discovered. This is remarkable, nevertheless, A. astilboides is very distinct from any other species of Astilbe known.

Mons. Lemoine here points out the absurdity of the name "Astilbe astilboides," but, whilst suggesting A. aruncoides as a more suitable name, remarks that the name is not more absurd than many others in use. Personally I have the gardener's dislike to changing well-established names if in any way avoidable, and, as a mere name "astilboides" will, I think, do as well as any other. It would possibly prevent confusion in the future if an entirely new name were given to this plant, but cultivators, at any rate, would not appreciate such a change. The following is the synonymy:—

ASTILBE ASTILBOIDES.—Lemoine, in *Gardeners' Chronicle*, September, 1895, p. 359.

Spiræa Astilboides.—T. Moore, in *Gardeners' Chronicle*, Dec. 1880, p. 113, with figure.

Spiræa Aruncus, VAR. *Astilboides*.—Hort. Kew non Maximowicz.

E. H. W.

AUSTRALIAN RUST FUNGI.

WE have just read with considerable interest and pleasure the latest contribution to the literature of the "rust fungi," called "The Rusts of Australia: their Structure, Nature, and Classification," by D. McAlpine, Government Vegetable Pathologist. It is a portly royal octavo volume of 350 pages, illustrated by 60 plates, including 366 figures. It is published in Melbourne, but we regret that the name of no London publisher appears on the title page, since there must be many mycologists in this country who would be glad to possess themselves of this volume, which is a clear epitome of all that is known, and suspected, of the "rust fungi" up to date. It is very satisfactory to see that the various views, sometimes conflicting, of different authors are scrupulously credited to their source, and, by an ingenious method, the reference is given in full to each quotation.

The work is divided into two parts, the first: "General characters and mode of life," in nineteen chapters; and the second part: "Classification and technical descriptions," with glossary and copious indices. Of the plates ten are in colours, the residue from photomicrographs.

We note with satisfaction that the explanations are as little technical as possible, and that the volume is calculated to meet the requirements of the most elementary, as well as of the most advanced, student.

We cannot give extended extracts from the work, but we have noted some few short ones for

tions which deserve to be borne in mind, as they are many of them suggestive.

"The vegetative reproduction through a perennial mycelium is not always easy to prove, but its importance cannot be overrated, for hidden in the tissues of the plant it cannot be reached by the ordinary means for controlling the growth and spread of fungi, but involves the destruction of the plant, or at least of those parts which harbour it. As Australian examples, we may note Uromyces trifolii, which attacks the white clover, and Phragmidium subcorticatum, or rose rust, in which the mycelium of the æcidial stage penetrates all the tissues, and in each succeeding year forms a new layer beneath the old." (P. 5.)

"The indirect relation of water, or the effect of soil moisture, which acts upon the parasite through its host, has also been studied and shown to be of great importance. An abundance of soil moisture at the growing season, in the case of Asparagus rust in California, is stated to increase the vigour and vitality of the host, and retard the development of the fungus." (P. 10.)

"Arthur comes to the conclusion that the æcidium, with its accompanying spermogonia, represents the original sexual stage of the fungus, and that it still retains much of its invigorating power." (P. 17.)

"It is interesting to notice that in some cases the uredospores may be produced, not only at the surface, but within the tissues. This happened with Puccinia pruni, in a Peach fruit, where spore-beds of rust freely producing uredospores were imbedded in the tissue, in more or less rounded cavities, up to 5mm. below the surface. The decaying fruit would form a splendid matrix for preserving the spores till next season." (P. 19.)

"The germination of the teleutospores of Puccinia graminis in Australia was tested under different conditions. Badly rusted straw was placed in the cool stores for three months, one portion being kept at a temperature of 4° C., and another at 18° C. A third portion of the same straw was simply kept in the open, and when tested for germination in the spring, only the spores exposed to the weather germinated." (P. 24.)

"It may be well to bear in mind that in no country in the world probably does Puccinia graminis cause as great injury to wheat as it does in Australia, a country where barberries are practically non-existent, and in which the æcidial stage has never been found." (P. 58.)

"Kirk informs me by letter that barberries are being largely used in New Zealand for hedges, but, up to the present, I have never seen any sign of æcidia of P. graminis on them, although I have examined hundreds." (P. 74.)

"Hennings has recently made observations which tend to show that plants previously susceptible to the attacks of a parasitic fungus may gradually become immune when they are changed to rich ground where they are better nourished and more vigorous." (P. 60.)

The above must suffice for our purpose, but there is one other, which is more personal.

"In Cooke's Handbook, published in 1892, there are only 72 recorded"; and again, "The Australian rusts recorded in the Handbook published in 1892 were 72, but the number now has reached 161." Nevertheless, he admits that "When one considers that the material had to be sent such long distances (thousands of miles), and often limited in quantity, as well as imperfectly preserved, it is surprising the number of rusts recorded, and the general accuracy of the descriptions."

In local lists we have observed that a great and rapid increase in the number of species recorded is not always evidence of progress, and may be open to suspicion. We remember some twenty years ago the process of "splitting" was applied to phanerogamic plants to an alarming extent. More recently some such process has become apparent in fungi. It is so easily done, but always has the odour of a quack medicine. Such old species as Puccinia compositarum or Puccinia umbelliferarum afford admirable facilities for the multiplication of species. It is a suggestion worthy of consideration whether local lists could not be very rapidly extended if it were feasible to constitute a new species, amongst the Uredines, for every separate host plant.

We observe also that our author has not yet purged himself of the opinion that the intermediate form of spore, or mesospore as we have called it, in Puccinia pruni, is really only the true uredospore seen obliquely, or topsy-turvy. How true it is that

"Faith, fanatic faith, once wedded fast
To some dear falsehood, hugs it to the last."

In order to justify this contention, it may be noted that our author has modified, or "amended," the diagnosis of the uredospore from the original three or four lines to double that number. The process of "amending" a diagnosis, in order to bridge over a difficulty, has always been received with more of condemnation than commendation, and, if sometimes convenient, it is never scientific. *M. C. C.*

NECESSARY PLANT FOOD CONSTITUENTS.

SOME recent investigations by Mr. Albert F. Woods, of the Bureau of Plant Industry, United States, have indicated that the element potash is necessary to the water pressure in plant-cells. This condition is one of the most important physical requirements of plant-growth. The fact that potash increases water pressure in cells would also indicate that it increases the water-absorbing power of the plant as a whole, thereby increasing its ability to hold more effectually in times of drought the water which it has absorbed.

Potash also increases the water-holding power of soils for the same reason, and is, therefore, most valuable from this standpoint on all sandy, porous soils. On the other hand, potash must be used with discretion on soils naturally heavy and wet, as it tends to cement the particles of soil together into hard lumps during very hot and dry weather.

Experiments have shown that a manuring of potash salts enables outdoor herbaceous plants to resist light frosts, probably by increasing the water-holding power of the plant-cells to which we have already referred, thus preventing an excessive withdrawal of the water from their tissues.

POTASH ESSENTIAL FOR MATURATION.

A supply of potash in the soil hastens and perfects the maturation of plants. When in combination with phosphoric acid, the wood of fruit and other trees in particular is solidified, thus enabling them to better withstand severe winter cold. Potash is extremely essential in fruit-bud formation. Professor Webber has stated that a lack of potash causes in the Orange tree an excessive growth of weak, immature wood, which does not harden up as winter approaches, and is liable to be injured by frost.

It is further possible that potash may have an influence on the intensity of colour in flowers and fruits, especially where the intensity depends on the amount of acid present in the cell sap. The importance of varying tones of colour is well understood by florists, and the ability to slightly change a shade by the use of chemical fertilisers would be valuable not only to florists, but to fruit growers and other horticulturists. The whole question should receive careful investigation by those capable of conducting such work.

POTASH IN SOILS.

Clay soils, and particularly clay loams, usually contain about six-tenths of one per cent. of potash; lighter loams about three-tenths of one per cent.; while exclusively sandy soils contain less than one-tenth of a per cent., but even this small amount is equivalent to 3,500lb. of potash per acre, assuming that an acre of land one foot deep weighs 3,500,000lb.

As a rule, therefore, it is only upon the exclusively sandy soils that a lack of potash may be expected. And yet it is found at Rothamsted, that with a potash content of 36,000lb. per acre in the top 9 inches of soil, the growing plants are unable to procure sufficient for their needs. The greater part is locked up in an inert condition, so that the addition of a few hundredweights of sulphate of potash in the soluble form, makes all the difference between a full or partial crop.

POTASH AS MANURE.

In the use of potash manures, careful attention should be given to their composition. Muriate, also called chloride of potash, kainit salt, and sulphate of potash are examples of the common potash fertilisers in use. The two former are, as a rule, cheaper, and especially the kainit, and for some crops just as good as the sulphate, and should, therefore, in these cases be used. The sulphate is preferable for certain crops, and when doubt exists as to a full supply of available lime in the soil, sulphate of potash is much safer and more satisfactory.

GARDEN FLOWERS.

A loose, warm soil, rich in humus, is the first requisite for a healthy growth, a luxuriant development, and for a plentiful inflorescence of all kinds of garden flowers. But the physical condition of the soil is only one of the needful factors for successful production; the other is a vigorous and plentiful nutrition of the crops.

Plants not only differ in their power of acquiring food, but certain plants are able, because of their peculiar root system, or period of growth, to appropriate food more readily from insoluble sources than others.

Nitrogen, phosphoric acid, and potash are seldom or never present in the same variety or species of plants in the same proportions when grown in different localities. They associate themselves in the living organism not only by chemical affinities, but they are governed by many agencies, as hereditary forces in the plant, moisture, sunlight, heat and cold, presence or absence of an abundance of plant-food, and the ease or difficulty of securing it.

At the same time, analyses of soils and plants answer questions which could not be obtained in any other way, and usually indicate the direction which should be taken to reach the most satisfactory results.

In regard to the production of garden-flowers, we find, as a rule, that phosphoric acid is a much more important constituent than it is in the growth of kitchen vegetables.

The following table gives the proportion of phosphoric acid and of potash in the ashes of ten selected species of flowers, as analysed and recorded by Dr. A. B. Griffiths:—

Description of Flower.	Phosphoric Acid, per cent.	Potash, per cent.
Veronicas	34.3	30.3
Lupines	39.2	22.0
Martynias	32.3	26.2
Salpiglossis	26.3	26.1
Verbenas	42.7	28.2
Daturas	34.7	20.2
Echeverias	32.1	26.9
Godetias	23.1	30.1
Auriculas	33.9	16.6
Gladiolus	28.2	18.9
Mean	33.7	24.6

The data show us that the average amount of phosphoric acid in the ashes of these ten species of flowers is 33.7 per cent., equal to one-third of the whole of the constituents; while the potash forms but 24.6 per cent., rather less than a quarter of the whole weight of the mineral

elements. In the case of kitchen vegetables, these proportions are reversed. This indicates the importance of a full supply of phosphoric acid in the soil if satisfactory flowering plants are to be raised.

FUNCTIONS OF PHOSPHORIC ACID IN PLANT GROWTH.

We find that the element phosphoric acid enters largely into the nutrition of the nucleus of all plant cells, and it is important to remember that the nucleus is the most highly specialised portion of every living cell, and is its controlling centre. In the absence of phosphoric acid, the nucleus can neither grow nor divide for the production of new cells, and the growth of the plant comes, therefore, to a standstill.

Phosphoric acid is also an important constituent of the green chlorophyll bodies. The formation of sugar and starch from the carbonic acid of the air can be accomplished by plants only when the chlorophyllous matters are present. Thus the reduction of phosphoric acid in the soil below a certain amount, besides preventing growth, causes a yellowing of the foliage. Some Orange growers claim to be able to recognise phosphate starvation by the appearance of the young leaves. If these, when they first push out, or while they are still young and tender, present a slightly variegated appearance, mottled with light and dark green, it is claimed that they are suffering from a lack of phosphoric acid, and that if a liberal application of superphosphate, basic slag, or bone meal is applied, this appearance may be checked.

A similar mottling of the leaves of garden plants cannot always be cured by the addition of phosphates alone, it is necessary that potash be also added.

Yellowing of foliage due to the lack of iron in the soil usually shows itself first in the young leaf buds, while the older leaves may retain for a long time their normal green colour.

A lack of nitrogen in the soil is usually indicated by much the same symptoms as are produced by a lack of phosphoric acid and iron. *J. J. Willis, Harpenden.*

FERN CRESTS.

Even the most casual observer at our exhibitions of flowers and foliage plants must have noted how large a proportion of the Ferns exhibited display tassels on the tips, while nothing of the sort is ever seen in the not infrequently very similar leaves of other plants. The production of these tassels is indeed a very peculiar feature, so many widely diverse species of Ferns having developed them in their varietal forms, and in our native species not only have the large majority of them varied in this way, but a number have done so repeatedly and on very different lines. The tassels are produced by the midribs or midveins of the frond or its subdivisions splitting up, or rather branching into a number of minor ones, each of which carries a leafy extension with it, and, in this way, forms a bunchy or fan-like termination instead of a pointed one. This may be explained thus: each sub-division ordinarily is built up by cells, which multiply at the tip, where there is always one mother-cell, the base of which divides and sub-divides and builds up the division as it proceeds. With the tasselled forms this mother-cell appears to divide not merely from the base, but also to split up terminally into other mother-cells, each one of which then proceeds to do its best to build up an independent division on its own account; result, a bunch. Leaves of flowering plants grow on a different plan, and cannot, therefore, become tasselled in the same way, though we have a sort of imitation of it in the Celosias and other fasciated plants, but in these a number of growing points are really engendered embryonically, and their resulting growths become eventually massed together for lack of room, while a Fern tassel only begins at its own base and then radiates freely—a fundamental difference. The degree to which this tasselling is carried varies indefinitely. It appears frequently in what may be termed an accidental form in the shape of duplicated or partly-duplicated fronds, where the midrib has split into two branches, each then producing divisions on both sides. There is, however, no permanence in these "accidentals"; the rest of the fronds are normal, and the spore produce normal. The common Hartstongue is very apt to vary in this minor way, by producing forked tips, and a quite common form, "lobatum," has the frond tip multiplied into several and in a constant form; we usually come across several of these in a day's hunting. It is, however, in the divided Ferns, such as the Lady Ferns, Male Ferns, Shield Ferns, that we find this capacity for tasselling or cresting most highly developed. In the finest crested wild "sport" of the Lady Fern (*A. ff. cristatum* Kilrushi, which fell to the writer's lot in an Irish ditch, the tassels on the pinnæ or side divisions are very long, and so much sub-divided into minor strands that, by actually counting, there are innumerable divisions* in one tassel, while the huge bunch-tassel at the frond tip is also beyond counting. In this, as is usual with thoroughbreds, the pinnules, or secondary divisions, are also tasselled. In wild finds this is as far as cresting goes, but in one of the higher developed selected forms, *A. f. f. percristatum superbum*, it goes a step farther, for the pinnulets or divisions of the pinnules are dilated into tiny tassels. As all this occurs on perfectly symmetrical lines, we have the curious fact that at definite specified stages all over the frond and at many hundreds of points, every mother or terminal cell alters its plan of construction and breaks up into others to form a tassel instead of a point. This is characteristic of all crested forms proper, but in many varieties there occurs instead an irregular branching, resulting in repeatedly forked fronds varying from simple forked tips or twin fronds joined at the base to fronds which branch over and over again: in extreme forms of this kind the flat frond formation disappears entirely and the Fern becomes a bunch of ramifications. *Scolopendrium v. densum* Kelway, a diminutive Hartstongue, and *A. f.f. unco-glomeratum*, a Lady Fern, have become in this way like balls of delicate moss, with nothing truly Fern-like about them. The character of tasselling proper also varies greatly. Thus a tassel may be formed by one simultaneous division into many pointed tips without re-division (polydactylous or multiceps), the result being a flat radiation, or the divisions may split up again and again in radiating lines forming a compact fan. Both these types of division may also radiate like the tip of a lightning conductor, so as to form bunches (corymbiferous). As a rule such tassels are seen to be practically complete when the frond tips uncoil and only expand subsequently; but, in other cases, the frond and its divisions may unfold without tassels, the tips presenting merely a woolly appearance, which subsequently grows out into, it may be, crests of considerable expansion. We have, indeed, seen a crest as large as a cricket ball developed on a form of Pteris serrulata (Appleby ana) from a single point by continuous growth, and forking and re-forking almost ad infinitum, the tips being apparently unable to close, as it were, the circuits of growth. Naturally, also, the character of the tassels corresponds with the frond type, a lax frond having lax terminals, and dense, congested ones, equally compact crests. As a rule, too, the divisions of a frond are really miniatures of itself, so that a frond with a large terminal tassel will bear well-tasselled pinnæ, and probably traces of cresting in the pinnules, but there are a few instances where the pinnæ, and even the pinnule, are tasselled and the frond tip pointed or only slightly tasselled, and converse cases of large terminal tassel and pointed side divisions. A curious fact in connection with crested Ferns is that although extra leafiness, i.e., abnormal expansion of the frond forming what are known as the plumose or feathery section of varieties, is accompanied by a decrease in the production of spores, the production of even abundant crests has no such effect, the crests themselves producing spores copiously. These spores, too, as a rule, reproduce the crested type, though frequently on a variable scale, i.e., more or less developed, and it is due to this fact that the Fern selective cultivator has been able to raise varieties in which the cresting is even more developed than in the best wild finds. *Chas. T. Druery, V.M.H., F.L.S.*

[The repeated sub-division of the frond so remarkable in Ferns, and doubtless connected with the forked venation characteristic of these plants, is sometimes seen in other plants, such as Kales, Parsley, a particular variety of Anemone japonica, and various water-plants where the venation is of a different character. These examples, however, says Mr. Druery, differ in character from cristate types, and are only akin to the plumose forms of Ferns, in which the extra foliose character is produced by an abnormal continuance of furcate venation carrying the tissues with it. In the Anemone especially the leaf seems incapable of forming a definite terminal growth, and continues developing at the edges until the growing season closes.—ED.]

*On examining a tassel to give the figures it baffled me, for after splitting up into about a score of strands, each of these had a bunch tassel, defying computation.

THE USE OF THE HOE.

It is against the interests of any grower of an outdoor crop to allow the ground he cultivates to remain untouched by the hoe for any length of time. The advice usually given in country districts to "hoe when there are no weeds, you are sure to do so when there are," is worth remembering, for whilst the secondary use of the hoe is to keep down weeds its primary value is to keep the surface of the ground moved. Frequent hoeings during dry weather are equal, if not superior, to a mulching, as the 2 inches deep of surface that is broken and powdered up by constant stirring acts as a mulch and serves to keep the ground cool and moist below. A piece of ground that is not frequently hoed during the summer soon becomes very dry and hard, and if there is a moderately long spell of drought the crop on it soon becomes yellow and starved-looking, due partly to the want of moisture, and in a greater degree to the lack of aeration in the soil. By keeping the surface stirred as deeply as possible with the hoe, the subsoil moisture is drawn upwards by capillary attraction for the benefit of the roots; heavy rains are more easily absorbed by the soil, and the ground becomes aerated and sweetened to the benefit of the crop.

The cost of regular hoeing is an important item, but this is paid for by the increased value of the crop. The cheapest way is to hoe by piece-work at so much per acre, the price varying according to the hardness of the ground and the amount of weeds on it. On light soils the highest price is about £1 per acre, the lowest about 8s.; but on heavy lands the prices may be about 25 per cent. higher. The average cost for a season in the former case works out at £3 to £3 10s. per acre, though the cost may be higher or lower according to the season. This may seem a big price to pay for keeping an acre of ground clean, but it must always be borne in mind that it is not only by the keeping down of weeds, but by increasing the value of the crops, that it more than compensates for the cost of cultivating of the ground.

The benefits of regular hoeing, however, depend to a great extent upon the person using the hoe, and also upon the nature of the ground. The latter has much to do with the manner in which hoeing can be done, heavy, clayey lands

being more difficult to deal with than light, sandy soil, though the benefits to be derived from frequent hoeings are the same in each case. On sandy or gravelly soils the hoe can be used at almost any time, even just after rain; but on close, stiff land, time must be allowed for the water to get away after heavy showers, or the ground will be puddled into a sticky mass unfit for anything. If, however, it is allowed to become too dry after rain before being hoed, it will get so hard that the hoe can make but little impression on it. If cut over with the hoe while it is damp, but not too wet, the ground can be hoed as deeply as possible, breaking all lumps to pieces at the same time, and so forming 2 or 3 inches of fine loose soil on the top, upon which the hoe can play at any time, whether it is dry or not.

Whatever the nature of the ground may be, the first hoeing of the season is an important one, for if this be properly done the ground will be loose and easy for any future working. This is where the personal element comes in, a deep and thorough hoeing being of the utmost importance, and though it may appear a simple thing, deep and regular hoeing is a task that can only be performed well after constant practice. This refers to the use of the draw-hoe, which is the only one that can be used to advantage on large stretches of land. The Dutch-hoe is useful for small gardens, but there is a danger that its constant use will form a hard crust just below the inch or two of surface soil, especially in heavy, or moderately heavy, ground. The draw-hoe, on the contrary, if properly used, breaks the ground differently each time it is used, to the benefit of the crop.

It follows, then, that if the hoe is our best cultivator, care should be taken that it is constantly used, especially during dry weather, always remembering that, as before-stated, the killing of weeds is the secondary consideration, the loosening and stirring of the surface soil being the first. *J. C.*

THE ALPINE GARDEN.

ASPERULA HIRTA.

THE charming little Asperula hirta is in bloom as this is written. It forms one of the most charming of Alpine flowers, and looks exceedingly pretty with its densely-tufted, deep green foliage spangled over with little heads of flowers of a rosy white. When grown in "hard" conditions it is exceedingly neat, and appears less liable to decay than under those frequently recommended for it. Here it is being cultivated on a high and fully-exposed part of my rock garden, sheltered from no wind, and fully exposed to the sun, as well as in a poor, hard and stony soil, such as one finds is appreciated by many Alpines in our moist climate. It is top-dressed, however, with well-decayed turf from the top-spit of very old pasture, and it seems to like this medium in which to form fresh roots. I have cultivated it under conditions which appeared to be more likely to suit, and gave it peat, loam and grit, with shelter from the north and east, and more frequent supplies of water than it has had this year; but it was never healthier or better flowered than it is at present. This little Woodruff is a native of the Pyrenees, and seems, in the drier parts of our islands, to require a moister position than in others. It was introduced in 1817. It is not widely grown, but should be sought after. I should prefer to plant it in July or August to any other time, giving it some shade when newly planted.

THREE NEW RAMONDIAS.

THREE new Ramondias deserve some notice, notwithstanding that they have not as yet attained sufficient size to show their true character, although all are in flower here at present. They are understood to come from an entirely different district from that in which the other Ramondias in cultivation have been found.

One of the best of the three has been named R. quercifolia, from the fancied resemblance of the leaves to those of one or other of the Oaks. It requires some effort of imagination to discover any near resemblance, save in the general outline; but they are, to some extent, lobed, and differ from those of the other Ramondias in form. The flowers are more like those of R. serbica Nathaliæ than would please those who wish a more distinct plant, and in this respect are not sufficiently different except to those particularly interested in the genus.

R. leucopetala is another of these forms, and its chief distinction lies in the colouring of the flowers, although these come near some seedling forms of R. pyrenaica alba. They are pale lilac, with what may be described as streakings or "shadings" of white or paler lilac. The foliage is smaller and less lobed than that of R. quercifolia.

In R. peregrina we have one whose name would lead one to infer that it has a somewhat running habit; but we are not yet in a position to judge as to this, and can only speak of the plant as it appears at present. Its leaves are the smallest of the three, and its flowers, which have been smaller than those of the two preceding, are the deepest in colour of the three, being probably best described by the term deep purple.

It must, of course, be kept in mind that these brief and general descriptions are from pot plants which have only been in my possession for a couple of months or so, and time may modify my impressions of their character. In foliage they come more nearly to R. pyrenaica than to R. serbica, and it is highly probable that they will be recognised by botanists as simply forms of that species. A few plants of R. quercifolia were included in the magnificent exhibit of Messrs. Cutbush at the Temple Show, but they were not shown conspicuously, and probably escaped the attention of many. *S. Arnott, Sunnymead, Dumfries, June 14.*

THE HARDY FLOWER GARDEN.

HYBRID BELL-FLOWERS.

IT would be valuable if Mr. E. Horton, who contributes the very interesting notes on hybrid Bell-flowers on p. 410, would give the authority for the parentage of some of the cross-bred plants which he names. C. × Hendersoni, for example, is, without qualification, stated to have resulted from the crossing of C. carpatica and C. alliariæfolia, but in the earlier editions of his *Dictionary of Gardening* Mr. Geo. Nicholson cites C. carpatica and C. pyramidalis as the parents. At a much later date the *Kew Hand List* gives the same data as Mr. Horton; hence there is reasonable room for doubt. My own knowledge of the plant compels me to adopt the parentage given by Mr. Nicholson, for in the leafage, the greater length of the petioles, and the disposition to form a more than usually woody rootstock, combined with the form of the flowers and the glistening character often seen thereon, are evidences, I think, of the influence of C. pyramidalis. The dwarf habit of the hybrid would suggest C. carpatica as the seed parent. If, however, C. alliariæfolia is one of its parents, such important features as the hoary tomentum, the type of inflorescence, the form of the flowers, and much of the form, as well as the leaf substance, have all been obliterated, which is unusual. For five years in succession I tried to raise a plant from C. carpatica turbinata × C. pyramidalis, and the plant I had hoped to obtain was a dwarfer one than C. × Fergusoni. Imagine my surprise when the only seedling I obtained worth saving was a plant so dissimilar from either parent that one might have imagined it to be a cross between C. pulla and C. rotundifolia. I named it C. × Profusion, in reference to its free-flowering character. In referring to C. × Balchiniana, your correspondent casts a doubt, as I think, wisely, upon the parentage given; and I have no hesitation in saying that I regard this as being no cross-bred plant at all, but simply a well-marked seedling variation. With considerable frequency this plant, or a portion thereof, loses all its variegated character, and assumes what is almost a replica of C. fragilis hirsuta, a variety known and grown thirty-five years ago. There was also a very hirsute form of C. Barrelieri, a plant of freer growth and with larger blossoms than those of C. fragilis. When C. × Mayi first appeared, the distinctly soft and woolly leaves caused much speculation as to their origin, for neither C. fragilis nor C. isophylla—the reputed parents—possessed such leaf characters. I made the following remark that: "If C. fragilis had aught to do with its origin, it was more likely to be through its variety hirsuta than the type." I can see no evidence in this remarkable plant of any influence of C. fragilis. The leaf formation, the petioles, the more abundant habit of growth, the size and form of the flowers, and even the whitish external colouration of the ovary—blush in C. fragilis—all these characters, together with a protuseness of flowering never seen in C. fragilis, point unmistakably to C. isophylla; moreover, there is nothing of the brittle character of C. fragilis in the handsome plant we know as C. × Mayi.

In Van Houtte's Bell-flower there is good external evidence of a plant of hybrid origin, and one has but to recall the stoloniferous shoots of the hybrid to connect it with such a plant as C. punctata, while the slender habit also suggests this species as a parent, although I more than suspect C. latifolia in some form or another of playing a small part in its origin.

In the genus Campanula a rare opportunity is afforded the enthusiastic hybridist, and the rock garden is as open as the herbaceous border to receive good additions of these plants. Readers not having prior experience should know that the anthers in the genus Campanula shed their pollen before the corolla opens. Hence the need for early emasculation and subsequent protection. *E. H. Jenkins, Hampton Hill.*

The Week's Work.

THE FLOWER GARDEN.

By HUGH A. PETTIGREW, Gardener to the Earl of PLYMOUTH, St. Fagan's Castle, Glamorganshire.

Care of hardy flowers.—Though some gardeners have the idea that after planting there is very little further to be done in connection with this class of plants, it is a mistaken one, for, unless the border is attended to both with care and regularity, no matter in what manner it has been arranged, it soon becomes disappointing. At the present moment there is much to be done on the borders, staking some of the taller-growing plants such as Hollyhocks, Phlox decussata, Gladiolus, Lavatera, etc., which should be done neatly and effectually, and in pegging down others, such as Phlox Drummondii, Verbenas, etc., thinning out the growths of strong growers, cutting off flowers that are over, and keeping the whole border free from weeds. Besides this, many plants require a little special treatment, according to the weather that is experienced. For instance, the Calochortus and Portulacca fare badly when the soil is soddened, and Eremurus blooms should all be guarded from the effects of the rain to keep them in perfection, while, on the contrary, if dry weather is long continued, watering must be resorted to if certain plants are to be sustained in good condition. Again, in addition to the above, arrangements should be always made for filling up gaps that may occur, either by planting out plants that are being reserved in pots, or resowing by some quick-growing annual, according to circumstances. The present and two following months are wonderfully rich in hardy flowers, and during this time the borders ought to be most interesting and attractive.

THE KITCHEN GARDEN.

By J. GIBSON, Gardener to His Grace the Duke of PORTLAND, Welbeck Abbey, Notts.

Peas.—The present season has been a good one for this crop generally, and late Peas promise to be remarkably good. The dry weather, however, if continued much longer, will give cause for anxiety. Plenty of water should be applied at the root and overhead as often as possible. Much more good is done by syringing than is apparent, and if this work is not done, the Pea moth will have every opportunity of puncturing the pods and depositing its eggs: but syringing would dislodge many moths, and so hinder them. The damage done by moths can easily be seen in the pale-green spots on the little pods, and they increase in size as the pods continue to grow. Peas from the latest sowings should be staked early, but at this

season of haymaking, etc., certain items of importance are apt to escape notice until it is too late to remedy the evil. Apply a mulch of long litter or lawn mowings between the lines at the same time.

Leeks.—Plant the main crop of Leeks as soon as the ground can be got into suitable condition. When lifting them for transplanting trim the roots and tops, and dibble them in deeply in lines drawn at one foot apart, allowing a space of six inches between the plants. Ground from which early crops of Potatos have been taken can be profitably used for Leeks. Those required for exhibition will need earthing up from time to time until the stem for about 15 inches is blanched. The earlier this can be done the better, as the more time will be allowed for the stems to thicken. Do not allow any soil to fall in between the leaves, as this cannot be readily got out, and is sure to show itself at a time when nothing of the kind should be apparent. Abundant overhead waterings are advantageous, therefore Leeks grow quickly in autumn when there are heavy dews in the morning.

Celeriac.—Encourage the plants to make good growth by applying a top-dressing, and occasional doses of liquid manure. In order to get fine roots, run the finger round the fleshy part so as to reduce the number of rootlets, when a better and more uniform head will be the result. This is best done when the heads begin to form and when quite young.

Late Savoys are generally of more value than the earlier crop, owing to the scarcity of other vegetables at the time. Make a separate plantation of these as soon as convenient, choosing a hardy, late variety.

Salading Onions.—Make a small sowing of these periodically, as they are very useful in salads. Any surplus seed may be used up in this way through the season.

Chicory.—Complete the thinning of this crop without delay if it has not been done already, as nothing is more injurious to vegetables of this class that depend on their summer development for their later success than the crowding of them together.

Weeds.—The dry weather has been suitable for the destruction of weeds, and it is necessary for all crops to be kept thoroughly clean and the soil well worked between the lines.

THE HARDY FRUIT GARDEN.

By W. A. COOK, Gardener to Sir EDMUND G. LODER, Bart., Leonardslee, Sussex.

Early Peach and Nectarine trees that are ripening crops should be given a good watering and some approved fertiliser should be employed. If the trees have been supplied with waterings from the farmyard tanks, they will be swelling their fruits rapidly. Do not syringe the foliage after the fruits commence to ripen. The first variety to ripen is generally Amsden June, closely followed by Waterloo. All early Peaches are unsatisfactory if not severely thinned, there being too much "stone" and too little flesh. Gathering needs to be done with exceeding care, taking them in the palm of the hand, or the fruits will be bruised. Place the fruits in a box or basket containing some fine wood-wool, which is the best material on which to convey them to the fruit room. The shelves in the fruit room should also be covered with a layer of this material. Nectarines do not ripen quite so early as Peaches—Earl Rivers and Cardinal are the earliest varieties, and these are followed closely by Lord Napier.

Strawberries.—Layer runners for subsequent planting out of door, and if sufficiently early they will bear excellent fruits next season; in these gardens we get the finest Strawberries from such plants.

Summer Pruning.—Persevere with the summer pruning of Apple and Pear trees, thinning out the fruits at the same time. The Apple crop being very heavy needs much thinning, or the fruits will be small in size and of bad shape. Large culinary varieties should only have the centre fruit left in each cluster. Blenheim Pippin should be well thinned, as should Cox's Orange, and Ribston Pippins, Peasgood's Nonsuch, Bismarck, Bramley's Seedling, Gascoyne's Scarlet Seedling, and others of the same type. The smaller varieties ought also to be thinned, if only to allow each fruit to become of a proper shape. In all cases where it is possible let trees bearing heavy crops be afforded manure water or a chemical manure.

Bush Fruit.—Gather all small fruits as Currants, Raspberries, etc., as they become fit for bottling or preserving purposes. The fruit should be in a dry condition at the time of gathering. On very light soils Gooseberries need frequent waterings, and occasionally with diluted farmyard manure water.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower to Sir TREVOR LAWRENCE, Bart., Burford, Surrey.

Odontoglossum citrosmum.—Now that the flowering season of this species is past, the plants may be repotted or top-dressed, as each may require. Shallow pans are suitable for them, and, being suspended, the flower spikes, which are pendulous, are seen to the best advantage. As a rule the growths produce but few roots, therefore the pans should be small in proportion to the size of the plants, ample drainage should be afforded, and the rooting medium may consist of peat and sphagnum-moss, with a handful of small crocks mixed in to keep it porous. It is advisable to pot rather firmly, as by so doing the pseudo bulbs retain their plumpness better during the season of rest than if the materials are loose. Suspend the plants to the roof of the Cattleya or Mexican house in a light, well-ventilated position. Afford water carefully till the new growths and roots are fully active, but afterwards let abundance of water be given until growth is fully made up.

Cattleyas.—C. Dowiana, C. D. aurea, C. Gaskelliana, C. labiata and C. guttata Leopoldi have made considerable progress with their new growths, and many flower sheaths are noticeable. While in this stage care should be taken that water is not allowed to remain in the growths. The plants will require considerable water at the root until the flowers are open when less will suffice. Such Cattleyas as C. Mendeli, C. Mossiæ, C. Skinneri, C. intermedia, C. Lawrenceana, C. Schroderæ and C. Warneri, also many hybrid Cattleyas, Lælias, Lælio-Cattleyas, &c., will require attention as regards repotting, &c., full instructions for which were fully given in my *Calendar* for May 5, p. 278. Plants of Cattleya gigas may also be repotted when they have passed out of bloom, as very soon after this the current season's growth will send out from their base a large number of roots that will at once enter the new potting compost, and thereby become quickly re-established. This work should not be delayed, as after the roots start, any disturbance of the compost is attended with danger.

Lælia purpurata and L. tenebrosa should be placed in a cool, well ventilated part of the house, affording just sufficient water at the roots to keep the pseudo-bulbs plump, but nothing should be done that will induce the growths to start, as the earlier growths are seldom satisfactory, whereas the late summer and autumn growths are stronger, and invariably produce flower sheaths at the proper season. Lælia Dormaniana, L. Perrini, L. elegans and Lælio-Cattleya Schilleriana may be repotted if necessary, afterwards affording them generous treatment. Cattleya Bowringiana has begun to make new growths and should be elevated well up to the light, and where there is a good circulation of air. The plant should not be disturbed now, the proper time for repotting being soon after the flowering stage, as it is then that the new pseudo-bulbs produce most roots.

PLANTS UNDER GLASS.

By B. CROMWELL, Gardener to T. SUTTON TIMMIS, Esq., Cleveley, Allerton, Liverpool.

Need for top dressings.—Any specimen plants which have not been repotted for a season, whose roots are in a healthy and active condition, would (in most cases) derive much benefit from a top dressing with decayed cow manure and the siftings of charcoal and sand. The young roots would soon push into this material, and plants advancing in the flowering stages would show a marked improvement from this increase of root action.

Hard wooded plants out of doors.—Although a sheltered position has been chosen, a little extra care will be necessary in securing such plants as Azaleas, Heaths, Camellias, and greenhouse Rhododendrons from the effects of strong winds. If stood on a bed of coal ashes and made perfectly level, they may be safely ensured by driving down three strong stakes sufficiently deep in the ground and close to the rim of the pot; this should be done as each plant is placed in position, and there will then be no further need for anxiety. Syringing with water overhead each day will keep the surroundings cool during hot, dry weather. The plants generally will then be improved by the outdoor treatment. Spray the plants occasionally with XL-All insecticide, as thrips are usually troublesome on plants placed outside. Considerable care is needed to prevent greenhouse Rhododendrons that have completed their growth from starting again; they are much more liable to do this than either Azaleas or Camellias, and although they enjoy a liberal quantity of water at their roots, they should not be allowed to become saturated either from the water pot or heavy rains. Lapagerias may also be placed out of doors in a shady position, and as they are now approaching their flowering stage, the substance and colour of the flowers will be improved; afford water freely to the roots, and a weak stimulant may be applied at every alternate watering.

General remarks.—Now that most of the plants have been repotted, the work in the houses will consist of the tying and staking of plants, and in keeping everything in a state of perfect cleanliness. In the staking of plants use stakes which have been previously painted, and as few of these as possible, so that the plants may have a natural appearance of growth. Bamb o canes can be had in various sizes, and are the most economical to use, hence there is no excuse for having plants roughly staked. Propagate the young growths of choice varieties of Pelargoniums by placing them singly in small pots, and putting them in a frame in which the atmospheric temperature is 55° to 60° during the day; afford a little ventilation at night, and see that the cuttings are kept free from aphis.

FRUITS UNDER GLASS.

By T. W. BIRKINSHAW, Gardener to Lt.-Col. Sir CHAS. HAMILTON, Bart., Hatley Park, Bedfordshire.

Tomatos.—The first batch that was planted in the final pots in the early part of February and have since grown in a warm house will now have finished fruiting. If plants are infested with the white fly, they should be carefully cut out and taken to the fire heap. Any fruits that are still green may be cut and placed on shelves in a warm house to ripen; they will be very useful for the making of soups, &c. Successional plants succeed much better when planted out in narrow borders, or even in wooden boxes made about 8 inches deep, a foot wide, and 3 or 4 feet long, according to the amount of space at disposal. Plants that have set their fruits should now be given a top dressing of loam, with a little bone meal mixed with it. Tomatos are very fond of bone meal, also diluted liquid manure, and soot water occasionally. Continue to keep all side growths pinched out, and when the fruits are ripening, some of the foliage should be cut away, in order that air may the better circulate about the plants. Those plants at present in flower may be given a gentle tapping each day, to assist the distribution of the pollen, and therefore the pollination of the flowers. Some varieties set their fruit much more freely than others; such, for instance, as Duke of York, Vick's Criterion, Northern Beauty, and The Peach. "The Peach" is delicious for dessert, but is only small in size. If good-sized Tomatos are required for exhibition purposes, the bunches should be thinned out freely while in their early stages of growth.

Strawberries.—Young plants that were layered into 3-inch pots early last month should now be in such a condition that they may be severed from the mother plants without suffering injury. They should be brought from the beds and be placed on the sides of the garden paths, or, if it is very hot, plunged in fine ashes. In this position they will succeed very well until they are ready for putting into the pots in which they will fruit.

Cape Gooseberries.—If ample accommodation exists in the fruit houses, these should be planted out at once. But where room is limited a few can be grown in 9- or 10-inch pots, using rather poor soil, or the plants might make too much growth, but set very few fruits. The fruits are very pretty when ripe, and the flavour is somewhat peculiar. The plants require plenty of sun, light, air, and water.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, *as well as specimens and plants for naming, should be addressed to the* **EDITOR, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Special Notice to Correspondents.—*The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.*

Illustrations.—*The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c., but he cannot be responsible for loss or injury.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.*

Local News.—*Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists*

APPOINTMENTS FOR THE ENSUING WEEK.

SATURDAY,	July 14	Glasgow Fair. Dutch Gardeners' Soc. meet.
TUESDAY,	July 17	Roy. Hort. Soc. Coms. meet. Roy. Scottish Arboricultural Soc. Exh. at Peebles (4 days).
WEDNESDAY,	July 18	Nat. Rose Soc. & Roy. Caledonian Hort. Soc. combined Exh. at Edinburgh. Glasgow Fancy Sh.
THURSDAY,	July 19	Newport Fl. Sh. Rochampton Cottage Fl. Sh. at Dover House. Dunfermline (Carnegie Trust) Fl. Sh. (2 days). Great Yarmouth Fl. Sh.
FRIDAY,	July 20	North Lonsdale (Ulverston) Rose and Sweet Pea Exh.
SATURDAY,	July 21	German Gard. Soc. meet.

AVERAGE TEMPERATURE for the ensuing week, deduced from observations of Forty-three Years at Chiswick: 63.4

ACTUAL TEMPERATURES:—

LONDON.—*Wednesday, July* 11 (6 P.M.): Max. 68°, Min. 53°

Gardeners' Chronicle Office, 11, Wellington Street, Covent Garden, London. *Thursday, July* 12 (10 A.M.): Bar., 30·1; Temp., 65°; Weather—Fine.

PROVINCES.—*Wednesday, July* 11 (6 P.M.): Max. 61°, England, South-east; Min. 54° Ireland, North-east.

SALES.

FRIDAY—

Importations of Orchids, Established Orchids, Cycas revoluta, also retarded bulbs and roots, at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 12.45.

The Summer Show of the Royal Horticultural Society.

Holland Park has one great advantage over the Temple in the greater space available, and, consequently, in the enhanced comfort of exhibitors, exhibits, and visitors. The R.H.S. is thus under a great obligation to Mary Countess of Ilchester for the privilege of holding its show in the paddock fronting the picturesque and historic mansion known as Holland House. The Temple is rich in historic associations, but it may be doubted whether the average flower-show visitor pays much heed to far-off abstractions of that kind. At Holland Park the open space and the delightfully picturesque mansion compel attention, even from the most thoughtless. Entering direct from the busy thoroughfare of the Kensington Road to the avenue of Elms with an undergrowth of Foxgloves, Campion and the ripening capsules of the Wood Hyacinth, it is impossible for the moment for the visitor to realise that he is still in the midst of London. At this season the foliage is attractive, but a second glance shows only too plainly that the trees have passed their best and that the Elms are experiencing the effect of London atmosphere and excessive drainage, whilst the once noble Cedars are spectral monuments of bygone stateliness. But on a fine July day and on such an occasion there is no need to dwell upon anything but the excellence of the show and the beauty and interest of its surroundings. From the full report given on another page it will be seen that the great summer show of the R.H.S. was as attractive as any of its predecessors, although we cannot indicate any particular exhibit as standing out prominently by reason of its novelty or interest. The ordinary flower-show visitor, however, would not have noticed the deficiency, so entrancing was the feast of beauty laid out for his delectation.

The luncheon given by the council to the members of the several committees and the judges was a pleasant function. The friendly gathering and the recognition thus afforded by the governing body of the disinterested labours of the committees all through the year do much to promote mutual understanding and goodwill, and if congratulations were freely exchanged between the President, as the mouthpiece of the Council, and the representatives of the committees and judges, as voiced by Sir Michael Foster, Sir John Llewelyn, and Mr. Challis, those congratulations were amply justified.

The Meteorological Society had an interesting exhibition hard by, but we venture to think that anyone conversant with the affairs of the R.H.S. would hardly need to inspect the instruments to realise that for the present the indications are "set fair."

But the Meteorological Society's display did not constitute the only collateral subject of interest. By the thoughtful kindness of Mary Countess of Ilchester the private gardens of Holland House were thrown open for the inspection of visitors on payment of a small fee, the proceeds of which are to be devoted to the gardening charities. Judging from the numbers of persons we saw availing themselves of this privilege, the charities should benefit substantially, and, as to the visitors, they must have been obtuse indeed if they were not charmed with the delicious old-world garden, and the varied outlines of the grey mansion, with its gables and turrets, its projecting bays and deep recesses. How often have we heard the lament that it is impossible to grow Roses in London? Those who saw the long double border of Caroline Testout Rose in full beauty in the garden at Holland House were literally amazed, and the wonder was not confined to the casual visitor, but found expression even from expert cultivators, whose experience is gained in country parks and gardens far removed from the untoward climatal surroundings entailed by a London atmosphere. Holland House gardens, too, furnish an object-lesson to controversialists prone to wrangle over the comparative merits of the formal and the natural style of gardening. We do not think the most rabid opponent of the formal style could object to the quaint Elizabethan flowerbeds so thoroughly in keeping with the architectural features around them, nor can we conceive the most ardent devotee of formalism finding ought to object to in the shrubbery walks, the dells, and other features of this delightful garden lying between the vast highways of the Hammersmith Road on the one side and the Bayswater Road on the other. Flower shows come and go and repeat themselves, but the charm of a house and garden like Holland House is perennial and persistent.

OUR SUPPLEMENTARY ILLUSTRATION this week shows how a flat, monotonous surface may be broken up and converted into a rocky, fern-lined dell through which a cascade comes tumbling over the rocks as if to the manner born. The "formal" gardener may scoff at the artificial dell and the sham rocks. Let him indulge his artistic taste if he will, but let him not attempt to deprive others of efforts which are in every way as charming as those of the best designed terrace garden. We do not know what were the conditions in the Torquay garden, shown in our illustration, before Messrs. PULHAM took it in hand, but our readers can see for themselves what a beauty spot they have created, and the gardener and the botanist can readily appreciate the opportunity offered for the protection and culture of their favourite plants.

THE BOTANICAL MAGAZINE.—The July number contains coloured illustrations of the following plants:—

EUPHORBIA PROCUMBENS (*Miller*), tab. 8,082.—A very curious dwarf Spurge with short, thick, succulent, spineless stem and numerous spreading branches, short, curved, subulate leaves, and heads of yellow flowers, provided with thick scarlet, kidney-shaped glands. The figure is taken from a plant in the collection of Mr. JUSTUS CORDEROY, here described by Mr. N. E. BROWN.

DEUTZIA WILSONI (*Duthie*), tab. 8,083.—A handsome species collected for Messrs. VEITCH in Western China by Mr. WILSON. The leaves are broadly lanceolate, sharply toothed; the numerous white flowers are terminal, much branched panicles.

PAPHIOPEDILUM GLAUCOPHYLLUM (*J. J. Smith*), tab. 8,084.—A species allied to P. (Cypripedium) Chamberlainianum, but differing in its broader, self-coloured, glaucescent leaves and pubescent petals. It is a native of Java. The plant figured flowered at Kew, and is described by Mr. ROLFE.

GURANIA MALACOPHYLLA (*Barbosa Rodrigues*), tab. 8,085.—A climbing, tendril-bearing Cucurbit, with soft, cordate, ovate leaves, and heads of scarlet flowers on long axillary stalks. The specimen was sent to Kew by Mr. ED. ANDRÉ, who originally described the plant in the *Revue Horticole* 1904, p. 388, as G. eriantha, but G. eriantha, as pointed out by Mr. SPRAGUE, has spicate, not globose inflorescence.

GENISTA CINEREA (*De Candolle*). tab. 8086.—A shrub, native of the West Mediterranean region, with ascending, slender, silky branches, and linear leaves. The papilionaceous flowers are yellow and disposed along the ends of the branches; Kew. The plant is described by Dr. STAPF.

THE TEMPLE SHOW.—The average Briton is aware of his lack of taste in decoration, and of his inability to compete with Frenchmen and Belgians in this particular. The *Revue de l'Horticulture Belge* takes exception to the arrangement of the exhibits of the Temple Show, where, although space is so precious, far more variety might be introduced in the staging and grouping. "The exhibition of this year," says the writer, "differed but little from its predecessors. The tents in their old places, the same arrangements of the exhibits, all show no desire to produce a good general effect. In this respect the shows of the Société Nationale d'Horticulture de France and the Ghent Quinquennials are far in advance." The English are men of business essentially and expose their exhibits to attract clients. If their plants were arranged more tastefully and artistically and temptingly it would be a gain to trade exhibitors. What is especially required is a larger and more suitable exhibition ground, as the number of entries increases yearly." We must all acknowledge the justice of these criticisms, the more so, as we know, more fully than our Belgian contemporaries can do, the reasons for the deficiencies he points out.

HORTICULTURAL CLUB.—The annual excursion will take place on July 26, when the members will leave the Great Central Railway Station (Marylebone) by the 10.5 train, arriving at Wendover at 11.12, where brakes will be in readiness to convey the party to Halton, the beautiful country seat of ALFRED DE ROTHSHILD, Esq., who most kindly provides luncheon. In the afternoon the party will drive to Tring Park (three miles), where, on the kind invitation of Lord ROTHSCHILD, tea will be provided, after which the gardens will be visited, and also the museum of the Hon. WALTER ROTHSCHILD. The return train leaves Wendover at 7.45 for, Marylebone. The inclusive cost of each ticket will be 11s. 6d. Those wishing to be present will kindly send their names, on or before July 16, to Mr. HARRY J. VEITCH, East Burnham Park, Slough, who is undertaking the necessary arrangements.

NATIONAL ROSE SOCIETY'S NORTHERN SHOW, EDINBURGH.—We are asked to state in connection with this show, which will be held on July 18, that the Great Northern Railway will issue special cheap tickets at the reduced fare of £2 0s. 10d. third class, and £3 11s. first class return from King's Cross, available for three days, with sleeping accommodation to be attached to the 8.45 p.m. train on July 17. Early application to Mr. C. C. DANIELS, Chief Passenger Agents' office, King's Cross, is particularly requested. Anyone forming a party of five can join this train at any stopping place, but to obtain the reduction tickets must be applied for beforehand as above. Any further information can be obtained of H. E. MOLYNEUX, hon. treasurer, National Rose Society, 80, Cannon Street, E.C.

SIR DANIEL MORRIS.—What may be done by energy, ability, and perseverance is well illustrated by two votes of thanks which we find recorded in the *Agricultural News*. When fungoid disease destroyed the crop of Sugar Canes in Barbados, it was suggested that an alternative industry should be started. Every one agreed that it was desirable, but few thought it was practicable.—"But through the energy and tact displayed by Sir DANIEL MORRIS and his staff, we have" (says a speaker at the conference of cotton growers) "an alternative and a paying industry." A vote of thanks was passed unanimously. In the same periodical, a few pages further on, we find that the clergy of the Church of England in the island of Antigua assembled at a clerical meeting resolved formally: "That the work in connection with the agricultural education in secondary and elementary schools which has been developed and fostered by the Imperial Department of Agriculture in the island of Antigua, has been of great benefit to the schools and education generally: That the work now being done is likely to lead to good results in the future: That their grateful thanks are hereby tendered to the Imperial Department of Agriculture for their valuable help in the past, and it is hoped that every effort may be made to continue the work on the present lines." Sir DANIEL'S advice would be valuable in securing the passage of the Education Bill in such a shape as to be satisfactory to all parties!

"REWARD" STRAWBERRY.—Messrs. LAXTON BROTHERS have sent us samples of their new Strawberry bearing the above name. The "fruits" are of variable size, the largest measuring $1\frac{3}{4}$ inches in the longest diameter. In form they are variable, some being conic, others flattened and spade-shaped. The colour is crimson and the carpels (so-called seeds) are slightly embedded, and distributed over the whole surface of the "fruit." The flesh is firm, solid, deeply coloured, rich and slightly acidulous in flavour. We know nothing of its cropping qualities, but judging from the samples sent, it travels well and amply deserves the Award of Merit it received from the Royal Horticultural Society.

PARIS MUSEUM OF NATURAL HISTORY.—M. P. H. LECOMTE has been appointed Professor of Systematic Botany in place of M. BUREAU resigned.

POSTAL CHANGES.—The following reductions of postal charges are now officially announced:—Money orders payable abroad.—The poundage charged on money orders issued in the United Kingdom for payment abroad for sums not exceeding £1 is now reduced from 4d. to 3d. Postal orders.—The poundage chargeable on certain values of postal orders is reduced from the present time, as follows: On orders for 2s. and 2s. 6d. the charge is ½d. instead of 1d.; on orders for 11s., 11s. 6d., 12s., 12s. 6d., 13s., 13s. 6d., 14s., 14s. 6d., and 15s. the charge will be 1d. instead of 1½d. Parcel post.—The rates of postage for inland parcels exceeding 4 lb. in weight is reduced: Not exceeding 1 lb., 3d.; exceeding 1 lb. and not exceeding 2 lb., 4d.; exceeding 2 lb. and not exceeding 3 lb., 5d; exceeding 3 lb. and not exceeding 5 lb., 6d.; exceeding 5 lb. and not exceeding 7 lb. 7d; exceeding 7 lb. and not exceeding 8 lb., 8d., exceeding 8 lb. and not exceeding 9 lb., 9d.; exceeding 9 lb. and not exceeding 10 lb., 10d.; exceeding 10 lb. and not exceeding 11 lb., 11d.

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

EXHIBITING VEGETABLES.—In reply to Mr. J. A. Simpson (p. 8), if I were called upon to judge the varieties mentioned, each would receive credit, but if the schedule read—six distinct kinds of vegetables, with no other remarks, and Parsley in a pot was included, I should at once disqualify the exhibit as I do not consider Parsley a vegetable, and it should only be included in collections of herbs or in separate classes set apart for it. Much as I have admired the pots of beautiful Parsley exhibited in Scotland in the separate classes, I think the schedule should stipulate for one plant only and not for one pot, which is very misleading, as it may contain two or more plants. I also consider the varieties or kinds as mentioned by Mr. Simpson a very weak set; and, further, would any judge, providing Parsley were allowed by the wording of the schedule, give it the preference to a good dish of Carrots or Celery? *W. J. Pritchard, Elstree.*

GARDENERS' ROYAL BENEVOLENT INSTITUTION AND ROYAL GARDENERS' ORPHAN FUND.—I beg to call your attention to a special effort that is being made locally in Derbyshire to aid the funds of these two societies. It is proposed to hold an exhibition and sale by auction at the Auction Mart, Derby, on Wednesday, August 1 next, for which gifts are solicited of plants, flowers, fruit, vegetables, or any other articles. At this season when there is such a profusion of garden products, I trust this appeal will meet with a generous response, feeling certain that all who are interested in gardening will readily give of their abundance to assist those whose past efforts have yielded so much to their pleasure. To enable the matter to be properly advertised, I would ask intending contributors to forward particulars of their gifts without delay, so that proper arrangements can be made. All plants, &c., should be delivered here on the day prior to, or not later than 9 a.m. on the morning of, the exhibition. The perishable nature of these articles renders an earlier sending unadvisable. The use of three spacious sale rooms has been given free of cost by Messrs. Galbraith, Bethune & Co., Ltd., who have also offered to conduct the auction sale and give their fees to the funds. A great expense has thus been saved, and the only costs to be defrayed are those of advertising, &c. The entire proceeds will be equally divided between the two societies. The exhibition will be opened at 10.30 a.m. on Wednesday, August 1. The sale by auction commences promptly at 2 p.m. Admission tickets (6d. each) can be obtained on application. Programmes giving the names of donors and particulars of their gifts will be printed in due course, price 3d. each. A limited number of advertisements can be inserted. Notice of contributions will be gratefully received and acknowledged by the local honorary secretary, Mr. W. H. Cooke (gardener to the Rt. Hon. Lord Belper), Kingston Hall Gardens, Derby; or by Messrs. Galbraith, Bethune & Co., Ltd., Auctioneers, Surveyors and Land Agents, Market Place and Derwent Street, Derby, from either of whom tickets and all further information can be obtained. *R. T. Bethune.*

CARTER'S MONARCH STOCK.—A new and very fine strain of Ten-week Stock is Carter's Monarch. Our trial proves that it comes into bloom particularly early, and the great length of spike favours a continuance of blossom for a long period. Its fragrance, which at any season is most refreshing and agreeable, fills the air during the early morning and evening. The immense size of individual pips, together with the unusual length of spike, makes a bed of these plants very effective, and certainly for the flower basket they possess considerable value in early summer. The seeds were sown in March, and seedlings planted out early in May provided a good display in June. Many visitors who have inspected them agree that the strain is an excellent one, the bold spikes, vigorous constitution of the plant, and purity of its colour making an impression that will probably remain for some length of time. As with all other Stocks there is a proportion of single flowers, but the percentage is below the average. It would seem that the new Monarch is a glorified form of the now well-known and popular Princess Alice—a favourite Stock with everyone. *W. Stugnell.*

THE WEATHER IN THE NORTH.—After some very fine dry weather, lasting from June 6 till June 27, the weather in the north-eastern counties underwent a remarkable change, with disastrous results to many tender plants in fields and gardens. Slight frosts were experienced from June 28 to July 2, that of the morning of July 1 being the most severe, 1° being registered in a Stevenson's lowered screen, which means at least 3° of ground frost at this season of the year. A cold northerly wind helped to accentuate the evil wrought amongst tender plants. Potatos were badly blackened in places. Kidney Beans suffered very much, also Begonias, Ageratums, Dahlias, and other bedding plants. I very much fear that Strawberries in full flower, and also Raspberries in the same condition, have been badly injured. These two crops looked remarkably well previously and were quite a contrast to several other fruit crops this season, such as Plums and Cherries, which are absolute failures. Gooseberry crops are under the average, while Currants are full crops. The Apple crop will, I fear, be a very light one. This may be the effects of the cold wet autumn of 1905, followed by similar conditions in spring, which culminated in a rainfall during May of 5·78 inches, with an extremely low temperature. The month of June was very dry. Vegetable crops, though late, are looking well. As a result of the recent frosts, the common bracken (Pteris aquilina) has also been blackened, showing in a marked degree the unusual nature of the recent meteorological conditions in Ross-shire. *W. Laing Mutty, Ardross, Alness, N.B.*

SOCIETIES.

ROYAL HORTICULTURAL.

SUMMER SHOW AT HOLLAND HOUSE.

JULY 10, 11.—After an interval of one season, when the Royal Horticultural Society held its summer show in the grounds attached to the Royal Hospital at Chelsea, the Society was again privileged to visit Holland Park, Kensington, on the above dates. On former occasions it has been obvious to everyone attending these shows that no situation in London could possibly be more suitable for the holding of a horticultural exhibition than the grounds attached to this fine old residence at Kensington, and on the present occasion the scene appeared brighter and more glorious than ever. The weather was fair, if not fine, and the number of visitors appeared to be much larger than at previous exhibitions, whilst the exhibition itself was quite as attractive as previous ones have been.

Orchids, though less numerous than at the Temple Show, made a good display, and the ORCHID COMMITTEE recommended four First-Class Certificates, one Botanical Certificate, and six Awards of Merit.

The FLORAL COMMITTEE had a large number of novelties to inspect, and amongst the awards

were one First-Class Certificate and ten Awards of Merit.

The FRUIT AND VEGETABLE COMMITTEE did not make any award to a novelty.

There was a large attendance at the luncheon, at midday, when SIR TREVOR LAWRENCE presided, and was supported by Sir J. T. D. Llewelyn, Sir Michael Foster, Sir Daniel Morris, Captain Holford, and most of the members of the Society's committees.

The arrangements for the show, which certainly involve considerable extra work on the part of the secretaries and upon Mr. S. T. Wright, Mr. Frank Reader, &c., were satisfactory.

Owing to the kindness of Mary Countess of Ilchester, the private gardens were opened to the public for the benefit of the two gardening charities. The charge made for admission was one shilling, and we believe that a sum of £156 12s. was thus realised.

Floral Committee.

Present: W. Marshall, Esq. (Chairman), and Messrs. J. F. McLeod, Amos Perry, C. T. Druery, T. W. Turner, W. P. Thomson, W. Bain, C. R. Fielder, W. Howe, R. Wilson Ker, C. E. Shea, Geo. Nicholson, Jno. Jennings, G. Reuthe, R. C. Notcutt, R. W. Wallace, A. R. Goodwin, M. J. James, Ed. Mawley, W. G. Baker, Jno. Green, Chas. Dixon, F. Page-Roberts (Rev.), Geo. Paul, H. J. Cuthbush, C. J. Salter, H. J. Jones, Chas. Jeffries, H. B. May, Jas. Walker, W. Barr, J. W. Barr, and R. Hooper Pearson.

ROSES.

Messrs. BEN R. CANT & SONS, The Old Rose Gardens, Colchester, staged a beautiful lot of garden Roses, and boxes of specimen blooms, principally H. T. and T. varieties. Countess of Derby is a new H. T. The flower is of good shape, the colour being cream, tinted with faint rose. The new seedling, Mrs. O. G. Orpen, was prominent in several vases. Lucy Carnegie, although small, is a charming flower, the sulphur-coloured centre being set off with outer rosy petals. Well-known varieties occupied the exhibition boxes.

The KING'S ACRE NURSERY CO., Hereford, showed a charming exhibit of Roses. They had bunches in vases at the back, and boxes containing larger blooms in the front. Such beautiful varieties as Bessie Brown, Ulrich Brunner, Killarney, Mildred Grant, and Mrs. R. G. Sharman Crawford were shown in exhibition style, while at the background were Rambler and Polyantha varieties arranged in pyramidal shape.

Messrs. WM. PAUL & SON, Waltham Cross Nurseries, Herts, made a beautiful display of Roses in a corner of one of the tents. The great poles, covered with such fine Roses as Waltham Rambler, Crimson Rambler, Sweetheart (Wichuraiana), and other varieties, were extremely effective, and cut flowers of Hybrid Tea and other exhibition Roses were shown in baskets and other receptacles, in which they were massed in bunches.

One of the most delightful ground exhibits in the large Orchid tent was one from Messrs. R. & G. CUTHBERT, Southgate Nurseries, Middlesex. It was composed of Rambling Roses, including Lady Gay, Hiawatha, and most of the novelties we have seen in this section of Roses. The plants were arranged thinly, and between them was a miscellaneous collection of plants in flower, including hybrid Verbenas in the newest varieties, Lilium longiflorum, L. auratum, L. speciosum, L. giganteum, Hydrangea Hortensia, Ivy-leaved and zonal Pelargoniums, Lilies of the Valley, and other species. The effect was brilliant and varied.

Messrs. HOBBIES, LTD., Dereham, Norfolk, had an exhibit of Roses which was remarkable for the pretty standards of Wichuraiana and Polyantha varieties which it contained. These standards had an effect similar to that of a bouquet. In other forms were Hiawatha, Lady Gay, Dorothy Perkins, &c., and very fine blooms of the varieties Frau Karl Druschki and Mildred Grant.

Messrs. PAUL & SON, The Old Nurseries, Cheshunt, also had a corner exhibit in the large tent, and arranged their display of Roses much in the same manner as the firm is in the habit of doing at the Temple Show. Both the plants and the cut flowers were excellent in quality, and they had a pretty effect. Many of the cut flowers were arranged in small, green bucket-like receptacles, and appeared at first sight to be well-flowered dwarf plants of the varieties represented.

Messrs. ALEX. DICKSON & SONS, Newtownards, co. Down, showed vases of Roses, some of which were new varieties, that named Mrs. Jardine receiving an Award of Merit. The "single" Irish Elegance was much admired.

Messrs. FRANK CANT, LTD., Braiswick Rose Gardens, Colchester, showed Roses that were of superb quality. Among the more notable blooms were Liberty, Prince de Bulgarie, Mdme. Moreau (gold and rose), Irish Engineer, and Irish Beauty (carmine and white respectively), Killarney, and Florence Pemberton.

Messrs. GEO. JACKMAN & SON, Woking Nursery, Surrey, occupied much of the central tabling in one of the large tents with an array of hardy flowers and Roses. The border flowers were a representative lot, and embraced many new and choice varieties. Among the Roses was a magnificent box of Mildred Grant. An epergne of the white Maman Cochet was also very fine.

Messrs. GEO. COOLING & SONS, Bath, exhibited a nice collection of Roses. Sprays of Rambler varieties hung over from the back, the small white Rover's Musk formed a plume of Roses, with vases and boxes of larger-flowering kinds, such as Hugh Dickson, Mrs. W. J. Grant, Capt. Hayward, Killarney, Comtesse de Nadaillac, and Souvenir de Catherine Guillot, all in capital form.

A small group of Roses came from Mr. ERNEST E. GRIMSON, York House, Sutton.

BEGONIAS.

Messrs. BLACKMORE & LANGDON, Tiverton Hill Nursery, Bath, staged a beautiful exhibit of tuberous-rooting Begonias. The flowers were very large, of first-class form, and they showed exquisite colourings. Many new varieties were shown, Purity being one of the best (fig. 18), Mrs. G. Fry has large petals of a clear salmon shade; Beatrice has wavy petals, which are pale yellow at their base, passing to a pale-salmon tint. Miss Dorothy Hardwick, Percy Foster (scarlet), Mrs. W. L. Amslie (yellow), and Mad. A. Patti (of the Picotee type) were all notable varieties in this exhibit.

Mr. A. LL. GWILLIM, Cambria Nursery, New Eltham, Kent, exhibited a beautiful batch of tuberous-rooting Begonias, single and double varieties being about equally represented. Among the double forms notable varieties seen were Mary Pope (white), Margaret Gwillim (yellow), Morning Star (a new white variety), and Pride of Eltham (rich primrose).

Messrs. JOHN LAING & SONS, Forest Hill, London, showed many single and double-flowered varieties. Yellow, pink, salmon, white, scarlet, and other shades were seen, the flowers being very showy. Lady Sefton (rosy pink), Lord Craven (a deep scarlet, almost crimson, shade),

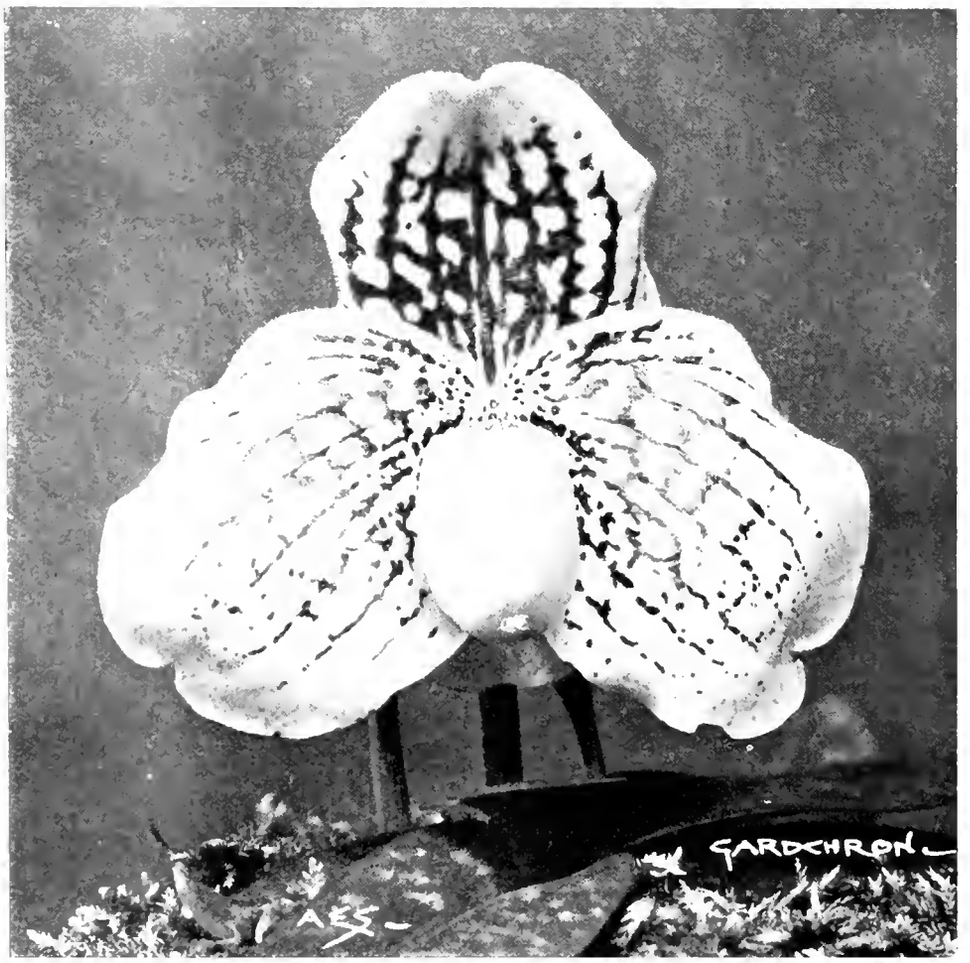

FIG. 16. CYPRIPEDIUM GODEFROYI VAR. HODGKINSONI.
(See Report of the Holland House Show, p. 36.)

and Mrs. Arthur Hall (soft salmon) may be mentioned as varieties of merit.

Messrs. THOS. S. WARE, LTD., Ware's Nursery, Feltham, showed tuberous-rooting varieties of much merit. The flowers were very large and the plants well grown. The beautiful shades of colours common in this plant were well represented—soft shades of salmon, seen in John Peed, Duchess of Connaught, Mrs. W. H. Edwards (with white edging), scarlet, as in William Marshall, King Edward VII. (new), and George Pike, white and blush, well shown in Mrs. W. H. Edwards, Mary Pope, Countess of Ilchester, &c.

SWEET PEAS.

Messrs. G. STARK & SON, Great Ryburgh, showed about 40 varieties of Sweet Peas, and variegated Nasturtiums, labelled Stark's Hybrids. A new carmine-coloured Sweet Pea was shown under the name of George Stark.

E. MOCATTA, Esq., Woburn Place, Addlestone (gr. Mr. Thos. Stevenson), showed a nice assortment of Sweet Peas in about 40 varieties.

Sweet Peas in variety were also shown by Mr. Ernest Poupart, Twickenham.

Mr. Henry Eckford, Wem, Shropshire, showed flowers arranged in vases. He staged the new variety Horace Wright, also Henry Eckford, whose shade of colouring is unique; Miss Willmott, Queen of Spain (new, the shade is flesh colour), Maud Guest (new), &c.

Messrs. John King & Sons, Coggeshall, displayed a large number of Sweet Peas in most of the newer and better varieties.

Mr. C. W. Breadmore, Winchester, showed vases of Sweet Peas. They had the new varieties Miss Audrey Crier, Elsie Herbert, Etta Dyke, and Dora Cowper, all of which are described on p. 38. Helen Lewis, the medal flower of last year, Mrs. W. Wright, Henry Eckford, Miss Willmott, &c.

Messrs. Carters, High Holborn, London, displayed vases and epergnes of Sweet Peas in great variety.

Hardy Flowers.

Messrs. Gunn & Sons, Olton, Birmingham, displayed about 30 varieties of Phlox decussata. The spikes were cut with long growths that enabled them to be arranged to great advantage. Josephine Gerbaud, Eugene Iris, Coquelicot, Espérance, and [illegible] are the more notable varieties.

Mr. Amos Perry, Winchmore Hill, London, N., made a fine display with water-loving and bog plants, and in which the endless variety of tints seen in Grasses, Bamboos, Typhas, Rushes, Eulalias and other tall foliage plants were shown to advantage. Gunneras, Ferns, Spiraeas, Iris Kaempferi, a notable feature, Water Lilies, which were resplendent with beauty, and a representative collection, all contributed to a charming display, suggestive of much that could be done in the garden on similar lines.

In the open Mr. Perry arranged a very fine group of herbaceous plants.

Mr. G. Reuthe, Keston, Kent, staged an interesting lot of plants—hardy Heaths, [illegible] choice flowering shrubs, Eremuri, Rhododendrons, Ixias, and many others. The [illegible] Campanula Moerheimi was especially good.

Gaillardias and Delphiniums from Messrs. Kelway & Sons, Langport, Somerset, made a very fine display. Notable varieties of the [illegible] [illegible] Edward VII. (deep violet, with white centre), Countess of Ilchester (pale blue and white), and John Thorpe.

A fine group of border Carnations in pots was exhibited by J. A. Young, Esq., [illegible] (gr. Mr. G. H. Street). The group [illegible] [illegible] selfs and yellow-ground [illegible] a few "Malmaisons." The plants [illegible] culture.

Messrs. Wallace & Co., [illegible] distributed a rock water garden [illegible] border flowers. [illegible] good Lilies in large groups, such as L. [illegible] and L. splendens, L. Henryi, L. Humboldtii, a

Fig. 17.—Rose Queen of Spain: flowers flesh-coloured, fading to cream. Obtained an Award of Merit at the Holland House Show (see p. 35).

fine mass of L. candidum, and many others. The Lilies were especially good and fresh-looking, and formed a feature of the exhibit; the Irises were also well shown, the rich colours of the Japanese kind were well seen amid the green of Bamboo and Eulalia and other similar things.

Water Lilies were very pretty and nicely grouped, while the rockery contained a choice assortment, notably of Calochorti.

Mr. M. FRICHARD, Christchurch Nurseries, Hants, contributed a brilliant display of hardy flowers, among which varieties of Japanese Irises (I. Kæmpferi) were most attractive. Some of the Delphiniums shown were of extra good quality, particularly the variety named "Magnificent." Alstrœmerias, Hemerocallis, Eremurus Bungei, and wonderful flowering growths of Ostrowskia magnifica were included amongst many other varieties of border flowers.

Mr. B. LADHAMS, 60, High Street, Shirley, Southampton, showed border flowers. The White Campanula alba coronata attracted attention. Hemerocallis Thunbergi, Armeria rubra, Centaurea Wiedmanni, Gaillardias (of many shades), and perpetual flowering Pinks, were all well shown.

MARY Countess of ILCHESTER, Abbotsbury Castle (gr. Mr. H. Kempshall), showed unusually fine flowering spikes of Phormium tenax, Beschorneria yuccoides, and Cordyline australis in a setting of Agaves, Aloes and other succulent plants.

Mr. W. J. GODFREY, Exmouth, Devon, showed Zonal Pelargoniums, Solanum Wendlandi, bunches of Roses and many vases of garden border flowers.

Messrs. BARR & SONS, King Street, Covent Garden, London, W.C., showed a choice array of hardy flowers. The group was arranged with taste, taller subjects being used as foils to smaller ones. Liliums, Delphiniums, Campanulas, Gladioli, Lupins, hardy Nymphæas, Salvias, Centaureas, &c., formed the principal subjects of the group.

Messrs. WARE also showed miscellaneous hardy flowers in season—Pæonies, Carnations, Delphiniums, Gaillardias, &c.

Messrs. JOHN PEED & SON, West Norwood, London, S.E., showed boxes and pans of Alpine and rock garden plants. The same firm also displayed a group of tuberous-rooting Begonias and excellent strains of Streptocarpus and Gloxinia.

Messrs. GEO. BUNYARD & Co., Maidstone, Kent, showed a large array of hardy border flowers. The large flowering Coreopsis lanceolata major was shown well; we also noticed a nice vase of Centaurea macrocephala. The double White Campanula Morbennii, Delphiniums in variety, Liliums, Irises, Œnotheras, and many other subjects contributed to a pleasing display.

Mr. J. BRADSHAW, Southgate (gr. Mr. Whitelegg), contributed a group of cut hardy flowers—Campanulas, Delphiniums, Lilies, Heucheras, and other things being shown in large numbers.

Messrs. HEATH & SON, Cheltenham, showed a mixed collection of garden flowers, including many Roses, Carnations, Sweet Peas, hardy border flowers, &c. The Roses were an especial feature of the group, many old favourites being presented in excellent condition.

Messrs. R. H. BATH & Co., The Floral Farms, Wisbech, displayed a similar group to the last-named exhibitor. They had Roses, Sweet Peas, and border flowers, the whole being backed by a row of showy spikes of Delphiniums. The new double blue Lobelia Kathleen Mallard found a place in this exhibit.

Messrs. WM. BULL & SONS, King's Road, Chelsea, showed vases of Gladioli, plants of the ornamental-leaved Hydrangea mivahs, and specimens of a new blue Lobelia—Bull's Compact Double.

Mr. R. C. NORCUTT, The Nursery, Woodbridge, displayed hardy garden flowers in great variety.

Mr. H. C. PULHAM, Elsenham, Essex, showed a temporised rock-garden furnished with appropriate plants. Campanula pumila and C. p. alba were splendidly shown.

The Misses HOPKINS, Mere, Knutsford, staged bunches of garden flowers and rock-garden plants.

The GUILDFORD HARDY PLANT NURSERY Co., Guildford, Surrey, showed border flowers in great variety. Lilium Brownii was represented by several good plants in pots. A large selection of Œnotheras was shown; spikes of Delphiniums were also prominent.

Messrs. WM. ARTINDALE & SON, Nether Green, Sheffield, showed hardy flowers, among which was a large number of Delphiniums and several shades of Iceland Poppies, one of orange colour being very pleasing.

Messrs. G. & A. CLARK, LTD., Dover, showed hardy plants in great variety, including Water Lilies, Japanese Irises, Eremuri, Dictamnus, Scabiosa Caucasica, Potentillas, and many other showy subjects. The same firm also staged a large assortment of Sweet Peas.

Hardy flowers in variety came from Messrs. PAUL & SON, Old Nurseries, Cheshunt. We noticed a fine batch of the old Siberian Larkspur Delphinium grandiflorum plenum—very rich in colour and most effective. Heucheras, Eryngiums, Campanulas, Alstrœmerias, and many examples of cut shrubs.

FERNS.

Displays of these plants were confined to two exhibitors, but each was worthy of the highest commendation.

Mr. H. B. MAY, Upper Edmonton, put up a large group, comprised entirely of choice sorts, all of which were beautifully grown. In Adiantums, A. macrophyllum bipinnatum, A. macrophyllum striatum, A. tetraphyllum acuminatum, and A. curvatum were specially good, while the beautiful A. lunulatum was never seen in better form. A. caudatum—another pretty species with drooping fronds—was equally good. The Aspleniums included cicutarium, the best forms of the bulbiferum type, and other choice sorts. Davallias were represented by all the choicest sorts. D. solida superba, which recently gained a First Class Certificate, was beautifully shown. Numerous varieties of D. fijiensis were specially good. D. braziliensis, a new introduction, is a beautiful species. D. Veitchii, D. retusa, and others were good. Nephrolepis were well shown, and included exaltata superba, a crested form which was recently given a First Class Certificate. N. Piersoni elegantissima recently gained a First Class Certificate, and is certainly one of the most beautiful of Ferns. Gymnogrammas included the best of the silver and gold forms in plain and crested varieties. Of Pteris there were P. Summersi, crested forms of P. cretica, P. scaberula, and others.

Messrs. HILL & SON, Lower Edmonton, arranged a beautiful group on the ground, with large specimens at the background and choice sorts in front. Tinted varieties are always a feature with this firm. Didymochlæna truncatula (with bronzy fronds), Davallia polyantha, Doodia aspera, multifida, Adiantum tinctum, A. Veitchii, A. macrophyllum, and A. Hendersoni gave colour to the group. Pteris Childsi, Pteris scaberula, Gleichenias, and Platyceriums were well shown in the best sorts. Davallia Fijiensis robusta, and several other varieties of the same species were good. Nephrolepis Fosteri, N. Piersoni, N. Scottii, and other sorts were well shown. Aspleniums included a beautiful specimen of A. præmorsum, Lygodiums in all the best species, Polypodiums on tree stems, Woodwardia radicans cristata, Aspidium lasercitiifolium, large Dicksonias, Alsophilas, Cibotiums, and other imposing species made up a very fine exhibit.

STOVE PLANTS.

Mr. W. ICETON, Granard Nurseries, Putney Park Lane, S.W., made an exhibit of Palms and other fine foliage plants; Hydrangea paniculata grandiflora, Lilies of the Valley worked up in the shape of columns, &c.

Messrs. J. LAING & SONS, Forest Hill Nurseries, London, S.E., made an exhibit of Caladiums, in which the plants were remarkable for good development of colour rather than large size. A new variety named King Haakon was especially pretty; the leaves are of rosy flesh and green shades.

Messrs. W. BULL & SONS, King's Road, Chelsea, exhibited a group of fine foliage plants, in the centre being a magnificent specimen of Dracæna Victoria. Tree Ferns, Nepenthes, Codiæums, Bougainvillea "Maud Chettleburgh" were all pretty and attractive.

Mr. L. R. RUSSELL, Richmond Nurseries, Richmond, had a corner exhibit in the large Orchid tent. It was composed of well-grown Abocasias, Codiæums, Cordylines, Palms, and other decorative foliage plants.

Mr. H. B. MAY, Upper Edmonton, displayed a beautiful batch of Ixoras. The varieties included I. macrothyrsa, with large trusses of bloom, I. Dixiana, one of the best kinds, with deep orange-coloured flowers, I. Williamsi, I. aurantiaca, I. Fraseri, I. amabilis, and others. Ixoras are now used by florists, and are found very serviceable. Mr. MAY has grown quite a large number for the market this season, and they have sold readily. Codiæums were also well shown, and a large collection of Zonal Pelargoniums (cut bloom), which included the most useful semi-double varieties grown for market purposes, also the best of the new Cactus-flowered varieties.

Messrs. JNO. PEED & SONS, Roupell Park Nurseries, West Norwood, showed a group of plants of Souvenir de la Malmaison Carnations, with a few Tree varieties in addition. From the same firm was exhibited an imposing group of Caladiums, most of them large specimen plants of brilliant colours.

MISCELLANEOUS PLANTS.

A group of Lisianthus eythropensis was shown by Miss ALICE DE ROTHSCHILD, Eythrop, Aylesbury (gr. Mr. E. Gibbs). The open salver-shaped blossoms are coloured violet, with dark base and gold anthers—an exceptionally fine flower.

Messrs. W. CUTBUSH & SONS, Highgate Nurseries, Middlesex, furnished one of the corners of the largest tent with "Malmaison" and Tree Carnations, hybrid Verbenas, Lantanas, Roses (Lady Gay, Mrs. F. W. Flight, and other varieties), Ferns, Palms, &c. Messrs. CUTBUSH'S style of arrangement of such groups at the Temple and other shows is well known, and the exhibit under notice was as effective as the best of them. Adjoining this group was an exhibit of rockery and water plants. Enclosed by the rockery was a small pool of water containing Nymphæas, &c.

Pæonies and tufted and fancy Pansies made a fine show as exhibited by Messrs. DOBBIE & Co., Rothesay, the last-named flowers being in superb form and in great variety. The same firm also contributed fancy and regal Pelargoniums and Sweet Peas.

Mr. G. F. WATERS, Deanland Road, Balcombe, Sussex, showed tree, border, and Souvenir de la Malmaison Carnations in popular varieties.

Mr. A. F. DUITON, Iver, Bucks, showed vases of American or winter-flowering Carnations in the newest and choicest varieties.

Messrs. HUGH LOW & Co., Bush Hill Park, Enfield, staged miscellaneous greenhouse flowering plants. They had a very fine display of the showy Solanum Wendlandi in small pots, Ericas in variety, Verbenas, Roses, Carnations, and pans of coloured Nymphæas.

Messrs. H. CANNELL & SONS, Swanley, displayed handsome Cannas, some of the spikes being not more than 6 inches high. Victory (scarlet and gold), Hesperides (pale orange), Niagara (crimson, with a golden edge), and Franz von Vecsey (cherry-cerise—quite a new shade in Cannas) are among the more distinct and novel. The same firm displayed a collection of Sweet Peas, the individual flowers as well as the trusses calling for admiration in such superb condition were they. Jeannie Gordon (cream and pink), King Edward VII., Emily Eckford (fine blue), Evelyn Byatt (a rich flame colour), and others formed an exceptionally fine lot.

Messrs. JOHN LAING & SONS, Forest Hill, showed Streptocarpi.

Messrs. J. CHEAL & SONS, Crawley, showed their new rose-coloured Lupine.

Messrs. PHILIP LADDS, Swanley, Kent, staged a white and yellow variety of market Chrysanthemum.

Mr. R. RASMUSSEN, Eastville Nurseries, Waltham Cross, exhibited a batch of bedding Petunias in small pots.

Messrs. JARMAN & Co., Chard, showed their new varieties of Sweet Sultans, vases of a yellow-coloured Carnation, and boxes of Roses, in which was seen a huge specimen of the variety Mildred Grant.

Mr. VINCENT SLADE, Taunton, Somerset, showed bunches of Zonal Pelargoniums.

Mr. JAS. DOUGLAS, Edenside, Great Bookham, exhibited border and "Malmaison" Carnations. The Nizam (a new tancy), Helen Countess of Radnor (dark clove colour), Viscountess Ebrington, new (buff yellow—a unique colour), Miss Willmott (of most perfect form), and Duchess of Wellington (heliotrope) are all good kinds.

Mr. T. A. HUMMERSTON, Epping, showed a new double pink Zonal Pelargonium named Pride of Essex.

Fuchsias and Zonal Pelargoniums were exhibited by Lady PHILLIMORE, Campden Hill, W. (gr. Mr. Becket).

AWARDS.

Begonia Miss May Sutton.—A very large flower with extra wide, shell-like petals opening somewhat loosely, of very pale pink colour with deeper rose at the margins. (Award of Merit.)

B. Purity.—This is a pure white variety of perfectly circular form, moderate size, and every petal crimped or crenated several times. It is the best flower we have seen of this type, and is very full in the centre. Both the varieties above were shown by Messrs. BLACKMORE and LANGDON. (Award of Merit.) See fig. 18.

Chrysanthemum maximum Mrs. Charles Lowthian Bell.—This is an extra fine variety of the type, the flowers being of unusual size. Shown by Mr. CHARLES DOWSON. (Award of Merit.)

Davallia elegans variety Mayi.—A variety with broad pinnules, and one having a fine effect. Shown by Mr. H. B. MAY. (Award of Merit.)

Lisianthus × eythropensis.—A group representing flowers of this reputed hybrid was shown by Miss ALICE ROTHSCHILD, Eythrop, Aylesbury (gr. Mr. Gibbs). The flowers of this greenhouse perennial plant are of deep purple colour, and very similar to those of the species L. Russellianus figured in these pages on September 1, 1888, p. 240. (Award of Merit.)

Pelargonium Hector Piacomelli.—This Ivy-leaved variety with semi-double, blush-mauve coloured flowers with red markings was shown by Messrs. R. & G. CUTHBERT. (Award of Merit.)

Nymphæa James Brydon, a rich crimson variety shown by Mr. AMOS PERRY. (Award of Merit.)

Richardia Mrs. Roosevelt.—This variety has moderately large sulphur-coloured spathes and maculated foliage. In appearance it would seem to be between R. hastata and R. Elliottiana. Shown by Mr. AMOS PERRY. (Award of Merit.)

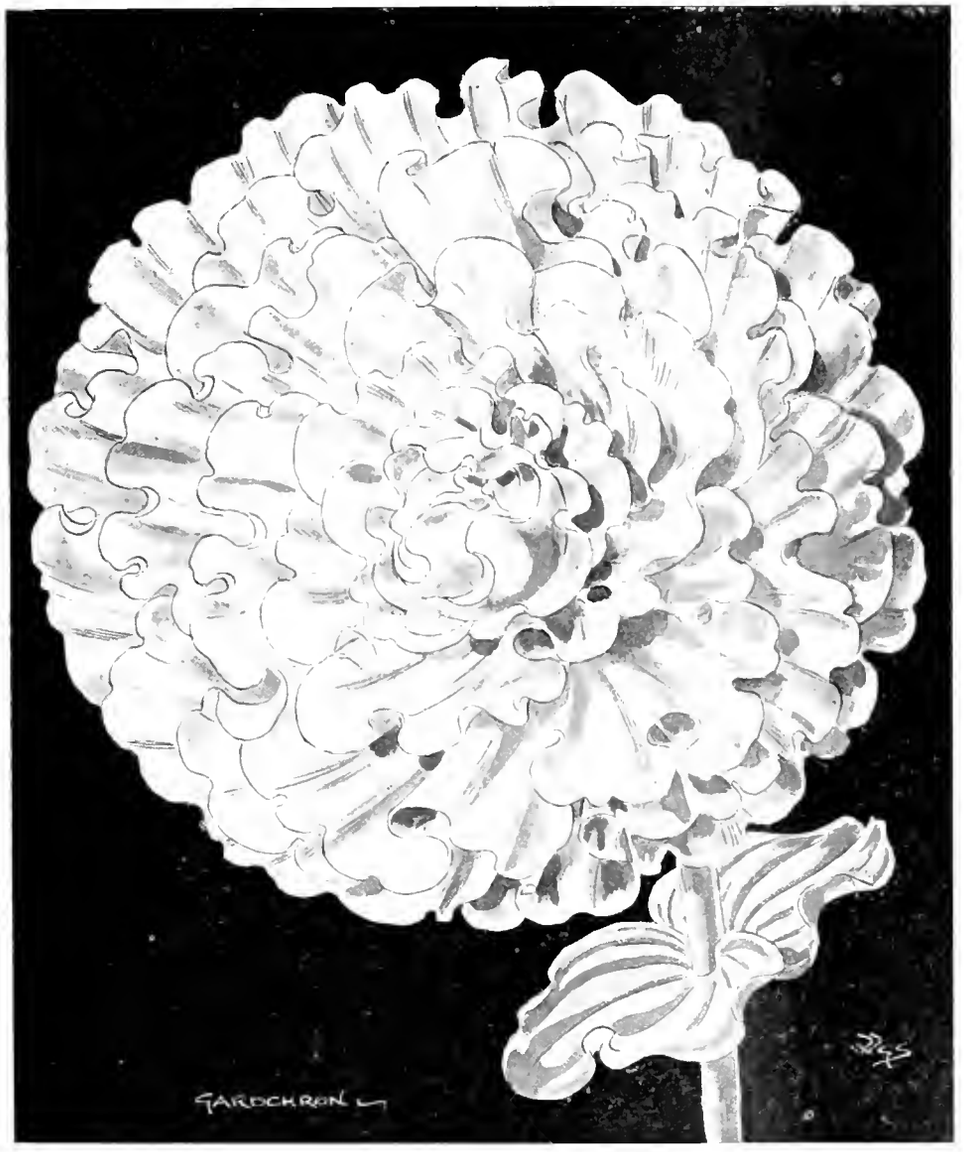

FIG. 18.—BEGONIA PURITY: FLOWER WHITE. OBTAINED AN AWARD OF MERIT AT THE HOLLAND HOUSE SHOW.

Osmunda Mayi.—This is a variety of O. palustris, with somewhat congested pinnules, having linear markings of creamy-white. Shown by Mr. H. B. MAY. (First-Class Certificate.)

Rose Queen of Spain.—A large H.T. variety, obtained as a seedling from Antoine Rivoire. The petals are of flesh colour, becoming paler and developing a little creamy shade as they become older. The blooms possess a large number of petals, and are thus in the florists' language "very full." Shown by Messrs. S. BIDE & SONS, Farnham, who had numerous specimens. A photograph of some of the flowers exhibited is reproduced at fig. 17. (Award of Merit.)

Rose Mrs. Jardine.—A H.T. variety having large shell-like petals of deep rose colour. Shown by Messrs. ALEX. DICKSON & SONS. (Award of Merit.)

Orchid Committee.

Present: Harry J. Veitch, Esq., in the chair, and Messrs. Jas. O'Brien (Hon. Sec.), F. Sander, W. Thompson, H. J. Chapman, H. A. Tracy, W. Boxall, De B. Crawshay, W. A. Bilney, H. Little, J. W. Potter, W. H. Young, W. H. White, T. W. Bond, A. A. McBean, W. Bolton, F. J. Thorne, W. Cobb, F. M. Ogilvie, Arthur Dye and H. T. Pitt.

In the main tent one side of the central staging was occupied entirely by Orchids, the first group, which commenced in front of the staging and extended a considerable distance, being staged by Messrs. F. SANDER & SONS, St. Albans. The back of the group was of graceful Palms, among which were arranged many finely-flowered specimens of Dendrobium Dalhousieanum, in the centre being an example of the feather-fronded Polypodium Knightii, over which trailed spikes of the large yellow Oncidium macranthum hastiferum. Arching forward were long sprays of Oncidium phymatochilum, Brassia verrucosa, and other species with slender sprays, and giving colour in the middle area were batches of the Sanderian strain of Lælio-Cattleya Martinetii, the variety Flambeau being of an intense reddish rose tint with purple lip, the same rich reddish hue suffusing several of the same section; a selection of Vanda Sanderiana with seven spikes of very fine flowers, and selections of Cattleya Mossiæ, including C. M. Glory, Fairy Queen, formosissima, Fascinator and Wageneri chrysoglossa, a fine white form with orange-coloured base to the lip. Odontoglossum amabile Royal Sovereign is like a large spotted O. crispum, with the large and long labellum indicating O. Harryanum in the purple marking at the base. The sepals and broader fringed petals were white with clusters of rose-purple flowers in the middle; Miltonia vexillaria, Hardy's variety of the M. v. rubellum section, with crimson mask at the base of the lip. Several specimens of the pure white Lælia majalis alba, a good specimen of a pale yellow variety of Masdevallia Harryana; several Lacæna bicolor, Sanders' variety, of Acineta-like growth, with long pendent racemes of cream-white flowers with purple labellums; several hybrid Odontoglossums; a very fine specimen of Epidendrum Medusæ, with many of its singular flowers. The plant has been in cultivation since 1882. Stanhopea Devoniana, and two other Stanhopeas, and Lælio-Cattleya Canhamiana Monarch, a very handsome and distinct variety, were also noticed. A conspicuous plant was a tall specimen of Vanda cærulea of Messrs. SANDER'S recent importation, which seems far superior to any previously imported. The inflorescence bore fine round flowers of large size and of white ground colour, the venation being followed by broad bands of a light violet hue.

JEREMIAH COLMAN, Esq., Gatton Park, Reigate (gr., Mr. W. P. Bound), furnished the next large group, which was excellently staged and embraced many exceptionally good Orchids. Prominent were the orange and scarlet colour of the clumps of Epidendrum Boundii; the trailing spikes of the large yellow Oncidium macrantham, of which there were about 140 feet of inflorescence; the showy flowers of Cattleya Warscewiczii, one specimen of which bore five grand flowers on a spike, and another, the variety Queen Alexandra, had the labellum almost entirely of a rich claret-crimson colour. Spathoglottis Colmani var. fulvissima, was the most beautiful of the Gatton Park hybrids of this Spathoglottis, and in which the large yellow flowers were spotted and tinged with reddish-rose over the whole surface except the tips of the sepals, which were of canary-yellow. Interesting plants in Mr. COLMAN'S group were several Dendrobiums MacCarthiæ with large rose and white flowers, that beautiful Ceylon species which puzzles most growers, but which Mr. BOUND succeeds with admirably; a nice selection of Odontoglossums, including the spotted O. crispum Boweyanum, &c., was also shown.

Messrs. CHARLESWORTH & Co., Heaton, Bradford, staged a group, which, in accordance with their usual custom, contained a selection of known good things and a few sterling novelties raised at their establishment. On the present occasion the best of the novelties was the new and pretty Odontoglossum × Eurydice (see Awards); others were a fine series of O. Rolfeæ, raised at Heaton, and which in beauty seem to eclipse the Continental form. The group contained a very interesting set of hybrids and fine varieties of species, those noted as of special worth being Sophro-Lælia læta Charlesworthii, a lovely dwarf

hybrid, with large reddish rose-coloured flowers; several plants of Lælio-Cattleya × Fire King, the noble reddish crimson variety, first shown by the late Mrs. R. Briggs-Bury; Miltonia vexillaria (Edippe and M. v. augusta, both very handsome; Brasso-Cattleya Digbyano-Mossiæ and several other hybrids of Brassavola Digbyana; a very fine form of Cattleya Lord Rothschild, of an intense rosy-crimson colour, and with greenish-gold veining on the lip, a form of Schomburgkia Thomsoniana, with good cream-white flowers with purple lips; Cymbidium Huttoni, the now rarer Miltonia Endresii, with many pretty white flowers marked with rose, a very fine batch of the large white Phalænopsis amabilis Rimestadtiana, which formed the centre of the group, and which is one of the finest of white flowers for cutting; Cypripedium "Daisy Barclay," the beautiful hybrid for which J. Gurney Fowler, Esq., formerly obtained a First Class Certificate; Cymbidium Huttoni and a large number of other rare Orchids.

Sir Frederick Wigan, Bart., Clare Lawn, East Sheen, Richmond (gr. Mr. W. H. Young), staged a small but very select group, including the handsome Cattleya Whitei, Wigan's variety, the unique Zygopetalum Roeblingianum, two good specimens of Platyclinis filiformis with many racemes of yellow flowers, Odontoglossum ardentissimum Joyce, a pretty variety with large white flowers formed much like those of O. Pescatorei, and with light violet blotches on the sepals and petals. Also in the group were two good forms of Dendrobium Phalænopsis, Miltonia vexillaria superba, Lælio-Cattleya eximia, some good Sobralias, Bulbophyllum Dearei and other rare species, for some of which see Awards.

Messrs. Hugh Low & Co., Enfield, staged an effective group in which were a very interesting series of Cattleya Gaskelliana, ranging from the pure white C. G. alba to the charming C. G. Mrs. Somerset Webb, a fine white flower tinged with lilac, and the handsome C. G. superba, as richly coloured as the general run of C. labiata. C. Warscewiczii, Low's variety, had finely coloured flowers, the usual yellow blotches on the lips being reduced to mere specks. The pretty Epidendrum prismatocarpum bore 21 fine spikes, and Lælio-Cattleya Canhamiana alba and other hybrids. Cypripedium niveum, Anguloa Clowesii, A. Ruckeri, Cattleya bicolor Grossii, Sobralia Wilsoni, C. Mossiæ Arnoldiana, Smee's variety, and other rare varieties were included in the group, which also contained some distinct forms of Odontoglossum Pescatorei, and Cattleya Mossiæ Edward Tack, a very finely formed flower of typical colour.

Major G. L. Holford, Westonbirt, Tetbury (gr. Mr. H. G. Alexander), showed a basket of six plants of Miltonia vexillaria, Hardy's variety, a form of M. v. superba of the M. v. rubella section, and with rose-pink flowers having a mask of crimson lines at the base of the lip, and a flower of Sobralia Sanderiana, a large form with white sepals and petals tinged with rose. The lip is of large size, and claret-coloured in front, yellow in the centre.

Monsieur A. A. Peeters, St. Gilles, Brussels, showed a fine specimen of the large pure white Cattleya Mrs. Myra Peeters (Gaskelliana alba × Warneri alba), one of the finest of white Cattleyas, and for which the Orchid Committee voted an Award of Merit, which the exhibitor refused to accept. Viewed by comparison with other awards given to white Cattleyas, the plant seemed to have been worthy of a First Class Certificate.

Francis Wellesley, Esq., Westfield (gr. Mr. Hopkins), sent Cattleya Gaskelliana Mrs. De B. Crawshay, a very pretty form of a uniform light rosy-lilac colour.

W. Thompson, Esq., Walton Grange (gr. Mr. Stevens), sent a fine plant of Odontoglossum Crawshayanum, Walton Grange variety, with a fine inflorescence of very large flowers.

AWARDS.

First Class Certificate.

Cypripedium callo-Rothschildianum, from J. Gurney Fowler, Esq., Glebelands, South Woodford (gr. Mr. J. Davis). The splendidly grown plant as exhibited, with two strong spikes, each of three large and handsome flowers, represented the finest hybrid of C. Rothschildianum yet seen. The large dorsal sepal was greenish-white, closely lined with chocolate purple, the broad petal cream-white, with closely arranged blotched lines of claret-purple, and the large labellum reddish-brown.

Cypripedium Godefroyæ leucochilum Hodgkinsoni, from Messrs. Sander & Son, St. Albans. A remarkable variation, equal in size and in the thick substance of the flower to C. bellatulum. The broad sepals and petals were sulphur-yellow, the veining being claret-purple; the large labellum cream-white, unspotted except on the inside (fig. 16, p. 32).

Cattleya Warscewiczii "*White Queen*," from W. P. Burkinshaw, Esq., Hessle, Hull. The "white gigas" for which Mr. Burkinshaw received an Award of Merit August 4, 1903. Flowers pure white, with the rose lip of typical C. Warscewiczii.

Bulbophyllum crassens, from Sir Frederick Wigan, Bart., Clare Lawn, East Sheen (gr. Mr. W. H. Young). A noble Malayan species allied to B. Pahudi and B. Ericssoni. The plant bore monophyllous oblong pseudo-bulbs and an erect umbel of eight flowers, each extending over 6 inches across the sepals, which, with the narrow petals, were whitish veined with pale-green, the face of the column and the hinged labellum being tinged with rose-colour.

Award of Merit.

Brasso-Cattleya Madame Hye (C. Harrisoniana × B. Digbyana), from Major G. L. Holford, C.I.E., C.V.O., Westonbirt, Tetbury (gr. Mr. H. G. Alexander). A pretty novelty and the first cross effected between B. Digbyana and the slender-bulbed Cattleyas, flowers in shape indicating C. Harrisoniana, blush-rose, with distinctly three-lobed labellum, which is fringed, pale-rose in front, disc light-yellow.

Aerides virens Sanderæ, from Messrs. Sander & Sons, St. Albans. The first albino of this pretty and floriferous species. Flowers in racemes, pure white.

Brasso-Cattleya striata splendidissima (B. fragrans × C. Mossiæ), from Messrs. Sander & Sons. A pretty and fragrant white flower, in which the large labellum is the prominent feature, and which has an orange disc and pale rose apex.

Odontoglossum Eurydice (hastilabium × cirrosum), from Messrs. Charlesworth & Co., Heaton, Bradford. A remarkable cross, with excellent results, the best characters of the species being brought out in a short inflorescence. Sepals and petals lanceolate, whitish, with numerous red-brown bars on the inner two-thirds. Lip constricted in the middle, the base yellowish, tinged with brown, the front lobe blush white.

Cattleya F. W. Wigan, Goodson's variety (Schilleriana × Dowiana aurea), from H. S. Goodson, Esq., Fairlawn, West Hill, Putney (gr. Mr. G. E. Day). A very handsome hybrid of the form of C. Schilleriana, sepals and petals whitish, tinged with purple, lip veined with rose-crimson.

Odontoglossum grande, Zandaghe variety, from Gustave H. Muller, Esq., Rotterdam. A singular and showy variety, with the lip of typical O. grande, but with a suspicion of O. Schleiperianum in the general aspect of the flower, which approaches O. Wilhamsianum, which might be a hybrid of the other two species named. Sepals yellow, barred with brown; petals broad yellow, barred with brown on the inner halves; lip whitish with brown bars at the base.

Botanical Certificate.

Hemipilia amethystina, from Sir Frederick Wigan, Bart. (gr. Mr. W. H. Young). A singular terrestrial Orchid, with a single roundish variegated leaf, and an erect inflorescence of rose flowers with amethyst purple lip.

Fruit and Vegetables.

A superb collection of fruit trees in pots, numbering some 40, and making a singularly attractive group, was staged at one end of a tent by Messrs. Thos. Rivers & Sons, Sawbridgeworth. The collection included Peaches, Nectarines, and Cherries. Some of these latter, 12 years old, stood 10 feet in height, and some Peaches 8 feet in height. All the trees were finely fruited, the Peaches especially being large and well coloured. The whole represented a triumph in pot-tree culture. The Peaches included Sea Eagle, Duke of York, Princess of Wales, Peregrine, and Thos. Rivers. The Nectarines were Early Rivers and Victoria. The Cherries comprised Empress Eugenie, May Duke, Early Rivers, Black Bigarreau, Frogmore Bigarreau, and Emperor Francis.

A smaller, but excellent, lot of trees, 18 in number, were staged by S. Heilbut, Esq., Maidenhead (gr. Mr. G. Camp). Of Nectarines, six fine trees being present, Early Rivers was the chief, the fruits large and well coloured. Peaches included Peregrine, Duchess of Cornwall, Hale's Early, Early Rivers, Elton, Black Bigarreau, Emperor Francis, Bigarreau Napoleon, and B. Noir de Guben. Messrs. G. Bunyard & Sons, Maidstone, had a large collection of pot trees of lesser size and more varied. In this group were Cherries, Apples, Peaches, Plums, and other fruits. The trees were well fruited, and served to show what a remarkable variety could thus be obtained in a comparatively limited space. Most of the trees were quite young.

Collections of Fruit.

Of very high merit, showing first-class culture, was the collection of Pineapples and Strawberries shown by the Right Hon. Lord Llangattock, The Hendre, Monmouth (gr. Mr. T. Coomber). There were 17 handsome Queen Pines, all of perfect form, dishes of Raymaker and Barrington Peaches, a seedling Melon, and the finest samples in the show of Strawberries—Gunton Park, Trafalgar, The Laxton, Bedfordshire Champion, Leader, The Bedford, Sir Charles Napier, and Fillbasket. These were displayed in shallow boxes in a most attractive way. Messrs. W. May & Co., Teynham, Kent, set up a most interesting collection of 36 dishes of Cherries, the fruits very fine samples. The finest whites were Bigarreau Napoleon, Alton Heart, Florence Heart, and Amber Heart. The best blacks were Black Eagle, Waterloo, Webb's Improved Black, Turkey Heart, and Bedfordshire Black Heart.

C. C. Paine, Esq., Haverstock Hill (gr. H. Whiting), sent nine bunches, berries large and finely finished, of Black Hamburgh grapes, and some Melons.

From the Horticultural College, Swanley, Kent, came numerous very fine Melons, richly coloured and handsomely netted, named College seedling; also three baskets of Dymond Peaches.

Lord Hillingdon, Uxbridge (gr. Mr. A. R. Allan), sent fine Strawberries in variety, Gunton Park, Lady Suffield, Lord Suffield, Trafalgar, Waterloo, Dr. Hogg, President, Sir J. Paxton, and others, several varieties showing singularly deep colour.

Messrs. George Bunyard & Co. had a most interesting collection in dishes and boxes of Peaches, Waterloo and Alexander, Cherries, Kentish Black, Ludwig Bigarreau, Elton Heart, Bigarreau Napoleon, Emperor Francis, Florence, St. Margarets, Windsor, Noir de Guben, Waterloo, and Noble. Also yellow and red Raspberries, various well-preserved Apples, and a large variety of Strawberries, including Louis Gauthier, Givon's Late Prolific, Latest of All, British Queen, The Bedford, Dr. Hogg, and Royal Sovereign.

Vegetables.

Of these products, Peas were the dominant feature, Messrs. Jas. Carter & Co., High Holborn, having staged probably the largest collection seen at any similar exhibition. There were not fewer than 250 dishes, and all diversely named. The collection included the very finest and newest variety in "Quite Content," with pods 6 to 7 inches long; and samples of those now regarded as quite old. Also there were first earlies, the pods quite ripe, and such late ones as Carter's Michaelmas and Sutton's Late Queen were stats; yet all raised from one sowing. Of the finest pods, besides Quite Content, were Duke of Albany, Alderman, Gladstone, Duchess, Rent-Payer, Standard, Captain Cuttle, Stratagem, and others. The firm also exhibited a large collection of Cos and Cabbage Lettuces.

Miss M. A. Lodge, Loosley Park, Guildford (gr. Mr. R. Stannard), sent 12 varieties of seedling Peas, many evidently very fine and meriting attention, being specially great croppers.

Exhibits in the Open.

Mr. D. Russell, of the Essex Nurseries, Brentwood, showed extensively variegated and other pictorial shrubs and trees, and a welcome bit of bright colour was imparted to the group by a score of Canna in flower. Of novelties we may mention Ulmus minor foliis variegatis, Aralia pentaphylla, and the yellow-foliaged variety of Cupressus macrocarpa, and a plant 3 feet high of Veronica Traversi conspicuous for its extreme floriferousness.

Mr. L. R. Russell, of the Richmond Nurseries, Richmond, Surrey, showed a group of

similar plants, but placed widely apart, so as to show them to better advantage. These consisted largely of forms of Hedera, both variegated and green-leaved, Dimorphanthus, Eleagnus macrophylla, Cistus ladaniferus, and Ceanothus Gloire de Versailles. The group was backed with purple Beech and Prunus Pissardi.

Messrs. W. FROMOW & SONS, Sutton Court Nurseries, Chiswick, arranged a large group of pictorial trees and shrubs consisting of Japanese Acers in great variety, the entire group being bordered with a line of Arundinaria Fortunei variegata and Eurya latifolia variegata.

Messrs. J. CHEAL & SONS, Lowfield Nurseries, Crawley, showed numerous specimens of Veronica Autumn Glory, and V. Blue Gem, the former with deep blue, and the latter with light blue flowers. There were also examples of Catalpa syringæfolia, aurea, Abies pungens glauca, Clematis erecta alba, and several other varieties.

Messrs. W. CUTBUSH & SON, Highgate and Barnet, showed, as usual, a large assortment of Topiary objects, which must have cost infinite trouble to form and keep in shape.

Pigmy trees were shown by Messrs. CARTER, of High Holborn, and by Messrs. BARR & SONS, King Street, Covent Garden, London.

Mr. AMOS PERRY, Hardy Plant Farm, Winchmore Hill, had a showy group of hardy herbaceous cut blooms of choice species and varieties, including Heuchera sanguinea, H. s. Walker's variety, Perry's variety of Phlox Laphami (a distinct, blue-flowered variety), a number of showy Turk's Lilies, such as L. pardalinum, L. pardalinum, Red Giant, the scarlet L. dalmaticum, and others. A number of big bunches of Delphiniums in variety were shown.

An extensive exhibit of Cabbage and Cos varieties of Lettuces was contributed by Messrs. CARTERS, High Holborn, London, of which, although most of them were in the best state for consumption, nothing in the way of novelties was observed, with the exception of Holzschuhe's Success, a brown-leaved Cabbage variety, New York Peerless, with red spotted leaves, and Jumbo Giant White Cos. The same firm showed a number of well-flowered plants of their new double-flowered blue Lobelia, excellent as a basket plant, as which it was shown.

HORTICULTURAL SUNDRIES, IMPLEMENTS, &C.

The POTTERS' ART GUILD (Mrs. F. G. Watts' Village Industry), Compton, Guildford, exhibited vases, ornamental pots of quite new forms in modern pottery, and square and circular receptacles for plants, a wellhead, &c., all but the last being manufactured from a fine kind of red clay. Garden seats were displayed by Mr. CASTLE, Baltic Wharf, Millbank, London, made of unpainted Oak, ship timber, massive and endurable; vases, plant tubs and sundials from Messrs. PULHAM & SON, 71, Newman Street, London, W.; motor and hand mowing machines by Messrs. GREEN & SONS—a very old-established firm of makers. Messrs. RANSOME & SIMS were likewise exhibitors of motor mowers.

Messrs. CHAMPION & CO., Old Street, City Road, showed handsome plant tubs of polished Oak. Messrs. LIBERTY & CO., Regent Street, W., showed vases, pedestal, window-boxes, bordering for flower beds, sun-dials, and basin and fountain in terra cotta: Messrs. D. ROBERTS & SON, Tottenham, London, N., had plant tubs for indoor and outdoor uses. Models of glass-houses, &c., were shown by Messrs. DUNCAN TUCKER & SONS, of Tottenham, showing light, yet strong, construction and ample means of ventilation: Messrs. SKINNER, BOARD, & CO., Rupert Street, Bristol, showed an amateur's glass-house, furnished with plant benches of corrugated iron sheeting.

Garden seats, summer-houses of canvas, and garden hose on reels were shown by Messrs. HEADLEY & EDWARDS, LTD., Cambridge, who also had specimens of plant-vases constructed with light iron ribs; the interiors to be lined with fine turf, which keeps alive and is kept cut close with the shears.

Messrs. W. POORE & CO., 52, Queen Victoria Street, showed American stoves and the Challenge hot-water apparatus for heating glass-houses and other structures. Messrs. TABOR & CO., Dunedin House, Basinghall Avenue, E.C., showed samples of their Fertiliser. The Italian firm, "MANUFACTURA DE SIGNA," of Florence—London address, 17, Mount Street, W.—exhibited garden seats, vases, plant tubs of antique design in a sort of light-coloured terracotta. Mr. D. G. CORNWALL, Warwick Gardens, Worthing, showed his very convenient form of fruit-packing baskets for transit by rail or post. A combined tray and table, with folding-up legs, came from Messrs. ABBOTT BROS., and fine soft spongy peat for Orchids and stove plants, and painted and polished Oaken tubs were shown by Mr. J. DOX, of Park Row, Nottingham.

Messrs. W. WOOD & SON, of Wood Green, London, showed manures, sprayers, weed killers, garden tools, and appliances, insecticides, soil in variety, fruit-packing boxes—a very large exhibit.

Gishurst compound and preparations for the destruction of insects came from PRICE PATENT CANDLE CO., Battersea; and Mr. J. GEORGE, 14, Redgrave Road, Putney, had a small exhibit of manures, soils, insecticides, and mushroom spawn. Messrs. MERRYWEATHER & SONS showed a number of their specialities applicable to uses in gardens; and OLLENDORFFS, 15, Leadenhall Street, London, showed manures for special purposes, Peruvian Guano, as did Messrs. W. VOSS & CO., Carlton Works, Glengall Road, Millwall, London, including their "Wonderful," a soluble powder manure of excellent quality, and green sulphur, a French product of extreme fineness that can be used with a small pair of bellows against microscopical moulds and other fungi. Slugene, the best substance for the destruction of slugs, was shown by Messrs. STANLEY & CO., LTD., 69, Fenchurch Street, London. Mr. J. WILLIAMS, 41, Oxford Street, Ealing, showed pretty glass devices as flower-holders for dinner table decorations.

Messrs. CORRY & CO., Shad Thames, London, S.E., exhibited insecticides, plant cleansers, and manures in great variety. Messrs. RANSOME, SIMS, & JEFFERIES, Ipswich, had hand and horse mowing machines.

Knapsack and other sprayers, insecticides, syringes, &c., were shown by DE LUZY FRERES, 99, Lilford Road, Camberwell. Mr. G. W. RILEY, Norwood Road, Herne Hill, S.E., made a very extensive show of summer-houses, one being of circular shape and mounted on a turntable, so as to be capable of being readily turned in any desired direction. In all cases the woodwork was polished and varnished, and the front parts were constructed of barked oak.

AWARDS MADE BY THE COUNCIL.

SHERWOOD CUP:—H. B. May, for pot plants.

GOLD MEDALS:—W. Cutbush & Sons, for a group of plants; Lord Llangattock, for fruits; T. Rivers & Sons, for fruit trees in pots; Sander & Sons, for Orchids; H. B. May, for Ferns, &c.

SILVER CUPS:—G. Bunyard & Co., for fruits and flowers; G. Paul & Son, for Roses and herbaceous plants; J. Carter & Co., for Peas, &c.; J. Peed & Son, for Caladiums, &c.; L. R. Russell, for ornamental trees, &c.; T. S. Ware, Ltd., for Begonias, &c.; J. Jackman & Sons, for Roses, &c.; Wm. Paul & Son, for Roses; W. Wallace & Co., for hardy plants; J. Hill & Son, for Ferns; Frank Cant, for Roses; S. Heilbut, Esq., for fruit trees in pots; Amos Perry, for hardy plants, &c.; Charlesworth & Co., for Orchids; M. Pritchard, for herbaceous plants, &c.; Blackmore & Langdon, for Begonias; Jeremiah Colman, Esq., for Orchids; Gunn & Sons, for Phloxes; Sir F. Wigan, for Orchids; E. R. Cant & Sons, for Roses; J. Bradshaw, Esq., for hardy Peas; R. & G. Cuthbert, for greenhouse plants.

SILVER GILT FLORA MEDALS:—Barr & Sons, for hardy plants; J. Cheal & Son, for trees and shrubs; W. Bull & Son, for stove and other plants; H. Cannell & Sons, for Cannas, &c.; G. Reuthe, for herbaceous plants; C. W. Breadmore, for Sweet Peas, &c.; Dobbie & Co., for Violas, &c.; Hugh Low & Co., for Orchids, &c.; J. Forbes, for Pentstemons, &c.

SILVER GILT BANKSIAN MEDALS:—J. Laing & Sons, for Caladiums, &c.; R. H. Bath & Co., for Roses, Carnations, &c.; A. F. Dutton, for Carnations; W. Fromow & Sons, for Maples, &c.; Hobbies, Ltd., for Roses; G. & A. Clark, Ltd., for herbaceous plants; G. Cooling & Sons, for Roses; A. Dickson, for Roses; W. Iceton, for foliage plants; Kelway & Son, for herbaceous plants; King's Acre Nursery Co., for Roses.

SILVER FLORA MEDALS:—H. Eckford, for Sweet Peas; Ladhams, Ltd., for herbaceous plants; D. Russell, for shrubs; R. C. Notcutt, for hardy plants; A. Ll. Gwillim, for Begonias; C. F. Waters, for Carnations; Jarman & Co., for Sweet Sultans; J. Douglas, for Carnations; E. E. Grimson, Esq., for Roses; Lady Phillimore, for Fuchsias; Mary Countess of Ilchester, for semi-tropical plants; W. J. Godfrey, for Solanum Wendlandi, &c.; J. A. Young, Esq., for Carnations; W. Artingdale & Son, for herbaceous plants; G. Stark & Son, for Sweet Peas.

SILVER KNIGHTIAN MEDALS:—Messrs. Ray, for Cherries.

SILVER BANKSIAN MEDALS:—C. C. Paine, Esq., for Grapes; Swanley College, for Melons; J. King & Son, for Sweet Peas; E. Mocatta, Esq., for Sweet Peas; W. Poupart, for Sweet Peas; H. C. Pulham, for Alpines; Misses Hopkins, for Alpines; Heath & Son, for miscellaneous plants; A. J. Upton, for Alpines; W. & J. Brown, for miscellaneous plants; V. Slade, for Pelargoniums.

HORTICULTURAL SUNDRIES, IMPLEMENTS, &C.

SILVER-GILT BANKSIAN:—Manifattura di Signa, for terra cotta vases.

SILVER KNIGHTIAN:—G. W. Riley, for rustic summer-houses; A. Shanks & Son, for lawn mowers; W. Duncan Tucker, for greenhouses; Merryweather & Sons, spraying apparatus; D. G. Cornwell, fruit-packing boxes.

SILVER BANKSIAN:—Wood & Sons, for horticultural sundries; Pulham & Sons, for rockwork; Ransomes, Sims and Jefferies, for lawn mowers, &c.; Potters' Art Guild, for terra cotta garden furniture; Philip Castle, for garden seats and tables; T. Green & Son, for lawn mowers; Headley & Edwards, for garden furniture.

BRONZE BANKSIAN:—Geo. James, Herbert & Co., and J. Bentley, for horticultural sundries; Champion & Co., for tubs for shrubs; Liberty & Co., for terra cotta vases, &c.; Abbott Bros., for table trays and preserving bottles; Dowell & Son, for Orchid pottery; J. Pinches, for Acme labels.

SWEET PEAS AND VIOLAS AT WISLEY.

ON July 6 a deputation from the Floral Committee, with Mr. W. Marshall, chairman, visited Wisley to inspect the Sweet Peas and Violas then in flower. The trial of Violas is in reality the continuation of a trial which commenced last year, therefore awards had already been made to some of the best varieties. On the occasion under notice three marks were awarded to Viola Maggie Mott, which is certainly a very good flower, and distinct amongst the pale-blue Violas of the type of Kitty Bell and Dorothy. It was agreed that Royal Sovereign was the best yellow variety, and that King Cup and Jennie are identical, but are not so rich in colour as Royal Sovereign. White Empress was the best white variety present, but Marchioness was considered to be synonymous with this. Archie Grant was the best dark-blue flower, but Councillor Watters had a better habit of growth, was more floriferous, its flowers, however, are rather purple than blue.

The trial of Sweet Peas could hardly be considered satisfactory for two reasons: the first is that the seeds, as supplied by the nurserymen and seedsmen, were in many cases very untrue to name, some varieties containing almost as many "rogues" as true flowers. The second reason is that there were not sufficient varieties cultivated to allow of the new ones being judged in comparison with older sorts of the same type, which in all cases of florists' flowers, fruits, and vegetables is very desirable. Three marks were awarded to each of the following varieties, which have already been described in these columns. Countess Spencer (light rose colour), John Ingman (reddish-rose), the Hon. Mrs. Kenyon (sulphur coloured), Mrs. G. Higginson (pale blue or mauve), Dainty (white, very faintly tinted), Jeannie Gordon (pink and white), Helen Pierce (pale blue), Dorothy Eckford (white), and Helen Lewis (rose coloured). One of the most distinct varieties is Helen Pierce, the pale blue standard being marked with deeper coloured wave-like veining. Scarlet Gem was one of the least true varieties, and many of the seeds of Mrs. Chas. Foster failed to grow.

NATIONAL SWEET PEA.

JULY 5.—We were enabled to publish a report of the principal classes of this show, which was in progress as we wrote, in our last issue, and we now print further details.

Eighteen bunches, distinct.—Among three good exhibits, that staged by Mr. T. VICKERS, Well Vale, was awarded the first prize.

Twelve varieties, distinct.—Mr. CHAS. BREADMORE was followed in this class by Messrs. SALTMARSH, The Nurseries, Chelmsford.

Nine bunches of Sweet Peas, distinct.—Thirty-seven displays were seen in this class. The premier collection came from Mr. H. W. LEES, Warblington Cottage, Havant.

Six bunches in distinct varieties.—The best display among twenty-four was that shown by Dr. LAMPLOUGH, Kirstall, Alverston.

SPECIAL COLOUR CLASSES.

The following is a list of the varieties and prize winners in the classes for bunches of Sweet Peas of scheduled colours:—White: Dorothy Eckford, shown by Dr. LAMPLOUGH. Blush: Duchess of Sutherland, shown by Messrs. PROCTER, Carnforth. Crimson: King Edward VII., shown by Mr. T. HITCHIN, Trevarrick, Cornwall. Cerise: Coccinea, shown by the last-named exhibitor. Rose and carmine: Lord Rosebery, shown by Mr. M. Y. GREEN, Eynsford. Pink: Gladys Unwin. Orange: Miss Willmott, shown by Mr. C. BREADMORE. Yellow and buff: Hon. Mrs. Kenyon, shown by Mrs. F. BREWER, Richmond, Surrey. Lavender: Lady Grisel Hamilton, shown by Messrs. G. & A. CLARK, LTD., Dover. Blue: Romolo Piazzani, shown by Mr. C. W. BREADMORE. Mauve: Mrs. W. Wright, shown by Dr. LAMPLOUGH. Violet and purple: Duke of Westminster, shown by Mr. C. W. BREADMORE. Maroon and bronze: Black Knight, shown by Mr. G. CRABBE, Addlestone, Surrey. Magenta: George Gordon, shown by Messrs. G. & A. CLARK, LTD. Picotee edged: Lottie Eckford, shown by Mr. F. ACKLAND, Frome. Striped and flaked red and rose: America, shown by Mr. E. F. USHER (gr. to C. K. Wild, Esq.), New Eltham. Striped and flaked purple and blue: Princess of Wales, shown by Mr. F. ACKLAND. Bicolour: Triumph, shown by Messrs. CLARK. Fancy: Agnes Johnstone, shown by Mr. BREADMORE.

NEW VARIETIES.

With a view to encourage the exhibition of newer varieties of Sweet Peas, the colour classes were duplicated for varieties introduced in or since 1901, and which were not in the society's classification table. No award was given unless the variety showed distinctness from or superiority to those already in cultivation. In many of the classes no awards were given, but they were in those following:—Blush: Bobby K., shown by Mr. CHANDLER, Haslemere. Crimson: Queen Alexandra, shown by Messrs. J. HOUSE & SON, Westbury-on-Trym. Lavender: Lord Nelson, also shown by Messrs. HOUSE. Blue: Bolton's Blue, shown by Mr. H. ALDERSEY, Chester. Violet and purple: Mrs. M. Gerhold, shown by Mr. H. A. GERHOLD, Penarth. Striped and flaked purple and blue: Helen Pierce, shown by Mr. F. R. CASILE, Brunscombe, Oxford.

AWARDS TO NOVELTIES.

Sweet Pea Audrey Crier.—The society offered a silver medal for the finest novelty shown. This was secured by Mr. C. W. BREADMORE for his variety Audrey Crier; in addition a first class certificate was awarded to it. The flower greatly resembles Gladys Unwin, but the colour is much brighter, due to the deeper suffusion of rose. The standard is very large and somewhat reflexed, forming with the wings a very handsome bloom.

Awards of merit were awarded the following new varieties:—

Princess Maud of Wales.—A very handsome and brightly-coloured variety of salmon-pink shade, the well-formed and large standard being deeper coloured along its centre; the wings are paler than the standard, and the keel is white.

Maud Guest.—This variety is white, faintly flushed with mauve. The standard is large, and has a wavy margin. The suffrescence is developed on tall, stiff stems.

Horace Wright.—A fine, dark-blue coloured flower, almost purple. A useful addition to the dark coloured section. The above three varieties from Mr. H. ECKFORD, Wem.

Dora Cowper.—A not over-large flower of yellow and buff shades. Three flowers are seen in most cases on the peduncle.

Etta Dyke.—A very handsome white flower, said to be a sport from the well-known Countess Spencer, which variety it much resembles in form.

Elsie Herbert.—Said to be a cross between Dorothy Eckford and George Herbert. It is a large flower, with white ground suffused with faint rose. The standard is very large. The above three were shown by Mr. C. W. BREADMORE.

Queen of Norway.—A lavender-coloured flower of much merit, all the parts being large, especially the standard, which is wavy in outline. Three pips are seen on the truss. Shown by Mr. BOLTON.

NON-COMPETITIVE EXHIBITS.

Non-competitive displays of Sweet Peas were staged by the following exhibitors:—Messrs. R. H. Bath, Ltd., Wisbech (Silver Medal); Messrs. Cant & Sons, Swanley (Gold Medal); Messrs. Bakers, Wolverhampton (Gold Medal); Miss H. Hemus, Holdfast Hall, Upton-on-Thames (Silver-Gilt Medal); Messrs. Gilbert & Sons, Bourne, Lincolnshire (Silver Medal); Messrs. Carter & Sons, Ltd., Holborn (Silver-Gilt Medal); Messrs. Dobbie & Co., Rothesay (Gold Medal); Mr. Robert Sydenham, Birmingham (Silver Medal); Messrs. E. W. King & Co., Coggeshall (Silver Medal); Mr. J. Williams, Oxford Road, Ealing (Silver Medal); Mr. Robert Bolton, Warton, Carnforth, an unique arrangement of baskets of Sweet Peas in the form of an arch, with other baskets suspended; one of the prettiest exhibits in the show (Gold Medal); Mr. C. W. Breadmore, Winchester (Gold Medal); Messrs. G. Stark & Son, Great Ryburgh (Silver-Gilt Medal); Mr. H. Eckford, Wem (Gold Medal); Messrs. G. & A. Clark, Dover (Silver-Gilt Medal); and Mr. W. J. Unwin, Histon, Cambs. (Gold Medal).

CROYDON HORTICULTURAL.

JULY 4.—The thirty-ninth summer exhibition of this society was held on the above date in the grounds of Brickwood House, Addiscombe Road.

ROSES.

OPEN CLASSES.

There was seen a moderately large display of blooms, but the unfavourable weather prevailing when the plants started to grow seems to have had an injurious effect on the earlier flowers.

Twenty-four Roses, distinct.—This was a nurserymen's class, and the winner of the 1st prize was Mr. F. J. JEFFERIES, Rose grower, of West Croydon, who had in his exhibit capital blooms of Marchioness of Dufferin, Mrs. J. Laing, Mildred Grant, Capt. Hayward and Mrs. Sharman Crawford; 2nd, Mr. T. BUTCHER, who had especially good blooms of Ulrich Brunner, Etienne Levet and Marie Baumann.

The class for 12 Roses, of one variety, brought a creditable box of blooms from Mr. F. J. JEFFERIES.

Challenge Cup.—A Challenge Cup or Bowl Competition was open to Amateurs for 36 Roses in distinct varieties. The 1st prize fell to E. M. EVERSFIELD, Esq., Denne Park, Horsham, and it was noticeable that the Roses from the heavier soils of Sussex were finer and of more substance than those from off the lighter soils round Croydon and Reigate. The winning stand contained good blooms of Ulrich Brunner, Mad. G. Luizette, Mildred Grant, Alice Lindsell, &c.; 2nd, Mr. J. Salter (gr. to Mrs. HAYWOOD, Woodhatch Lodge, Reigate).

Twenty-four Roses, distinct.—Mrs. HAYWOOD was 1st here, the better blooms being Heinrich Schultheis, Mad. G. Luizette, Tom Wood, Florence Pemberton, and Marie Baumann, the same almost as those that secured her the second prize in the previously noticed class. 2nd, A. MORRIS, Esq.

Six Roses, distinct.—E. J. HOLLAND, Esq., Silverhall, Grange Road, Sutton, won the 1st prize. A bloom of Mildred Grant in this exhibit received the award of a Silver Medal.

Mr. E. M. EVERSFIELD was 1st for 12 Roses of one variety with Bessie Brown.

GROUP OF PLANTS ARRANGED FOR EFFECT.

The space allowed was a semi-circle measuring 17 feet × 10 feet: the 1st prize was awarded to Mr. Phillips (gr. to Col. R. W. INGLIS, Craigendowie, Reigate), with a pleasing arrangement of Codiæums, Caladiums, Odontoglossum crispum, Dendrobiums, Cattleyas, &c., in a setting of Adiantum, &c.; 2nd, Mr. C. Lane (gr. to E. H. COLES, Esq., Burntwood, Caterham), with a much more profuse display of flowering plants.

In the similar smaller class for a group of plants occupying an area of 7 feet × 6 feet, Mr. C. Brooks (gr. to Dr. St. G. C. REID, Brigstock House, Thornton Heath) won the 1st prize. The group contained many small flowering and foliage plants backed with tall Aralia Sieboldi, &c.

Group of Caladiums.—1st, Mr. J. Hale (gr. to F. LINK, Esq., Homedale Park, Hill Road, Croydon). Small plants to which the exhibitor, by crowding them together, had not done full justice.

Gloxinias were nicely shown by Mr. J. Lowry (gr. to Miss BLAKE, Duppas Hill Terrace, Croydon).

In the class for nine Ferns the 1st prize went to Mr. F. Bishop (gr. to E. D. MORTON, Esq., Bagbie House, Croydon). They were nice specimens in 6-inch pots.

Mr. F. BISHOP was also 1st for a group of Begonias; 2nd, Mr. E. Paxted (gr. to S. TAYLOR, Esq., Bramley Hill Side), Croydon.

The best six Fuchsias, averaging 3 feet in height, came from Mr. G. EDWARDS, Windmill Cottages, Shirley.

A class was provided for three flowering and three ornamental foliage greenhouse plants. The 1st prize was taken by Mr. C. LANE, with one Palm, two Codiæums, one Begonia, one Anthurium Scherzerianum, and one Brassia verrucosa. This exhibitor was also 1st for a specimen plant.

FRUIT.

The 1st prize for Black Hamburgh Grapes was taken by Mr. W. Mancy (gr. to A. BENSON, Esq., Upper Gatton Park, Merstham), with capital examples; the 2nd prize falling to Mr. F. Keep (gr. to J. T. MITCHELL, Esq., Bath Hill, Redhill).

Mr. W. LINTOTT was 1st with Foster's Seedling, the bunches being of moderate size.

Strawberries (five dishes) were shown of Trafalgar and Royal Sovereign. Cucumbers were fine and large, likewise Melons, and a few dishes of Peaches and Nectarines were remarked; Broad Beans were shown largely, also Peas and collection of vegetables.

BIRMINGHAM BOTANICAL AND HORTICULTURAL.

JULY 4.—The second special flower show under the auspices of this society was held at the Edgbaston Botanical Gardens on the above date, and was a pronounced success. No fruit was shown, and only one group of Orchids was staged. Of plants entered for certificates, awards of merit were given to two border flowers and one hybrid Orchid. The attendance of visitors during the latter part of the afternoon was very gratifying.

The KING'S ACRE NURSERIES, LTD., Hereford, furnished a table, 20 feet by 6 feet, with Streptocarpus, Roses, and Carnations. The strain of Streptocarpus was meritorious by reason of the freedom with which the large and shapely flowers were produced, and although the Roses had passed their best, flowers of the following varieties were good: Killarney, Liberty, Mrs. Ed. Mawley, Bessie Brown, and Gardenia. (Silver Medal.)

Messrs. JAMES RANDALL & SONS, Hatfield Nursery, Shirley, Birmingham, staged thirty-six vases of Tree Carnations, in which the best of the new and many old varieties were represented by large bunches of flowers arranged with their own foliage in an effective manner. A silver-gilt medal—the highest award—was unanimously given for this splendid exhibit. Messrs. RANDALL also received a cultural commendation for half a dozen large well-grown plants of Nephrolepis exaltata Piersoni.

Messrs. BICK BROS., Warwick Road, Olton, showed an interesting collection of Alpine plants, Violas, and hardy cut flowers. (Bronze Medal.)

E. MARTINEAU, Esq., West Hill, Edgbaston (gr., Mr. O. Brasier), sent six vases of Malmaison Carnations. (Vote of thanks.)

Messrs. GUNN & SONS, Brookfield Nursery, Olton, made an extensive display of Roses, in which several little known species and many decorative varieties were shown. (Silver Medal.)

Messrs. RICHARD SMITH & Co., St. John's Nurseries, Worcester, and Mr. J. H. WHITE sent hardy flowers. (Bronze Medal.)

The only group of Orchids staged on this occasion came from the Highbury houses of the Rt. Hon. JOSEPH CHAMBERLAIN, M.P., Birmingham (gr., Mr. J. Mackay). A few of the best things were Phalænopsis amabilis Rimestadtiana, Cattleya Gaskelliana alba, Lælio-Cattleya Aphrodite, and Dendrobium filiforme, bearing an abundance of long slender racemes of tiny greenish-yellow flowers. (Vote of thanks.)

Mr. C. H. HERBERT, Acock's Green, exhibited hardy flowers (Silver Medal), and HUGH MITCHELL, Esq., Mercote Hall, had Pansies and Canterbury Bells.

The largest and most representative display of hardy border and bulbous flowers came from Messrs. DICKSONS, Chester, who had English and Spanish Irises, Lupinus "Somerset" (lovely canary-yellow flowers), Liliums, and a dozen stately Delphiniums, of which the varieties named Persimmon, light blue, and Mrs. Chamberlain, deep blue, were the best.

From Messrs. BLACKMORE & LANGDON, Twerton-on-Avon, Bath, came a collection of double and single-flowered Begonias, arranged in vases and Bamboo stands. (Silver Medal.)

J. A. KENRICK, Esq., Berrow Court, Edgbaston (gr. Mr. A. Cryer), sent a group of Schizanthus Wisetonensis and Delphiniums.

Messrs. JARMAN & Co., Chard, Somerset, showed New Centaureas and about 30 sprays of Zonal Pelargoniums. (Bronze Medal.)

AWARDS OF MERIT.

Lælio-Cattleya Aphrodite (Lælia purpurata × Cattleya Mendeli) from Messrs. CHARLESWORTH & Co., Heaton, Bradford. Sepals and petals unusually broad, pure in colour and of great substance; lip large, of rich velvety purple.

Centaurea The Bride from Messrs. JARMAN & Co., Chard, Somerset. The flowers of this new Sweet Sultan are nearly 3½ inches in diameter, white, semi-double, with deeply-cut petals.

Delphinium H. Smetham from Messrs. BLACKMORE & LANGDON, Twerton-on Avon, Bath. A strong-growing, much-branched spike of large semi-double, deep-blue flowers, tinted with purple.

SCOTTISH HORTICULTURAL.

JULY 3.—At the monthly meeting of this association, held at 5, St. Andrew Square, Edinburgh, Mr. D. W. Thomson, president, in the chair, a paper was read by Miss Barker, Corstorphine, on "Women Gardeners." Miss Barker, who has the distinction of being the first lady to address the association, said the suitability or unsuitability of gardening as an occupation for women had been so much discussed that it was difficult for most people to form a fair judgment on the subject. Excluding the heaviest work, there was no reason why a woman should not do well all that was required in a garden from the simplest work to the culture of the most exacting plant that could be raised.

CHESTER NATURAL SCIENCE AND CHESTER PAXTON.

THE members of these societies recently paid a visit to the summer residence of Colonel Evans-Lloyd (of Chester), at Moel-y-Garnedd. The gardens contain a fine collection of herbaceous plants and hardy flowering shrubs. Lupins, Centaurea montana, the beautiful Geranium armenum, Heucheras, Oriental Poppies in many colours, the grand Spiræa Aruncus, Globe Thistles, Inulas, Erigerons, Sea Holley, Delphiniums, &c., in great variety, were seen in the borders; Tropæolum polyphyllum covered a border with its glaucous leaves and curious flowers. Rodgersia podophylla, which is so difficult to establish, was well grown and flowering freely; but the great glory of all seemed to be a large shrub of the Ceanothus azurea, which was covered with a profusion of its small, light-blue-coloured flowers. On the way from Bala Station, the botanists of the party were fortunate in finding Meadow Rue (Thalictrum minus), Red Sandwort, Spurry (Spergularia rubra), Shoreweed (Littorella lacustris), Quillwort (Isoetes lacustris) and the Lesser Spearwort (Eleocharis acicularis). *George Paxton.*

MARKETS.

COVENT GARDEN, *July 11.*

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday, by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate, not only from day to day, but occasionally several times in one day.—ED.]

REMARKS.—English Tomatos are cheaper owing to the warm weather. Strawberries are also cheaper. Supplies from the Southampton district are nearly finished. English and foreign Gooseberries and Cherries are plentiful. Good Bananas are rather scarce. The vegetable and fruit trade generally is quiet. *Covent Garden Market, Wednesday, July 11, 1906.*

POTATOS.

Lincolns, 70s. to 80s.; Bedfords, 65s. to 70s.; Kents, 70s. to 90s.; Jerseys, 5s. 6d. to 6s.; Cherbourgs, 5s.; Dutch Rounds 3s. bags; St. Malo, 5s. to 5s. 6d. *John Bath, 32 and 34, Wellington Street, Covent Garden.*

COVENT GARDEN FLOWER MARKET.

The busy season is now over, and many stands remain empty. There is still a good supply of flowering plants. Show, Zonal, and Regal Pelargoniums are very good, but the best Ivy-leaved sorts are nearly finished for the season. Marguerites, both yellow and white varieties, are remarkably good, but trade in them has fallen off. Hydrangea Hortensia and H. paniculata grandiflora are still good. Liliums are not so plentiful; very good L. longiflorums are seen. Spiræa multiflora compacta is one of the best kinds, and

S. Silver Sheath is also nice. Fuchsias vary much in quality; some are excellent. Chrysanthemum segetum is seen from several growers. Coreopsis is now coming from Mr. Lewington; it is a pity this plant is not obtained earlier in the market, but I find all who try it fail, for the plants grow too tall and the blooms will not open. I believe this difficulty might be got over by saving seed from the earliest flowers, and growing the plants in light airy houses. Crassula coccinea and the hybrid varieties are still plentiful and good. Among roses some good Ramblers in small pots are seen, also H.P.'s, but they are not numerous. Foliage plants are plentiful and vary little in price, but it would not be safe to rely on the markets for best Crotons (Codiæums) and Cordylines (Dracænas).

CUT FLOWERS.

Roses continue over plentiful, especially those from the open ground which arrive early in the morning. Best blooms with long stems are not numerous. Carnations are plentiful and good in all varieties. Even at this late season the American varieties take the lead and have much depreciated the value of "Malmaisons," which usually make good prices during the London season. Hardy flowers are seen in great abundance, and now that hawkers are giving their attention to fruit, they do not clear well. I have never before seen Sweet Peas in such great abundance, and there must be many wasted, for at closing time large quantities are left over, and they are of no use for sale the next day. Liliums and other choice flowers are rather short, and prices vary much from day to day.

LA TRIBUNE HORTICOLE.—*Soyez la bienvenue* is the welcome to be extended to this the latest accession to the horticultural Press. It is published at 10 centimes (1d.) in Brussels. At present there is no other weekly publication of a similar character in Belgium. There are about 7,000,000 of people in that kingdom, 20 cities comprising among them representatives of remarkable energy, industry, ability and taste. Besides, horticulture may almost be reckoned as a speciality in Belgium, so that the success of the journal should be assured. In the first number we notice a description of a new Brasilian Orchid by M. DE WILDEMAN, Pleurothallis gracilis, var. Binoti. A supplementary illustration gives a representation of a new Cattleya, C. Mendeli var. Frau Lina Abeken, in which the segments are white, flushed with rose, the lip white with a magenta-coloured blotch at the base. Reports of the two Brussels societies, the Royale de Flore and the Royale Linnénne, will be given in the *Tribune* from time to time.

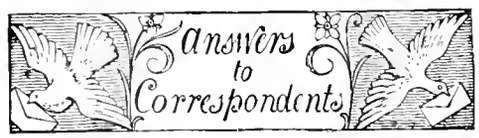
"NOS ARBRES."—Under this title Mr. CORREVON has just issued an illustrated treatise on the trees of Switzerland, to which we shall take an early opportunity of referring more at length.

THE FLORA OF TROPICAL AFRICA.—A new part of *The Flora of Tropical Africa* has lately been issued. It comprises the remainder of the Scrophulariaceæ by Messrs. HEMSLEY AND SKAN, the Orobanchaceæ and Lentibulariaceæ by Dr. STAPF, the Gesneraceæ by Mr. J. G. BAKER and C. B. Clarke, the Bignoniaceæ by Mr. SPRAGUE, the Pedaliaceæ (Pedalineæ) by Dr. STAPF. This part completes the fourth volume and is provided with a full index.

AMERICAN PÆONY SOCIETY.—The formation of a special society is no novelty in this country. What is noteworthy, however, is that such a society should be associated with a university. We can scarcely conceive our sedate Universities, such as Oxford or Cambridge, interesting themselves seriously in such, as they would judge, frivolous pursuits as Pæony growing. Our American cousins take wider views of the functions of a university, and so we find that the Pæony Society is to meet at Cornell University next year, that a large collection of Pæonies, nearly 2,000 varieties, is being grown and carefully studied in the college grounds, and that one of the advanced students is preparing a thesis on Pæonies for his doctor's degree in the university. The robes of a doctor of music in this country are gorgeous enough—what must be the apparel of a doctor of Pæonies? That the Pæony is not universally appreciated in America was illustrated by the fact that some time since we were dining at a public table decorated with bowls of Pæonies. The company consisted largely of Americans, to whom the flowers in question seemed to be quite unknown. We observe that among the visitors to the recent Pæony Exhibition at Boston were Mr. and Mrs. HUGH DICKSON, of Belfast.

ENQUIRIES AND REPLIES.

"TO CLEAN MARBLE, &c."—If *Hortus* would apply a solution of potash [of what strength?] [powdered] pumice-stone and whitening, and after 24 hours wash the vases, they should be clean. *N. S.*



*** *We are compelled to hold over a report of the Hanley Flora Fête, and other matters until our next issue.*

BEGONIAS AFFECTED WITH THRIPS: *J. W.* Dip the foliage in tobacco water and endeavour to promote a healthy growth in the plants by favourable cultivation.

CARNATION SEEDLING: *G. P.* The seedling is not so good as Mrs. Sinkin and many others already in commerce. The calyx is of the worst type, splitting badly. The Carnation and the Pink are such near relatives that crosses between them should excite little wonder. Mr. Douglas has even crossed the Sweet William (Dianthus barbatus), with a Carnation. However, you should preserve the seedlings, as they often improve in the second or third season.

CORRECTION.—In the note on Celmisias, on p. 2, line 17, the word "Rockery" was, by a printer's error, made to read "Valley."

CYMBIDIUM TRACEYANUM: *F. T.* There is no fungus present. The injury, known as "spot," is due to the deposition of moisture on the leaf during the night. This is caused by damping down the floor and stages late in the day, combined with lack of sufficient ventilation and decrease of atmospheric temperature.

FLIES: *J. G. E.* The flies are specimens of one of the "ruby-tailed flies" (Chrysis ignita). The mud nest was no doubt made by one of the solitary wasps belonging to the genus Odynerus which fills its nest with the larvæ of various insects as food for its grubs. The "ruby-tailed flies" do not make nests, but lay their eggs in the nests of the Odynerus, thus playing a part similar to the Cuckoo. This explains the presence of more than one kind of larva in the nest.

GRAPES: *Dulwich.* The Grapes are perfectly free from fungi, the markings being due to scald or contact with sunlight before the fruit has become dry on the surface.

GRAPES SPOTTED: *F. T. and M. O. Y.* The berries are affected with the "spot" disease. Burn any that are diseased and I spray the remaining ones with liver of sulphur—½ ounce to 1 gallon of water.

INSECTS: *J. C.* and *S.* The creatures in the glass phial are the common aphis or green fly at a particular stage in their development.

MUSCAT OF ALEXANDRIA GRAPES: *J. G. H.* The disease is that known as "Browning." See answer to *N. W.*, p. 116.

NAMES OF PLANTS: *W. W.* 1, Spiræa Filipendula; 2, Centaurea montana; 3, Erigeron speciosus; 4, Tradescantia virginica; 5, Scabiosa or Cephalaria; 6, Eryngium alpinum.—*S. Spieger.* 1, Priva tuberosa; 2, Zephyranthes sersilis; 3, Either a variety of Dianthus scaber or an undescribed species.—*R. S.* Lathyrus rotundifolius.—*W. W.* 1, Rubus, not recognised: no flowers present. The Japanese Wineberry is Rubus phænicolasius; 2, Primula, probably P. mollis; 3, Ruellia Portellæ; 4, Geranium pratense var.; 5, Lupinus nanus.—*J. McL.* 1, Veronica spicata; 2, Solanum Dulcamara; 3, Linum perenne; 4, Euphorbia Lathyris, the Caper Spurge; 5, Mimulus syn. Diplacus glutinosus; 6, Polygala myrtifolia grandiflora syn P. Dalmaisiana; 7, Pedicularis sylvatica.—*G. B.* 1, Poterium Sanguisorba; 2, Genista Scoparia.—*G. M.* 1, Not known; 2, Eryngium alpinum; 3, Campanula persicifolia; 4, Lupinus ornatus; 5, Iris pseudoacorus; 6, Chrysanthemum maximum; 7, Sidalcea malvæflora.—*J. W.* 1, Photinia serrulata; 2, Cassinia fulvida; 3, Ephedra nebrodensis; 4, Ruscus racemosus.—*Dunneford.* Trichopilia coccinea.—*D. S. G.* Tradescantia virginica.—*J. & Co.* Stachys lanata.—*S. J. H.* 1, Thuya dolabrata; 2, Thuya occidentalis; 3, Retinospora filifera of gardens; 4, Cupressus nootkænsis variegated; 5, Retinospora plumosa of gardens; 6, Cupressus Lawsoniana.—*J. G., Wimborne.* Hæmanthus puniceus, not a valuable species.—*J. B., Stockport.* The partly decayed flower is probably Cattleya Mossiæ. The damage was probably caused by excessive moisture and not sufficient ventilation.—*F. E., Hants.* 1, Selaginella lævigata, often called S. cæsia arborea; 2, Selaginella plumosa: 3, Selaginella flabellata; 4, Selaginella Wildenovi. The Lavatera was attacked by fungus, probably in the soil.—*P. M.* Apparently Echium vulgare, but specimen insufficient and shrivelled.—*G. R. D.* 1, Sisyrhynchium Bermudianum; 2, Artemisia abrotanum; 3, Epilobium angustifolium.—*T. W., South Wales.* Cupressus funebris, in its two stages of growth; the red colour is quite normal.—*A. C. H.* Anchusa italica.—*L. H., Wycombe.* 1, Campanula glomerata; 2, Agrimonia Eupatoria; 3, Galium palustre; 4, Melampyrum pratense; 5, Primula Forbesi: 6, Sedum album.—*W. H.* Glaucium luteum, orange-coloured variety.—*W. Y.* 1, Acalypha Macafeeana; 2, Bignonia cherere; 3, Alstrœmeria aurea; 4, Hemerocallis fulva; 5, Campanula pyramidalis; 6, Polemonium cœruleum; 7, Phalaris arundinacea variegata; 8, Centranthus ruber.—*H. H.* 1 and 2, varieties of Thunia Veitchiana; 3, Thunia Marshalliana; 4, Thunia Bensoniæ; 5, Brassia candata.—*H. E.* 1, Adiantum cuneatum grandiceps; 2, Adiantum concinnum; 3, Adiantum Capillus Veneris; 4, Adiantum Pacotii; 5, Adiantum decorum; 6, Acalypha hispida.—*Japonica.* Epidendrum oncidioides, Aspasia variegata.—*Ballyarthur.* 1, Mitraria coccinea; 2, Taxodium distichum; 3, Liriodendron tulipifera; 4, Sequoia sempervirens; 5, Azalea pontica; 6, Daphne Laureola; 7, Spiræa chamædrifolia.

NECTARINES INJURED: *J. W.* The damage is a physical one—there is no fungus present. The fruits appear to have been scalded by the sun when they were wet. See that they do not receive injury also from the wires.

PEAS DISEASED: *C. P.* Your Peas are badly attacked with a brown mould, Colletotrichum Lindemuthianum (Briosa and Cavara). Badly diseased plants should be removed and the remainder sprayed with Bordeaux mixture or potassium sulphide. A damp situation or sowing seeds too thickly would favour the disease. Do not save seeds from infected plants.

POTATO: *J. T. M.* The plant is badly attacked by the common Potato fungus Peronospora infestans. Spraying with a fungicide is very helpful at an earlier stage in preventing a serious attack, but you can do nothing for the present crop beyond removing the haulm as soon as it is dead and burning it. Lift the tubers as soon as they are ready, that those which are diseased may be separated from those which are not.

ROSE GRUB: *J. C. & Sons.* The edges of the Rose leaves are rolled by grubs of one of the "sawflies" (Blennocampa pusilla), a by no means uncommon insect, but one which we have never known to occur in such numbers as to be the cause of any real injury to the plants. The most effectual way of destroying the insect is by picking off the affected leaves and burning or burying them. Insecticides are of no use.

STRAWBERRIES INJURED: *E. N., C. S. G.* The injury has been caused by mice, which have eaten the seeds or pips. We have received similar injured fruits from the forcing houses earlier in the season.—*A. G. T.* The fruits appear to be rotting from dampness. There is no indication of disease.

TOMATO DISEASED: *R. F. and Another.* The fruits are affected with "spot" disease of Tomatos, Cladosporium lycopersicæ. Burn all diseased fruits, and spray the foliage and remaining fruits with Bordeaux mixture. See *Calendar of Garden Operations*, p. 45, obtainable from our Publishing Department, price 7½d. post free.

THE ROSE SEASON.

OWING chiefly to adverse atmospheric influences Roses, even in the most congenial situations, have demanded abnormal attention this year. The insidious Rose-caterpillar and the prolific green fly have had, in such a semi-tropical season, an extensive dispersion. The former was well compared, by the late Dean Hole, of Rochester, to a burglar who hides himself during the day in the shrubbery before he makes his nocturnal attack upon the silver in the dining-room.

But the devices of this monstrous regiment of insects can be easily discovered by the assiduous cultivator, who generally knows from long experience where to find his secret enemy, safely concealed—as it doubtless imagines—between two carefully glued leaves. My invariable practice is to detach and then isolate his leafy habitation, without depriving him of his life. After all, this insect, however destructive, is only obeying the instincts that Omnipotence has given him, and knows not what he does. In the case of the innumerable green fly no mercy is possible, if the foliage is to be kept in a healthy condition. Perfect flowers are impossible if the vitality of the embryonic buds is undermined.

Roses, nevertheless, are much finer this season than most cultivators could reasonably have anticipated. Perhaps an exception may be made in the case of the more tender Noisettes and Teas, many of which, such as L'Ideal, Madame Pierre Cochet, Maréchal Niel, Anna Olivier, William Allen Richardson, The Bride, and Madame de Watteville have unquestionably suffered much; and especially where, as in many gardens I could indicate, they have been utterly neglected. On the other hand, such varieties as the creamy-white Devoniensis, which is exceptionally beautiful at my study window, Madame Alfred Carrière, Bouquet d'Or, Papa Gontier, and Corallina, have never been more luxuriant in their floral beauty than they are this year. The lovely and sweetly-fragrant hybrid Noisette, to which I have just referred Madame Alfred Carrière—is at present flowering in my garden through a hawthorn hedge at a height of 13 feet; while Margaret Dickson, the Queen of Irish Roses, has attained an equal eminence on the southern wall of this manse.

In the great hybrid perpetual class, such lustrous crimsons as Duke of Edinburgh, Charles Lefebvre, Horace Vernet, A. K. Williams (whose first flower-buds, as usual, proved hard and abortive), Lady Helen Stewart, Duke of Teck, and those recent fine introductions from Dickmont and Newtownards, viz., F. B. Clark, Hugh Dickson, and Charles J. Grahame, are in flower. F. B. Clark, which Dean Hole would doubtless have characteristically described as "a bright, dark Rose," has already achieved a great reputation. Etoile de France, its Continental rival in renown, has not yet in my garden unfolded its full charms; but I can certify that it is in bud-form a supreme beauty, of rich maroon colour, and uniquely artistic. The grandest of all the hybrid perpetuals, whose satin-white flowers are seldom less than six inches in diameter, Frau Karl Druschki, sometimes more expressively entitled La Reine de Neige, is already conspicuous, *luna inter minores ignes*, by the purity and splendour of its blooms. Clio and Margaret Dickson, two varieties of quite inestimable value, whether as regards their remarkable growth or their floral achievement, are also grandly sustaining their great reputation. La France and Caroline Testout, Clara Watson, Viscountess Folkestone, and Madame Pernet Ducher are as florally effective as in former years. Among modern Roses, Florence Pemberton is especially fine.

That exquisite semi-double, so-called "Austrian Briar" Rose, Rosa Harrisoni, which has of late received well-deserved attention from the *Gardeners' Chronicle*, has been extremely beautiful and luxuriant this season. Grown, as it is invariably here, in artistic association with the brighter forms of the Penzance Briars, it is undoubtedly one of the loveliest of all Roses, of charming texture, and delicately refined. *David R. Williamson, Manse of Kirkmaiden, Wigtonshire, Scotland.*

OLD AND NEW EXHIBITION ROSES.

TO those who remember the exhibition of Roses many years ago in St. James's Hall, the comparison with the exhibition this year is interesting, though it may bring a shade of regret at the disappearance of many old favourite Roses. That is amply counterbalanced, however, by the wonderfully fine additions which later years have brought to the lists of excellent varieties: the gain in diversity of tints, in size and substance of the blooms, and in constitutional vigour has been so marked.

In one of the best lists of Roses for the present year 343 varieties are enumerated under the heads of hybrid perpetuals, hybrid Teas, and Teas and Noisettes. Of these 43 are new and hardly sufficiently proved, except in a few instances, for inclusion amongst established exhibition Roses. In the hybrid perpetual class 94 varieties are described, 48 of which have been raised since the National Society began its career. Of the remaining 40 that were the principal Roses in the section before 1877, with others that have been quite discarded, I only noted 10 as well represented in a few classes at the National Society's Show in the Royal Botanic Society's Garden this year. These were Alfred Colomb (1865), Charles Lefebvre (1861), Xavier Olibo (1864), three of Lacharme's productions, Duke of Edinburgh (Paul and Son, 1868), Duke of Wellington (Grainger, 1864), Dupuy Jamain (1868), Fisher Holmes (E. Verdier, 1865), Francois Michelon (Levet, 1871), Prince Arthur (B. R. Cant, 1861), and A. K. Williams (Schwartz, 1871). Of these the blooms shown were fully up to the highest quality seen in the old days, though they suffered somewhat in comparison with the giant blooms of the present time.

The hybrid Teas present a far more remarkable contrast, as when the first National Show was held the only two varieties that were recognised in this group were Captain Christy (Lacharme, 1873), and La France (Guillot, 1867), while of these I only remarked the latter in a few winning collections. Yet in the list referred to 100 varieties are described, and a considerable proportion of these were included in the exhibition.

Amongst Teas and Noisettes great changes have also taken place; out of 100 varieties catalogued 23 only were in cultivation before 1877, and of these I found but five at the exhibition a fortnight ago, namely, Countesse de Nadaillac (Guillot, 1871), Marie Van Houtte (Ducher, 1871), Niphetos (Bougere, 1844), Souvenir d'Elise Vardon (Marest, 1854), and Souvenir d'un ami (Defougere, 1840). The old Safrano and Homer, which are still favourite garden Roses, I did not observe in any of the prize stands.

Out of the total of 343 varieties in the three sections named it therefore appears that 73 date from years prior to the work of the National Society, and 270 have been introduced since, and a very large proportion of the blooms shown represented the later roses. Thus in a period of 30 years the great majority of Roses grown at the present time for exhibition purposes have been raised, including the whole of the British seedlings, from the late Mr. Bennett's time to the magnificent modern productions of Messrs. A. Dickson and Son, of the two Paul firms, and of those at Colchester. It is a surprising result, and there can be no doubt that the stimulus imparted to Rose growing and showing by the National Society has exercised a material bearing upon the advance. It has been my fortune to inspect many of the metropolitan and provincial exhibitions since the first national Rose exhibition held at St. James's Hall in 1858, and they have always been invested with the deepest interest, always varied, and also, let it be added, always well managed. *L. Castle.*

ORANGERIES.

In spite of the great development in plant culture under glass in recent years, how seldom are Orangeries mentioned? To my mind there is room for more of them. I do not mean copies of the semi-dark structures once so general in gardens, although Orangeries may, architecturally speaking, be of a somewhat heavier character than houses put up for most other special purposes. My ideal Orangery would be one directly accessible from the residence, of which it should form a part. In shape it should be either oblong or square, preferably the former. The sides and ends should be upright and not less than, say, 12 feet to the eaves of the roof. It would be best if the longest side faced the south, which, with ends, should be glazed to, say, within 2 feet of the stone, concrete, or brick walls that carry the whole building. The side facing north should not be glazed to more than one-third of its depth, but in order to keep the internal temperature from sudden fluctuations during the winter months, ventilation should be arranged for just under the eaves of the roof, and might take the form of narrow lights hung horizontally all around. If bottom ventilation be thought advisable, it may be arranged for in the basal walls, being careful to have the internal openings in direct contact with the water pipes to be fixed all around. Sufficient pipes and boiler power would be necessary to keep the internal temperature up to 55° in the winter without too hard firing. The roof should be a flattish span or spans, according to the space covered, avoiding, as far as possible, lanterns, domes, &c., which, while offering no cultural advantages, have a great tendency to lower the internal temperature in cold weather. It should, above all things, be as nearly drip-proof as is possible. Personally I would have the floor space all open and paved or tiled with some suitable material.

I need not go any further into constructional ideas, as doubtless any of our leading horticultural builders would gladly supply good plans if called upon to do so. Experience has proved to me that a house erected on something like the lines here shown is suitable for Orange tree culture and other plants that may be associated with them.

This brings me to the pith of my subject. My first heading was Orangeries and Palmetum; but, knowing that these notes were going to the *Gardeners' Chronicle*, and not to a lay paper, I struck it out and began again. From the outset I had (or thought I had) an instinctive idea that no one would put up merely an Orangery, as being too formal and stiff in these days of a more free and better taste in horticultural matters. Hence the idea of Palmetum. What more congenial companions could there be in the vegetable world than a well-arranged mixture of some of the better strong-growing Palms and well-grown specimen Orange trees in full fruit seen during the dull months from mid-October to mid-March? Imagine a house built on the lines given, and, say, 60 feet in length by 20 feet in width. On each side of the central path match pairs of specimen plants of Rhaphis flabelliformis, Kentia Belmoreana, and Oranges in variety in full fruit. I am careful to say "in variety," as I would not confine myself to edible oranges.

Close to where I am writing these notes there is a nice young tree of the Taranto Shaddock, full of fruit. The effect betwixt these fine pendent golden fruits and the green, healthy leaves of the tree, with a background of young Kentias, would be, to say the least, very inspiriting during the dull, foggy days of November. I would have all the occupants named grown in matched pairs of plant-tubs, now so much more handsome and come-at-able than those in days gone by. What more delightful retreat than such a house in the dull, dark days or long nights of winter? The plants named would, at that time, be perfectly happy in a temperature, both as to heat and moisture, congenial to its human occupants. Seats and rugs might be placed on the floor wherever required for pleasure and convenience. Nowadays, when the fruit and plant-houses are, in many cases, erected close to the dwelling-house, what a nice vestibule such a structure as I have suggested would be to them. There would be no fear of too much moisture being in direct contact with the mansion, as is the case with ordinary conservatories filled with a miscellaneous collection of flowering and foliage plants requiring water on most days even in winter.

I have described the cultural details of the Oranges and Palms suggested, as no doubt those who are in a position to erect such a building would have some specimens by them. In no case would I think of commencing with ordinary sized plants, as it would take some years before any good effect was enjoyed.

I may here mention that the internal atmosphere of houses erected with upright sides and ends is quite different from that in an ordinary span or lean-to greenhouse, even where the internal temperature is equal. There is an absence of that clinging stuffiness in the former nearly always present in the latter when the temperature exceeds 55°.

As bearing on my subject, I may mention in closing that we sent in last season dessert fruits of Embiguo or Navel Orange, which, I am told, were very good, one thing in their favour being freedom from "pips." It is a free-fruiting variety. *Henry J. Clayton, Grimston Garden, Tadcaster.*

FOREIGN CORRESPONDENCE.

AUS DEUTSCHLAND.

In Cologne the main street—Ringstrasse—as in some other continental cities, occupies the site of the old fortifications encircling the town. It is 2½ miles long and planted with Limes, an American type of Elm, Planes, and Horse-chestnut—none very good. Sycamore is also seen, and there is one avenue of the purple form. Such trees as Judas tree, yellow and red Horse-chestnut, are fine, and in one square two Catalpas—no doubt *C. speciosa*—are 40 feet high and 20 to 25 feet through. The chief public gardens are the Zoological and the Flora—neither very remarkable.

The country from Cologne to Berlin for the first 100 miles or so is bare of vegetation, but covered with furnaces and factories. The landscape round Essen as far as the eye can reach is black with the smoke of countless chimneys. Nearer Hanover the land is systematically planted with Scotch Pine and Birch, and the Pine may be seen in every stage from the planted seedling to the cut log in the railway truck. Much of the land is cultivated, chiefly with cereals, but Potatos are also a main crop. Asparagus and Turnip from time to time also appear. The villages are freely planted with trees, and standard fruit trees sometimes line the country roads in mid-Germany.

BERLIN AND ITS VICINITY.

Berlin is a fine city, covering 25 square miles, occupying the whole valley of the Spree. It is probably the first manufacturing town of continental Europe. The Thiergarten, 630 acres, is the private property of the Crown, and the Sieges-Allee is on a grandiose scale. The major portion is left as natural forest; the large areas between the roads—running in all directions—thick with magnificent trees. No park that I have seen in the old or new world in any way approaches this. Oak, 80 feet to 100 feet high, by the thousand, young and vigorous, will last another century. The trees are so closely planted that they have formed straight and even stems, each and all splendid "sticks." Limes and Poplars at their best, and Ash with stems 4 feet to 5 feet through—giants on the forest-carpet. Beech is rarely seen, and it is doubtful if Beech can be excelled outside several of certain private estates in England. The public are not allowed to walk on the grass, which is apparently always cut with the scythe. The Column of Victory is isolated and approached by four walks, each bordered by lines of thorns. Undergrowth is luxuriant beneath the shade of the taller trees, and consists largely of Snowberry, Elder, Alder, and Nut. Virgilia lutea is to be seen in vigour; Tulip trees, 70 feet to 80 feet; and on the stately mansions facing the park the Dutchman's Pipe (Aristolochia Sipho) 20 feet to 25 feet high.

The Zoological Gardens are extensive, and there are several good specimens, two male ostriches being quite exceptional. The main entrance is in the Chinese style, and the buildings in some instances are built to represent the form of structure prevalent in the country of which the animal it shelters is a native—the bison house in Red Indian style, Indian elephant shed in the style of a native temple. The birds are in no way comparable with those in London or the Jardin d'Acclimatation at Paris.

The Royal Botanical Garden, Dahlem, Steglitz, bei Berlin—director, Herr W. Perring—is quite new and as yet incomplete. It contains many of the plants removed from the old garden formerly in the Potsdamstrasse. The soil is not congenial, and at present there is throughout the garden no shade whatsoever. The nomenclature of the plants is not in every case that accepted at Kew, but is said to be based on the original authentic name. Large sums have already been spent on glass and iron erections, and more houses are in course of construction. For the completion of this garden many years will be required. The plants are in the main arranged according to their geographical source, and planted accordingly. It is *streng verboten* for any of them to die. The disregard of this autocratic order is, however, becoming rather obvious, as plants in several countries within a limited area grow naturally at greatly varying altitudes.

THE SPATH NURSERIES.

Herr Späth fifth head of the firm in direct line, owns the largest nurseries in Europe, 800 acres in extent, with a staff of 500 hands. The establishment is decentralized, and managed on the basis of individual responsibility and with that thoroughness so characteristic of the German nation.

The arboretum extends to the private residence, and is entered between two trees planted by Von Moltke and Bismarck respectively. The collection of deciduous trees and shrubs is very complete, but, with few exceptions, coniferous subjects are hardly at home. Caryas, Oaks, many species of Juglans, *J. Vilmorriana* particularly fine, Cercidiphyllum from Japan, Virgilia lutea, Sophora japonica, and Acer carpinifolium are all represented. The Keaki, that most valuable Japanese timber, is represented by a good specimen, as are also Idesia polycarpa and Phellodendron amurense, the bark forming serviceable cork.

The main stocks in the commercial part of the establishment consists of avenue trees and fruit trees. The avenues in the newer parts of Berlin are very fine, and rival those of the cities of the eastern United States, an avenue of Silver Lime, leading to Charlottenburg, numbering close upon 400 symmetrical and vigorous.

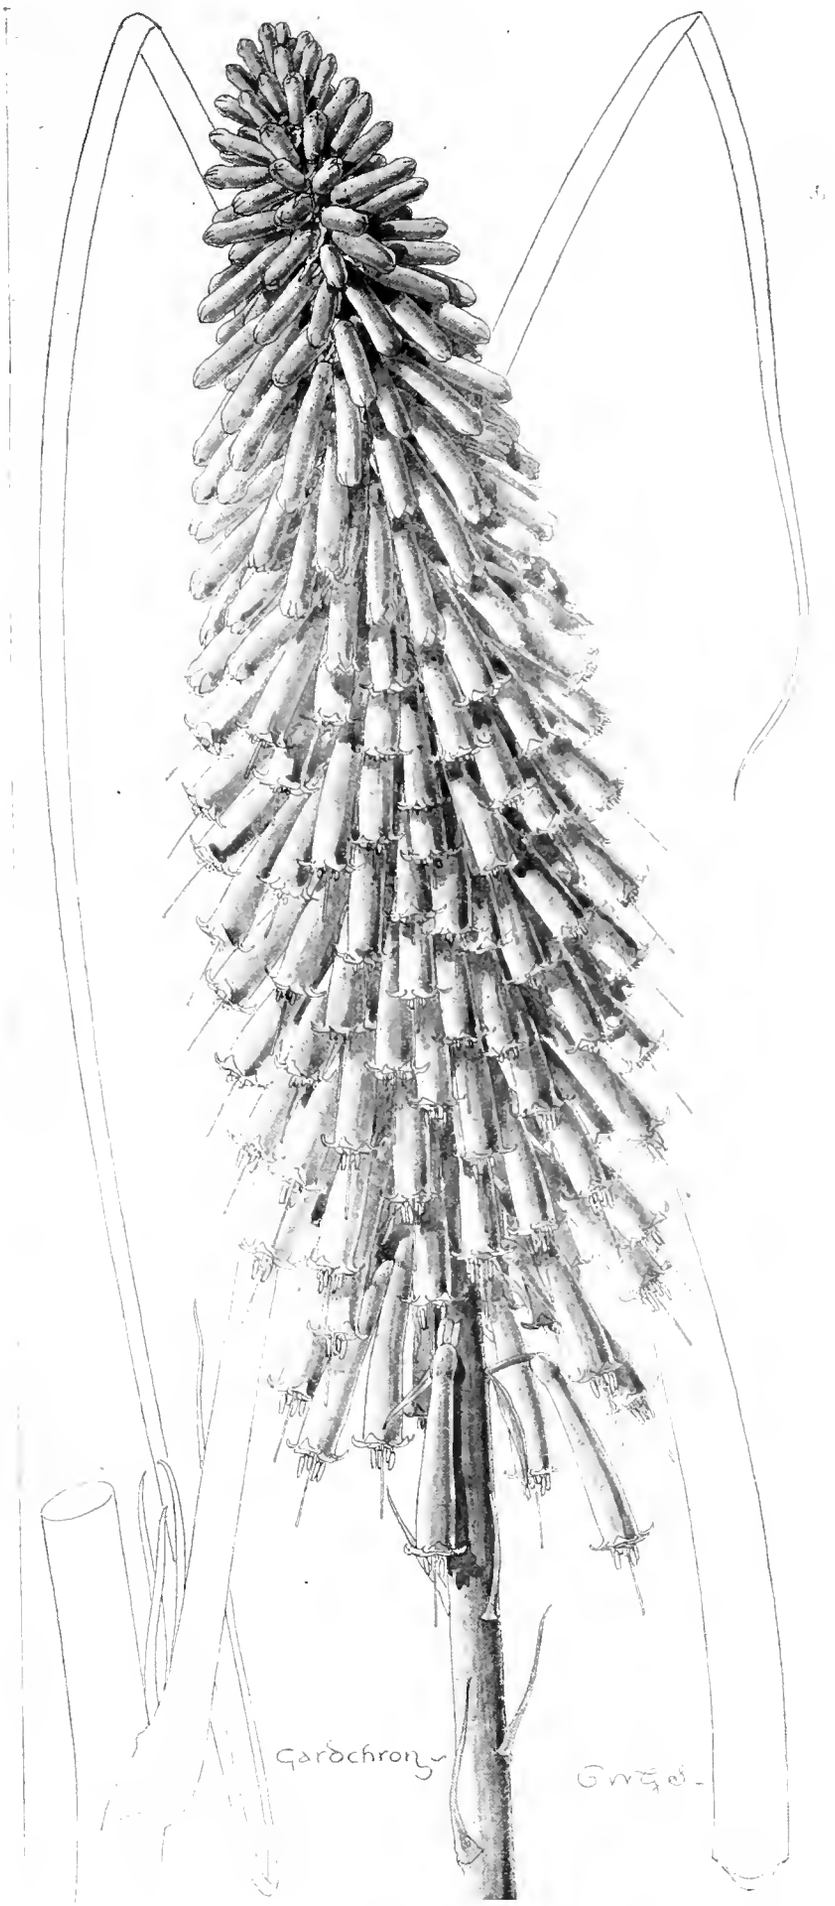

FIG. 19.—KNIPHOFIA (TRITOMA) × GOLDELSE; COLOUR OF FLOWERS CANARY-YELLOW.

trees. These make an impressive sight. The favourite avenue tree in the Eastern United States is Acer dasycarpum, but beyond comparison is avenue after avenue of Salisburia adiantifolia (Ginkgo), the tree selected for that noble artery which leads to the capital at Washington. Herr Späth says Koelreuteria paniculata is being tried in Vienna, and that he has, in order to show the Berliners the possibilities of the tree, planted an avenue of Pterocarya caucasica, which is in excellent condition. *J. H. W.*

KNIPHOFIA (TRITOMA) × GOLDELSE.

NOTEWORTHY on account of its graceful habit, equalled only by that of T. Nelsoni at its very best, this pretty hybrid between T. pauciflora and T. citrina should prove an acceptable garden plant indeed. The leaves are grassy and less than a yard long; the flowers, in slender racemes, are coloured canary-yellow throughout, and are borne in quantity from June till frosts occur in early winter. The plant originated in the nurseries of Messrs. Wallace & Co., of Colchester, and has proved its hardiness by withstanding the winters of 1904 and 1905 without suffering harm. Several other hybrid Tritomas, each with T. pauciflora as one parent, were raised at the same time, but none of the crosses yielded flowers so good as those of T. "Goldelse." Those interested in Tritomas, or Kniphofias, as they are more properly called, may be referred to a series of articles in *Gardeners' Chronicle*, pp. 81, 100, 117, of vol. xxxix (1906), in which most of the species and varieties possessing garden value are described at some length. *C. B. M.*

NEW OR NOTEWORTHY PLANTS.

SENECIO (EUSENECIO) FABERI.

Eighteen years ago I published (*Journ. Linn. Soc.*, Vol. xxiii., p. 452) a description of a Senecio under the above name, drawn up from a small dried specimen, collected by Faber on Mount Omi, Szechuen, Western China. Messrs. James Veitch & Sons recently sent to Kew a very fine fresh specimen of the same species, raised from seed collected by Mr. E. H. Wilson in the same locality. I am thereby enabled to complete my description, though there is not much to add except in the matter of dimensions. The genus Senecio is so numerous in species, and there are so many in cultivation, that it is difficult and somewhat hazardous to adjudge the claims a new species has to a place in a garden of moderate dimensions. S. Faberi is a robust, fleshy, and, perhaps, some would say, a coarse herb, that would form a conspicuous object in a wet part of the wild garden. The inflorescence reminds one of the Central American S. Warscewiczii, and the foliage is similar to that of the sow-thistle, but much larger. Under cultivation, it forms clumps 4 to 5 feet high, and is glabrous or glabrescent in all parts. Stems many angled, hollow. Leaves pinnatifid and coarsely toothed, with a large terminal lobe and usually two pairs of lateral lobes, the rest of the blade being reduced to a narrow wing running down the very thick stalk and expanding at the base into two large auricles, half clasping the stem. Radical leaves as much as 2 feet long; terminal lobe rotund-deltoid, 6 to 8 inches long and broad; lateral lobes 1 to 4 inches long; lower stem leaves nearly as large, but gradually smaller upwards; terminal lobe acutely triangular, 9 inches by 7 inches, coarsely toothed and obscurely lobed. The inflorescence is a dense, compound, flat-topped corymb, 6 to 8 inches across; flower heads very numerous, small, composed of three to five ray, and eight to twelve disc florets, all of a deep yellow. *W. Botting Hemsley.*

JASMINUM PRIMULINUM: ITS HISTORY AND CULTURE.

DURING the past spring one of the showiest and most attractive plants in flower in the Temperate House, Kew, was a batch of well-grown plants of this new Jasmine. Mr. Raffill, the foreman in charge, obligingly informed me that they had been growing in a sheltered recess outdoors for the past three years. In January last, finding they were a mass of flower-buds, they were carefully lifted and planted in one of the beds in the Himalayan wing of the Temperate House. The experiment proved a great success, the plants being one mass of bright yellow flowers, each flower being as large as a four-shilling piece. Some of the flowers were nearly single, others quite double, but in the great majority the corolla was duplicated after the manner of the so-called "hose-in-hose" primroses. These different forms are to be found on one and the same bush, and the same obtains even in the wild plants. In the Kew plants the persistent character of the foliage is very pronounced, and it was evident that the plant appreciated the treatment it received.

Jasminum primulinum is one of Messrs Jas. Veitch and Sons' recent introduction from China It is a native of the plateaux of Yunnan, at altitudes between 4,000-5,000 feet, the tropic of Cancer being practically its line of distribution Around the town of Mengtsze this Jasmine is fairly common in hedgerows, and as scrub by the wayside. On the low, rocky, treeless hills bordering Lake Shi-ping it is abundant. It was first discovered by W. Hancock, Esq., in the neighbourhood of Mengtsze, and was named by Mr. Hemsley, of Kew, and figured in *Hooker's Icon. Plant.*, tab. 2,384. Dr. Henry subsequently collected specimens in the same locality, and also at Szemao, in the extreme south-west of the province. In November, 1899, the writer, when returning from a visit to Dr. Henry at Szemao, succeeded in introducing living plants from Mengtsze to Hongkong, and these subsequently arrived safely in England.

Shrubs and trees which fail to produce seeds freely are expensive and difficult plants to introduce from a long distance. To this class this new Jasmine belongs, and the following details of its introduction may, perhaps, be of interest:—

A few weeks previous to my visit to Mengtsze the Customs Station had been attacked at night by an armed band of rioters, who set the place on fire. The Commissioner's house amongst others was reduced to ashes, and he and his wife narrowly escaped with their lives. They lost everything save the night clothes they had on, and several of their servants were burnt to death. The Commissioner's garden, which surrounded the house, suffered very considerably in the riot, but some fine bushes of Jasminum primulinum growing therein escaped. From these bushes the Commissioner's wife very kindly gave me four well-rooted layers. These layers were healthy, but rather soft, and it seemed advisable to obtain some older plants. The soil of the Yunnan plateaux is mainly clayey-sandstone of a brick-red colour, and, whilst adhering fast enough to one's clothes and boots, it will not stick to the roots of plants growing in it. However, four plants were eventually grubbed from the wayside in a more or less satisfactory manner.

The eight Jasmine plants were trimmed and "balled" up in Salvinia and Azolla, quantities of these being secured from a neighbouring pond and dried in the sun before using. Though not ideal packing materials, these two aquatics served the purpose very well. The eight plants were packed in two shallow ventilated boxes to form one mule's load. The boxes were taken by mule-train to Manhao, on the Red River, and from thence by boat to Laokai, on the China-Tongking frontier. At Laokai they were put on a tiny river steamer and, after four separate transhippings and much difficulty with the French Customs officials, arrived in Hongkong. The whole journey of some 900 miles occupied exactly three weeks, but the plants had not suffered in the least. By kind permission of Mr. Charles Ford, then superintendent of the Hongkong Botanical Gardens, the plants were taken to that establishment, potted up and allowed to get established, the opportunity being taken to propagate some young plants at the same time. I left them in the hands of the Botanical Gardens officials, who most obligingly offered to look after them and to forward a consignment to England when properly established. In the early summer of the following year (1900) a case of these plants was shipped home, but only one plant in the whole case showed any signs of life on arrival. Three or four cuttings were obtained from this plant ere it succumbed, but, by skilful manipulation, quite a good stock was raised from this small beginning. Later in the same year a second case was forwarded, and this arrived in a satisfactory condition.

Messrs. Jas. Veitch and Sons distributed the plant in the spring of 1903, and it is now to be found growing in many parts of this country and on the Continent. In the Riviera, I am informed, the plant thrives well. A friend recently returned from a visit from Cornwall, reports having seen some fine examples growing against sunny walls. But, so far, the plant has scarcely proved a success in this country generally, owing to its inability to withstand our winters with impunity, and, possibly, to the fact of its culture being not yet properly understood However, the magnificent pot plants exhibited by Leopold de Rothschild, Esq., of Gunnersbury, at a meeting of the R.H.S. in January last, is a hopeful sign. The sensation caused by the exhibition of these plants will, of a surety, stimulate other growers.

As a guide to the requirements of this new Jasmine, perhaps a few remarks anent the climate of its habitat may be of service. Yunnan, the most south-western province of China, lays partly within the tropics, and consists mainly of a series of plateaux having a mean elevation of 4,000-6,000 feet. The summer is one of torrential rains; the autumn is changeable; the winter and spring of bright sunshine and dry, fine weather. On the plateaux seldom more than a degree of frost is ever registered. Now a plant found inhabiting a region where the thermometer seldom falls below freezing point can scarcely be expected to prove quite hardy in this country. Nevertheless J. primulinum will withstand considerable frosts, as plants on a north wall at Coombe Wood, and those mentioned at the beginning of this note attest. Doubtless there are a few favoured localities in this country where it will succeed in the open, but the plant is best described as half-hardy. That the plant benefits from a considerable fall of temperature in winter is evident from the behaviour of those growing in the Hongkong Botanical Gardens, where, owing to a continual warm and moist climate, the plant grows and flowers sparsely practically the whole year round, but never makes any decided show. From my knowledge of the plant and its habitat, I should say that, if treated as pot-plants, plunged outside in a sunny position from late May until the end of September, well watered and fed, but not given over much root room, and in October placed in a frost-proof greenhouse, kept on the dry side in a well-ventilated position, where they can enjoy all the light possible, success will follow. Under such treatment the plants should be in full flower in February or early in March. Keeping them on the dry side in winter is important, but if this is over-done the plants will lose all their leaves before flowering.

J. primulinum was first figured from living material in the *Gardeners' Chronicle*, 1903, xxxiii., p. 197, shortly after it received a F.C.C. from the R.H.S. It was subsequently figured in *Flora and Sylva*, the *Bot. Mag.*, tab. 7,981, and various other horticultural and botanical journals.

Both in the *Bot. Mag.* and in *Flora and Sylva* Dr. Henry expressed the opinion that J. primulinum is nothing but a form of J. nudiflorum, which was long ago introduced into Yunnan, and, under a warm climate, has become evergreen and glorified, and now occurs as an escape from cultivation. The facts of his never having met with it in the forests, of its not producing seed, and of its tendency to produce "double" flowers, are adduced as evidence in in support of this theory. Whilst admitting that there is something to be said in its favour, I fear it is more plausible than accurate, and, for my own part, I do not agree with it. Without entering into the debatable question as to what constitutes a distinct species, I consider Jasminum primulinum a good species, and, without doubt, a native of the Yunnan plateaux. As to its not being found in the forests, J. primulinum is a sun-loving plant, and, like many other shrubs and herbs, would never occur in the depths of the forest. The non-production of seeds and the tendency to produce double flowers are more serious objections, but even these are not insuperable, since parallel cases are to be found in the same and other families. During the fifty odd years J. nudiflorum has been in cultivation in this country and on the Continent it has remained remarkably constant, exhibiting no variation whatsoever beyond mere variegation. This fact alone somewhat discounts the possibility of J. nudiflorum having given rise to such a widely different plant as J. primulinum. *E. H. Wilson.*

THE ALPINE GARDEN.

DIANTHUS ALPINUS.

THIS beautiful small Alpine Pink is easily cultivated in this country, and forms one of the most charming species in the rock garden. When in good condition and well established, it makes a lovely carpet of green foliage, and from this rise numerous bright pink flowers 1 inch in diameter on stems of about 3 inches in height. If planted about 6 inches apart in sandy soil and in a sunny position, and given frequent waterings during dry weather, it will need no other treatment

VERONICA ANOMALA

Is not so extensively grown as it deserves to be. It is usually recommended for sunny aspects, but it does not object to the shade, and would form a delightful plant for shady corners in the shrubbery, which is now occupied by some non-flowering shrub. I have seen it growing in quite shady positions to a height of 5 or 6 feet, and producing a mass of white flowers in July. Its elegant form and neat habit should commend it everywhere. *W. F. Glover, Langport, Somerset.*

LÆLIA MAJALIS ALBA.

IN Messrs. Sanders' group of Orchids at the recent Holland House Flower Show, was a specimen of the rare albino form of Lælia majalis. The remarkable purity of the segments, combined with elegance of form and a bold size, entitle it to rank among the most handsome of Orchids.

As far back as our issue for November 6, 1880, p 588, Reichenbach described the white form of Lælia majalis which was gathered by Mr. Petrasch, one of the numerous Roezlian nephews. The illustration at fig. 20 is from a sketch made by Mr. Worthington Smith at the Holland Park Show.

THE PROPAGATOR.

PROPAGATION IN THE MONTH OF JULY.

Ericas.—For the most part the propagation of these plants is carried out by means of cuttings inserted in March on mild bottom heat or in the present month, and in August in the cold greenhouse; and the species E. persoluta, E. tubiflora, and some others easily grown, may be rooted at other seasons. Cutting pots for Ericas should be large 60's or 48's, or pans of 2 to 3 inches in depth, and 4 to 5 inches in width, may be employed according to the number of cuttings to be inserted. At the bottom of the pots or pans, besides the hollow crock over the hole, there must be placed broken sandstone of Hazel-nut size to the depth of ½ inch, over this a layer of moss, and above it a mixture of clean silver sand 1 part, hard peat 2 parts, and over all a layer of clean, sharp sand, or pure sand may be used wherewith to fill the cutting pots, the cuttings being potted in this case directly they are rooted. Suitable cuttings are furnished by shoots taken quite close to the old wood, which have begun to take on a brown tint at the base; or, if side shoots are not available in sufficient numbers, the points of the side shoots may be taken. Cuttings should measure ½ to 1 inch in length. The softer kinds of Ericas produce roots from all portions of the cutting which are beneath the sand, and it is therefore unnecessary to leave any of the old wood on the base. It is only with such species as E. cerinthoides, E. Banksii, E. tricolor, &c., that a heel of old wood is essential, these making a callus before rooting. The leaves of all Erica cuttings must be cut off level with the surface of the sand layer, cutting them from below in an upward direction, and close to the rind. The bell glasses with which they are covered must be wiped every day in the morning or evening, and as the cuttings require to be kept rather moist the bell glasses should be sprinkled every day; the hairy species less frequently.

Some of the Andromedas, as A. hypnoides, A. tetrigona, and A. ericoides, may be similarly treated, and the North American species may be rooted from cuttings of the young shoots taken at this season.

Euphorbia pulcherrima.—The Poinsettia may be increased by cuttings of the young shoots when these are mature, without any drying off being necessary, using peat 2 parts, and sand 1 part, covering them with a bell glass. A bottom heat of 75° Fahr. should be employed.

Kennedyas may be rooted at this season, choosing as cuttings shoots that emerge from the stem of the plant. They require a moderate degree of moisture in the soil, no bottom heat and an atmospheric temperature of 50° to 55°

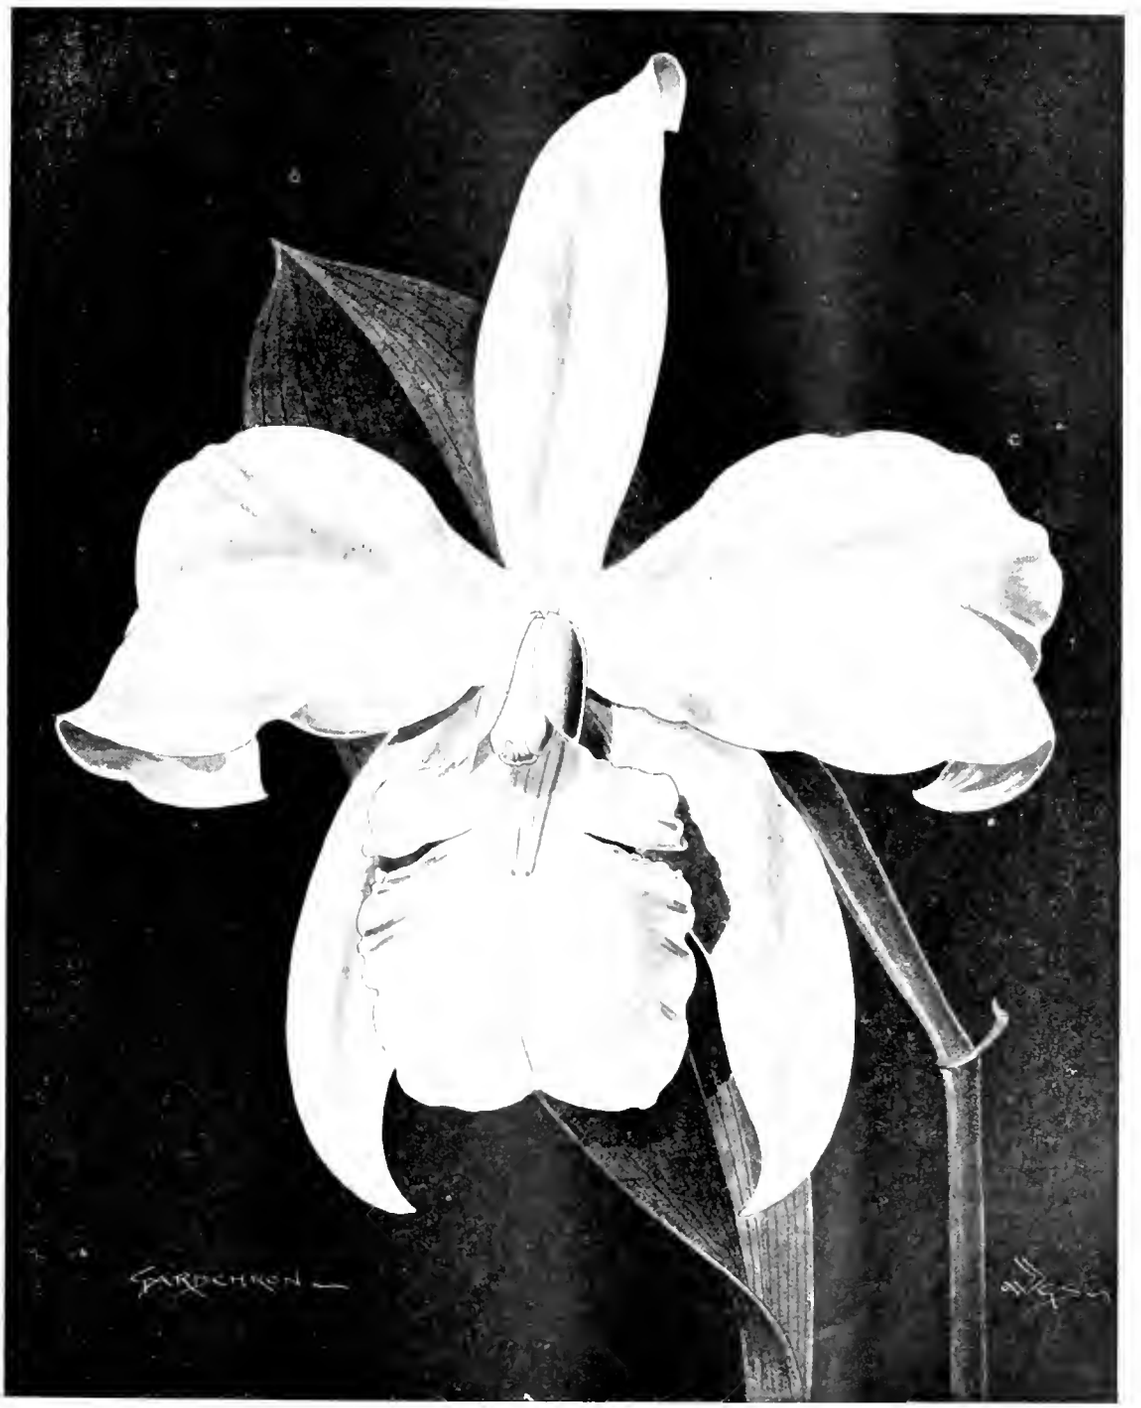

FIG. 20.—LÆLIA MAJALIS ALBA; FLOWERS PURE WHITE.

Pittosporums augustifolium, coriaceum, Tobira, undulatum, and others.—Choose perfectly mature shoots which have the end buds developed, and cut these square across at a joint. Put them into a mixture of peat and silver sand, the latter being about two-thirds of the whole. Apply water in moderation, and afford an atmospheric temperature of 45° to 50°, but no bottom heat.

Propagation by Means of Brood or Suckers.—Many species of trees, shrubs, and climbers can be increased by this means, and where suckers fail to develop, they can be made so to do by art. For example, the soil around an old specimen may be dug up with a fork, working some mild sort of manure into it in the operation, and this will be a means of inducing young growth to be developed from the roots, which at the proper time can be dug up and transplanted, and in the event of an insufficient supply of roots being secured with a sucker, it can be treated as a cutting, and put into a somewhat shady place till roots are formed. Even unhealthy specimens can be made to develop brood by chopping down the stem in the summer, and hacking the roots about midsummer with a spade driven deep into the soil, when numerous suckers will appear in the following spring. In that year, and still more the next year, the crop of suckers will be a plentiful one. Plants raised by this method make more suckers than the mother plants, and in the case of trees, these assume a shrubby character. I may here mention a few species that may be increased by suckers, viz., Ailanthus, Broussanetia, Castanea, Catalpa, Corylus, Deutzia, Eleagnus (especially argentea), Gymnocladus, Hippophae, Lycium, Mahonia, Menispermum, Myrica, Populus, Rhus, Ribes, Robinia, when on their own roots, Ruscus, Smilax, Sophora, Syringa, Tecoma, Weigela, Wistaria, and many of the Spiraeas.

Hyacinths.—Several bulbous species of plants as Lilies, Hyacinths, &c., are increased from broad, artificially produced. In the case of the Hyacinth, the bulbs which it is desired to propagate a few days after they are lifted out of the soil in July, are split with a knife across the crown in as many places as there are new bulbs wished for. A cut right across, ¼ inch deep, will afford from six to ten brood bulbs; and a cross cut 15 to 20 bulbs. The bulbs so manipulated should be laid out close together on plates, on a layer of sand, the crown uppermost, and in October these split bulbs must be planted. The following July they are lifted with all their broods of little bulbs, and placed on a layer of sand and spread out, the base of the bulbs upwards. In October the brood is separated and planted singly in nursery beds, and in the space of four years bulbs fit for forcing are obtained by this method. *F. M.*

PROPAGATION BY LAYERING.

To many gardeners the art of layering is only understood as applying to the propagation of Carnations, and possibly one or two other plants, but there are numbers of hardy trees and shrubs that can be better increased by this means than by any other. Layering affords a means whereby many trees and shrubs, and especially some of the rarer evergreen shrubs, can be propagated safely and readily without injuring the plant in any way, as the growth made by a plant after the whole or a part of it has been layered is nearly always stronger and healthier than would have been the case if cuttings, buds, or grafts had been taken from it. Plants raised from layering are on their own roots, and though it may be possible to raise them from cuttings, yet at the end of four or five years layers will be found to have made better and bigger plants than those raised from cuttings. This refers more particularly to evergreens, trees and shrubs, deciduous flowering shrubs such as Spiraeas, Deutzias, Ribes, etc., being raised so readily from cuttings that it is unnecessary to waste time in layering them. A few of the genera that are readily increased from layers are Andromeda, Aucuba, Berberis, Calluna, Calophaca, Calycanthus, Ceanothus, Chimonanthus, Clethra, Cornus, Dabeocia, Daphne, Erica, Exochorda, Garrya, Halesia, Hamamelis, Hedysarum, Hippophae, Ilex, Ledum, Leucothoe, Magnolia, Myrica, Phillyrea, Pteris, Rhododendron, Styrax, Syringa, Tilia, Vaccinium, Wistaria, and Zenobia. Plants of all the above genera will make roots readily when layered, especially the Ericaceous genera, which are especially easy to increase by this means. Camellias have failed to root when layered, though I have tried them in various ways and on different soils.

The method employed in layering hardy ligneous plants varies somewhat from that used for Carnations, etc. Tongueing is not necessary for anything except Exochorda, which is a difficult plant to layer, and which takes a considerable time to make roots. To prepare a plant for layering the shoots should be cleared of all leaves and small side-branches to within 6 inches or so of the top. The ground should be thoroughly dug around the plant, and all large stones, bits of stick, or roots be thrown out, so as to make the soil fine and easily worked. For layering, an old, flat-bladed trowel is necessary, with which a nick 4 inches to 6 inches deep should be made in the soil, and the shoot bent down and pressed into it, covering afterwards with soil, which should be made as firm as possible with the hands. The point of the shoot should be bent upwards as straight as possible, and made to stand out of the ground as far as the leaves have been left.

Layering can be done at almost any time of the year when the ground is workable, but it is not advisable to do it when growth is young and tender, as then the shoots are very liable to snap off when bent. It occasionally happens that a thick branch partially breaks near its base when it is bent, but if it is not entirely broken off it will be found to stand well enough to keep the layers alive. I have never observed the matter closely, but I have an opinion that layers form roots sooner when the branch is partly broken through. Layers are ready for taking off in from eighteen months to two years after they are put down, and should be cut off from the parent plant early in autumn, but not be taken up until the following spring, when they will be found to be well rooted and able to take care of themselves after being planted out. *J. C.*

THE HARDY FLOWER GARDEN.

Construction of Rock Gardens.

The old-time rockery, which was mainly reminiscent of a rubbish heap ornamented with broken crockery and a few stones stood, sentinel-like, on end, is fast becoming a relic of the past; but not all the modern representatives are very great improvements either from the point of view of the cultivator or the artist. One still has to endure structures of masonry which might be able to resist the guns of a besieging army, but scarcely to give foothold to any but the most vigorous of weedy growths, and withal are ugly and unnatural past adequate description. To ensure success from all points of view, it is absolutely essential that the constructor be experienced in the culture and requirements of the plants it is proposed to make a home for, and also that there be an innate love for, and an appropriate appreciation of, the way in which nature herself "houses" the vast number of Alpines in their native homes. Men to whom work of this kind is entrusted must have a natural aptitude or gift, with the knowledge which is only gained by experience.

The Planning and Planting of Borders.

The best material is almost worthless if badly managed, while second-rate matter may be resplendent when planned in an intelligent manner. When dealing with plants so varied and rich in colour, it becomes necessary to use great care in grouping, so that there is perfect harmony or pleasing contrast at all seasons. The juxtaposition of colours which do not "tone in" may spoil the effect of an entire scheme, and mar the enjoyment of the owner for the whole year. The mixed herbaceous border may be an endless source of pleasure and interest from January to December. There is practically no limit to the variety of plants which may be accommodated and the artistic effects which may be obtained. By a wise selection of plants, suitably arranged with due regard to colour, form, and time of flowering, a single border may furnish more pleasure and beauty than any equal space of ground treated in any other manner. Something has been heard of "monthly flower borders," and it is certain that more will be heard of them. This arrangement, whereby plants flowering at the same time are suitably grouped together, permits effects such as it is impossible to achieve with borders which must do duty over longer periods. Masses of rich colours in full beauty, blended with tender shades and graceful foliage, make a picture at once inspiring and satisfying. The "May border," remarkable for the soft shades which largely predominate, is charming in its fine grouping and broken surface. Bulbous plants are a feature here, and harmonise with Primroses and Forget-me-nots.

The "June border" partakes of a more stately character. Groups of Eremuri wave spikes of wand-like flowers over a wealth of dwarfer subjects. July and August each clothe broad undulating slopes with masses of colour.

The Making of Aquatic and Bog Gardens.

This is a comparatively new feature in landscape gardening, and one which unfortunately lends itself to abuse more readily perhaps than any other. Nothing can excuse or palliate a piece of water which is misplaced. No matter how the surroundings are "faked," it is an everlasting source of worry and irritation to well-balanced minds able to appreciate the eternal fitness of things. Just as nothing exists in nature without a reason, so there should be nothing in any part of the garden landscape which is not an essential feature of it. Obviously the best remedy in this case is prevention. Of the many ways in which beauty and charm are given to a landscape, it is certain that there is nothing so effective as water in various forms, whether as a placid river meandering through rich meadows edged with luxuriant reeds and Fleur-de-lis, or as a roaring mountain torrent, dashing 'tween steep rocky cliffs in innumerable cascades, reflecting light in showers of sparkling spray, and finally becoming subdued in a transparent pool bearing on its bosom the graceful leaves and bright flowers of Nymphaeas and other aquatic plants; or held in hollows between rugged hills, reflecting mountain pasture and leafy branches of noble trees. In any and every form there exists a charm bright and sparkling or contemplative and profound. A natural adjunct to a lake or stream is what may be termed a "bog" garden, for want of a better descriptive term, and this is a feature which is practically an assured success, if only the essen-

tial details be given a little consideration. Be the weather what it may, the rest of the garden scorched by hot suns, there is always this cool oasis where everything is fresh and green and revelling in sheer luxuriance. As a general rule, everything which likes abundant moisture will grow in some part of the bog garden, but if carelessly or ignorantly planted it may be nothing more than a mass of weeds. It is the knowledge which places each plant in its proper place that turns a potential morass into a luxuriant and smiling garden. Besides the showy perennials, which are the main features from a landscape standpoint, some of the prettiest and most interesting plants in existence find a congenial home amongst sub-aquatics. *E. Herton, Neston Cheshire.*

ARTHROPODIUM CIRRATUM.

THIS pretty New Zealand plant is now finely in bloom with me in the open garden. Seedlings were planted three years ago, and this is their first flowering. The leaves, about 1½ to 2 inches across, are gracefully recurved, and the large flower-panicles, holding from thirty to over a hundred blossoms, overtop the foliage by about a foot. The star-like flowers, which are pure white, have anthers partially orange-coloured, this tint contrasting well with the white of the blooms. It was introduced from New Zealand in 1821, but seems to be little grown. I find that snails and slugs are very partial to the foliage, and, unless carefully guarded against, ruin the appearance of the plants.

GLADIOLUS TRISTIS.

I NOTICE that on page 370 Mr. Arthur Grove writes of Gladiolus tristis, mentioning that he had sent a few blooms to the Editor. I should be interested to know what form of this Gladiolus he possesses. The one known under the name of G. t. concolor or sulphureus is by far the best, but, as far as I know, is not stocked by nurserymen. I have recommended many friends to procure this Gladiolus, but of the half-dozen who have taken my advice, all have been supplied with corms bearing flowers marked with a broad purple-black, central band on the three upper segments. The variety or type (?) concolor is destitute of these markings, the flowers being of a uniform pale sulphur colour, and is a much superior plant. An illustration of G. tristis concolor from my garden appeared on page 187, vol. xxxviii. of this paper. As Mr. Grove remarks, this Gladiolus increases rapidly from off-sets. It may be also rapidly propagated from seed which is freely produced. Last year I visited Mr. Archer-Hind's garden, where I found that this Gladiolus had seeded abundantly. Up to that time I had invariably cut the flower spikes as soon as the blooms had faded, but this year I left them with the result of obtaining some 200 seeds. One of the greatest merits of this Gladiolus is its early blooming, for in South Devon it flowers towards the end of April, far in advance of The Bride and others of the same so-called early section. Its delicious perfume after twilight is also much appreciated. *S. W. Fitzherbert, Devonshire.*

COLONIAL NOTE.

THE ERYTHROXYLONS OF GRENADA, W.I.

ON this island we have, so far, only found three species of the genus, namely, E. squamatum, E. oxycarpum, and E. ovatum.

The first-named species is found in certain mountain districts, where it develops into a small tree. The local name, and whether it flowers more than once a year, are facts at present unknown to me. The other two members I am better acquainted with, having had each under observation for several years past.

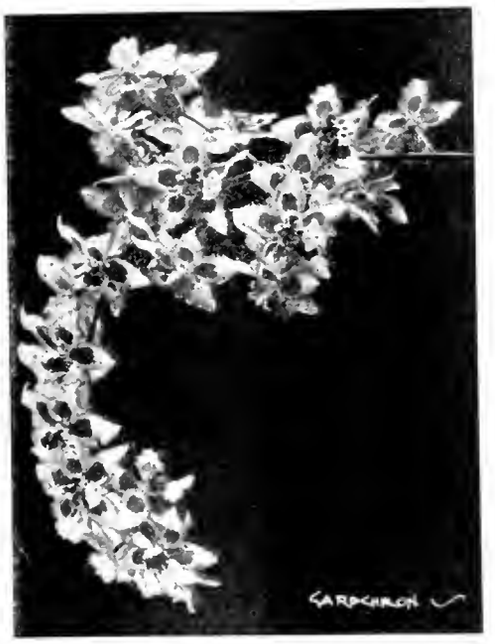

FIG. 21.—× ODONTIODA VUYLSTEKEI.

They grow in hedges, on banks, in pastures, and woods of low elevation, even down to the sea level. They are quite characteristic of the seaboard flora.

E. ovatum suddenly bursts into a mass of pure white flowers some weeks before the wet season sets in, say, in the month of March. At that time the leaves are unfolded, so that the plant is in full flower before they are developed. In about a month hence, bright red clusters of fruit take the place of the blossoms accompanied with fully formed leaves.

The bark is whitish. The upper side of the leaf is a pale green, including the mid-rib: underneath a milky shade. The general appearance of the whole shrub is lighter and whiter than that of E. oxycarpum.

The leaf of E. oxycarpum is stiffer, and the top side of the mid-rib is pale yellow. The bark is darker shaded. The period of flowering is later in the year. During the months of May and June flowers may be detached, but these blossom among the fully grown leaves and are yellow coloured. It grows into a big shrub, or small tree. Both species furnish tough, strong walking sticks, and each here is known as Red Flambeau. They may be seen growing intermixed, and by the novice are not easily distinguished. *W. E. Broadway, Grenada, June 23, 1906.*

× ODONTIODA VUYLSTEKEE.

OUR readers will remember the extraordinary Orchid shown under the above name at the Temple flower show two years ago, by M. Vuylsteke, of Ghent. The name is significant of the parentage, it being a bi-generic hybrid raised from Cochlioda Noezliana × Odontoglossum Pescatorei. Through the kindness of M. Vuylsteke we are enabled to present an illustration of the flowering spike as it appeared recently, from which it will be seen that the plant has lost nothing of vigour from the mixed marriage. The spike shown by M. Vuylsteke at the Temple show bore six flowers, each about 2½ inches across, one of which is represented in fig. 21. The flower was regarded by the Orchid Committee of the Royal Horticultural Society of such merit as to warrant the conferring a First Class Certificate without having the growing-plant before them, a rule which is rarely relaxed. The colour of the markings on the segments is peculiar, and is best described, perhaps, as "salmon cherry"; the toothed crest of the lip is yellow.

KEW NOTES.

ROSES AT KEW.

AT Kew may be seen all the various types of Roses growing in as natural a manner as possible. Such bold masses of one variety as are seen there can only be obtained in large parks and public parks.

In the Rose dell near the Pagoda and in beds and borders in other parts of the gardens the plants are allowed to grow pretty much at will.

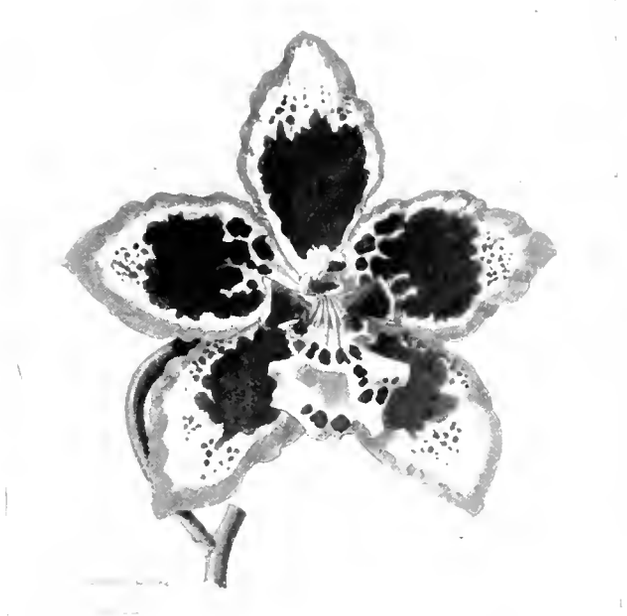

FIG. 22.—ODONTIODA VUYLSTEKEE, SINGLE FLOWER.

Little attention in the way of pruning is given beyond cutting out some of the old wood if the shoots become too numerous. The beds of the varieties Una, Electra, Morletti, Lord Penzance's Sweet Briars, and the varieties of Rosa rugosa are worthy of special mention.

Near the large Palm house many of the beds of hybrid Perpetuals, hybrid Teas, and Teas are at present gorgeous masses of colour. By growing only one variety in a bed the best effect is obtained. Without making these notes appear somewhat like a catalogue, it is difficult to know which varieties to mention. Leading place must be given to a bed of Caroline Testout, a mass of rosy-pink flowers, closely followed by the pearly-white Frau Karl Druschki; Mildred Grant is carrying huge blush-white flowers tinged with pink; very little foliage is visible looking on to the top of a bed of Captain Hayward, so closely is it packed with crimson-carmine flowers. Other varieties worthy of note are Killarney, Augustine Guinoisseau, Mrs. W. J. Grant, Madame Abel Chatenay, and Mrs. John Laing. Amongst the Teas Anna Olivier is one of the best. Princess de Sagan is worth growing for its colour alone (a rich velvety crimson), even were it not such a tree-flowering Rose. The deep rose-coloured Corallina is one of the newer varieties that has undoubtedly come to stay. Marie van Houtte, G. Nabonnand, and the old favourite Homère are also very good.

A beautiful effect is produced by pegging down the shoots of such vigorous-growing varieties as Cheo, a flesh-coloured H.P.; Frau Karl Druschki, and Gloire de Dijon. Words can hardly express the beauty of large beds grown in this way, presenting an almost flat surface of flowers. If grown and pruned in the ordinary way, the plants would have to be planted very thickly to obtain such a mass of flowers—even then I very much doubt if the effect would be so good; plenty of the shoots are carrying two to three dozen flowers on them.

Many of the climbing varieties on the Pergola, running parallel with the rockery, are covered with flowers. Practically all the sections suitable for the position are represented by one or more varieties. Dundee Rambler, Splendens, and Ruga represent the Ayrshire section. The Evergreen varieties Félicité et Perpétue and Flora are free growers, blooming in large clusters. The Multiflora hybrids are very popular pillar Roses. Aglaia, the Yellow Rambler, Crimson Rambler, Euphrosyne, the Pink Rambler, Helene, a mass of pale rose-coloured flowers with creamy white centres, and Tea Rambler, sweetly perfumed, coppery-pink flowers, are the best. The Boursault variety Amadis is covered with large, semi-double, purplish-crimson flowers.

The varieties named represent only a few of the best at present in flower. The Pergola was completed in its present form some five years ago. It is about 200 yards long, 13 feet wide, and 9 feet 6 inches high. The uprights are 17 feet apart, and are connected over the path by iron bars, and along the sides with chains. *D. D., July 14.*

The Week's Work.

FRUITS UNDER GLASS.

By T. W. Bunkshaw, Gardener to Lt.-Col. Sir Chas. Hamilton, Bart., Hatley Park, Bedfordshire.

Colouring of Grapes.—This is one of the most important points to consider in the cultivation of Grapes. Some varieties are much longer in producing a perfect "finish" than others. For instance, Madresfield Court, Muscat Hambro, Muscat of Alexandria, and Gros Colmar. These four varieties need considerable time and unremitting attention as to the affording of water and ventilation. The weather exercises very great influence in the colouring of the berries, and in some cases artificial means have to be employed in order to advance the process and produce that rich amber colour which is so much admired in the Muscat of Alexandria, Buckland Sweetwater, Golden Hambro, and Cannon Hall Muscat. Fresh air has also an important part in the process, and from the time the berries begin to change colour a fair circulation of air should be given, providing the external conditions are suitable. On dull, damp days it is necessary to have a little heat in the water pipes, and at the same time to admit a little air to the house. It will often be found that the best coloured bunches are those which are growing nearest to where the ventilators open. Nevertheless, cold draughts should always be prevented as much as possible, as they are exceedingly injurious. Where fruit is now ripening much mischief may result in hot weather if sufficient attention is not given to the matter of ventilation. The exact nature of the soil also exercises an important influence in regard to colour. For instance, on a heavy, strong loam, excellent bunches as regards size may be had, but Muscats will not develop in such conditions so good a colour as when grown on warmer soils. All artificial manures have good or bad effect on Grapes, and if used immoderately are sure to be injurious. It is always the safest plan to apply two small doses rather than one large one.

Muscat Grapes.—Where the fruit is changing colour, it may be necessary in some localities to apply a light shade over the glass, such as would be afforded by a garden net. It will serve to break the sun's rays, but more light may be allowed to pass through the bunches than would be good for black Grapes. Remove lateral growths at intervals of two or three days, so that no check may be given to the vines. Let water be afforded to the borders according to the stage of development the Grapes have attained.

THE FLOWER GARDEN.

By Hugh A. Pettigrew, Gardener to the Earl of Plymouth, St. Fagan's Castle, Glamorganshire.

The Carnation.—No garden is complete without this favourite flower for border decoration, and plants should also be grown in the reserve ground for supplying flowers for the furnishing of vases. Unfortunately, the Carnation does not succeed well in all soils, though in a deep loam inclined to be heavy and well manured with cow dung, they will continue for a few years in good condition and bloom freely. It is, however, even then preferable to renew the plants yearly, and in less favourable soils it becomes a necessity to do so. The best means of doing this is by "layering," and the present is an appropriate time for carrying out the work. To do this, the soil round the old plants should be removed to the depth of a few inches, and mixed with leaf mould and sand. The most suitable growths should be selected, and the leaves removed from the stem up to the top three or four joints. With a sharp knife make a cut through the shoot just below a joint which it is intended to make the base of the new plant, making a slanting cut upwards through the joint, bringing the knife out just above it. By means of a peg press the stem of the manipulated shoot into the new compost, taking care that the slit part of the joint is separated and pressed outwards from the stem. When all the shoots on one plant have been treated in this manner, cover in with the newly-prepared soil, and finally water carefully with a fine-rosed watering pot, to ensure the soil settling around the layers. After all the plants are layered, care must be taken that the soil is watered in dry weather, to encourage the rooting process. In about a month or six weeks the layers will have made roots, and in October the plants will require to be lifted, and either planted into their permanent quarters, or potted up and wintered in frames for planting out in spring.

Seedling Carnations are very easily raised, and if a good strain is obtained, the plants will flower much more profusely than the named varieties. For cutting purposes the flowers are invaluable. If treated liberally, the plants will bloom exceedingly well in the first season, but to obtain the best results they should be left undisturbed until the second season. May is undoubtedly the best season to sow the seeds in boxes, but if sown now, and potted up and placed in frames for the winter, they will make splendid plants for putting out next spring, and they will flower in the following autumn.

THE HARDY FRUIT GARDEN.

By W. A. Cook, Gardener to Sir Edmund G. Loder, Bart., Leonardslee, Sussex.

Wall Cherries.—Trees that have borne a crop of fruits this season must not be allowed to suffer from want of water. The growths should be well syringed with clear water to rid the foliage of any insect pests. A washing with an insecticide, such as Richards' XL All, may be necessary, and this should be used strong enough to rid the trees of red spider, should any have lodged on the leaves. If a second application is necessary, let it be done, for now is the time when the plant is ripening up its wood, and on this depends the next year's crop. Any worthless trees should be rooted up, and the ground prepared at the earliest opportunity for planting young trees. Varieties that succeed best in the particular district in which the garden is situated should be noted, also the time of the fruits ripening, in order to acquire for succession.

Gooseberries.—Early varieties must be closely netted, or blackbirds and thrushes will soon clear much of the fruit. Later fruiting varieties, especially those trained on walls, should be given ample supplies of water at their roots; they are also greatly benefited by an occasional sprinkling overhead.

The Loganberry, Strawberry, Raspberry, &c.—These should receive attention in the matters of watering, staking, and tying, for if these particulars are attended to, the labour will be amply repaid by extra fine fruits. Thin out any leaders that are not required. Mulch heavily after watering.

Pears.—These fruits should, at this time, have received their final thinning. Unfortunately, many good varieties dropped a large proportion of their fruits during the cold the first week in June, but there still remains a good crop on some of the better varieties. Any that are in clusters should be thinned out according to the estimated size of the variety, for small fruits of a large variety are, as a general rule, quite flavourless. Cordon-trained and small trees on the Quince stock will require great quantities of water and liquid stimulants at their roots, especially those on light and well-drained soils; and even trees planted in heavy ground will be much improved by an occasional watering from the sewage tank or farmyard byre. Should the mulching material be getting thin, apply an additional quantity, for this is one of the best and cheapest methods of guarding against the effects of dry weather. Probably the greater part of the heavy rainfall on June 27 was carried away by the drains, and came too hastily to benefit the trees to any great extent.

Strawberries.—These should now be layered in quantity for the making of new plantations. Early-layered plants, intended for forcing, should be severed from the old plants, and be afterwards placed in frames for a day or two, and kept shaded. When they have recovered from their disturbance they should be finally potted in their fruiting pots. Layers are the best when secured from one-year old plants, but as all growers have neither the time nor the space to grow these, they have to depend upon those from two-year-old plants, and these do very well. In order to keep up a good supply of fine fruit, the beds should not remain longer than three years. A new bed should be made every year, and a corresponding one destroyed. Plants of Royal Sovereign that have been forced and afterwards planted out of their pots may reasonably be expected to produce fruits in the autumn. Several other varieties of Strawberries will also bear a second crop in this way in the autumn.

Preparing new Strawberry beds.—The ground should be well dressed with manure and dug over. An ideal quarter is an old Onion bed, and although it is late in the season when the Onions are removed, I have planted much later and with success. An Onion bed is already enriched with manure and well trenched, and young Strawberry plants revel in such conditions.

THE KITCHEN GARDEN.

By J. GIBSON, Gardener to His Grace the Duke of PORTLAND, Welbeck Abbey, Notts.

Asparagus.—The growths are now becoming top heavy, and to avoid any chances of their getting broken or twisted they should be secured by stakes or tied to lengths of string stretched along the rows. Nothing is more preventive of good results than damage to the top growths, as the strength of the next season's crowns will greatly depend upon the foliage. If time can be spared, supplies of liquid manure should be given the plants, especially during dry weather. Keep the beds free from weeds and from seedling Asparagus plants.

Potatos.—The lifting of early crops will now be in progress, and this will afford a suitable opportunity for selecting seed tubers for next season's crop. It is best to select these when the crop is being lifted, as they can then be selected of a proper size. With us the best early varieties are Ringleader, Sharpe's Victor, May Queen, and the newer Sutton's Gladiator, which is an improvement on May Queen. These are all "first earlies," and are first-rate kinds, either growing in the open border, frames or pots. Main crop varieties generally promise well this season. Keep the rows free from weeds, for these do damage by choking the leaves of the Potatos.

Peas required for exhibition, or for special purposes, should have the points of the growths pinched out about five weeks before they are required, and, if possible, immediately above the second truss of flowers. It makes much difference to the length of the pods when the plants are thus treated, and to the size of the individual Peas themselves. Tying the growths to the stakes is also essential in order to prevent the pods from becoming damaged by the wind, which sways them about and rubs the bloom off. Seeds of any special variety should only be saved from the very best pods with a view to getting an improved stock; for selection, if persisted in, undoubtedly makes a great improvement in the Pea crop.

Marrows.—These are now growing strongly, and should have their growths regulated and pegged down. The points of long growths should also be pinched to induce the formation of side shoots. Should green fly attack the plants, syringe them with a solution of quassia and soft soap, and give plenty of water, both overhead and at the roots. Cut the Marrows as soon as they are large enough to be useful rather than exhaust the plants by leaving them until the fruits become ripe and of little value. Small fruits are preferable to large ones.

Endive.—During the autumn, when Lettuce is not plentiful, this vegetable is of great value; periodical sowings should, therefore, now be commenced. The broad-leaved Batavian is certainly the best variety, but if another kind is also required, the fern-leaved variety should be sown. To prevent premature seeding, plant the seedlings in rich well-cultivated soil, and give copious supplies of water during dry weather. Many salads are often spoiled by neglect of these details.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower to Sir TREVOR LAWRENCE, Bart., Burford, Surrey.

Bulbophyllums, Cirrhopetalums, and Megacliniums.—Very seldom does what is generally termed a "botanical" Orchid attract so much attention as the remarkable Bulbophyllum virescens did at the recent show at Holland House. It is surprising that the species of Bulbophyllum do not receive more attention from growers. Bulbophyllums and Cirrhopetalums, which are closely allied, constitute a numerous group of beautiful and singular flowering plants, many of which deserve a place in every collection of Orchids. I have remarked in a former Calendar that no description can give an adequate idea of the quaint distinctiveness of many of these, or of their varied charms, which in a representative collection are present in more or less degree throughout the year. Such species as the remarkable B. Ericssoni, B. grandiflorum, B. longisepalum, B. tremulum (the hairy lip of which closely resembles a hand brush), the delicate mechanism of the lip of B. barbigerum, and the oscillating labellums of B. Dearei, B. Reinwardtii, B. Lobbii, and its variety siamense, &c., always attract attention; while the striking umbrella-like spread of the sepals of Cirrhopetalum Mastersianum, C. ornatissimum, C. Cumingii, C. O'Brienianum, C. Roxburghii, C. Amesianum, &c.; also the distinct C. Collettii, C. picturatum, C. Thouarsii, the strange-looking C. Medusæ with long sepals, which has the appearance of dishevelled hair (see illustration at Fig. 6 in *Gardeners' Chronicle* for January 9, 1897), and many others, are exceedingly pretty and interesting. The compact growing C. nutans, smothered with umbels of small white flowers, makes a charming object. A small collection of these botanical Orchids would occupy but little space, especially as the majority thrive well in shallow pans that may be suspended close to the roof. Those with long creeping rhizomes should be planted in shallow teak-wood baskets of sufficient size. These receptacles should be filled to about three-fourths of their depth with clean crocks or firm pieces of well-dried fern rhizomes, putting a thin layer of rough sphagnum-moss over these, upon which the plants should be placed, carefully spreading out the roots over the surface of the moss, and filling up to the rhizome of the plant with peat and moss in equal parts, mixing a moderate quantity of small crocks with the compost. The plants should be re-potted when new growth commences, which usually occurs soon after flowering. All of them will thrive well in a warm, shady part of the Cattleya house, but a similar position in the East Indian house or the ordinary plant stove will also suit them. There are, however, some varieties which come from high altitudes, and should any of them show signs of ill-health remove them at once to a cooler and more freely ventilated atmosphere. These plants enjoy an abundant supply of water during the growing season, and for this reason should be examined two or three times each week. While at rest, even in summer, they need but little water, yet they should be sprayed over occasionally to prevent shrivelling of the pseudo-bulbs, or the plants will be permanently injured. The plants are not often attacked by insect pests, but an occasional sponging of the leaves becomes necessary in order to maintain them of a healthy clean colour. Another curious and interesting section of botanical Orchids are the Megaclinium, which are closely allied to Bulbophyllum and Cirrhopetalum, but are distinguished chiefly by the flowers being borne on each side of a flattened rhachis. As in Bulbophyllum, the labellums are often so constructed that with very slight motion they are thrown backward and forward as though they were set upon a delicate hinge. Megacliniums require similar culture to that given to Bulbophyllums, &c. A few of the best varieties are M. triste, M. Clarkei, M. bufo, M. falcatum, M. purpuratum, &c. The section once known as "Sarcopodium" are now all included under Bulbophyllum.

PLANTS UNDER GLASS.

By B. CROMWELL, Gardener to T. SUTTON TIMMIS, Esq., Cleveley, Allerton, Liverpool.

The Colouring of Codiæums (Crotons).—These claim a leading position among plants cultivated for the beauty of their foliage, and must be given the careful treatment all first-rate plants need, otherwise Crotons in culture will prove a failure. The essential details to be observed in the colouring of these plants are light, heat, moisture, cleanliness, and good feeding. Light, with as much sunshine as the plants will bear without suffering injury, is essential, for, failing this, it is impossible to obtain rich colouring in the foliage. The plants should be kept close to the glass, and if a little air has been admitted to the structure from an early period in the season, it may now be increased with advantage, and direct sunshine allowed without fear of the leaves scalding. The house should be closed early in the afternoon, allowing the atmospheric temperature to rise to 95 or 100°; these high temperatures apparently develop the rapid colouration in the leaves. A moist atmosphere must be maintained, and during the season of growth it is hardly possible to have it too moist. A good practice is to damp the structures and plants about 8 to 9 p.m. On no account should the plants become dry at the roots, as loss of foliage would be certain to follow. Above all, see that the foliage is clean, for if mealy bug is present the conditions of the atmosphere will be suited to its rapid increase; therefore spraying with insecticide should be followed up. Feeding is important to develop the foliage to its greatest limits, and Codiæums need a large supply; but no animal manure is employed at Cleveley in the growing of Crotons. Standen's manure is the principal fertiliser used. There is yet time to improve the colour in any plants which may be indifferent, if the above directions are followed out.

Pot Roses.—Examine plants which are intended for forcing during the coming winter. If the soil and drainage are in good condition, repotting will not be needed, but a top dressing may now be applied, and this should consist of good fibrous loam and a sprinkling of bone meal and coarse sand. Should the loam be very heavy, add one-sixth part of good leafmould. Encourage the plants to make healthy growth, affording them frequent applications of clear manure water. Remove any flower buds which may appear at this time, and endeavour to build up a good constitution in the plants as the season for maturing the wood advances.

Gardenias.—Keep those plants in cooler conditions which are intended for flowering early or autumn and in winter. The plants may be exposed to full sunshine and ventilation, so that the growth may be thoroughly matured; this must be done gradually, otherwise the plants may suffer a check. For the production of early flowers thoroughly ripened wood is necessary, and then with an increase of temperature the plants will soon form and swell their flower buds. Clay's fertiliser is an excellent manure for these plants. Insert cuttings of young shoots for raising a stock of plants for next season.

THE APIARY.

By CELERIS.

Foul Brood.—This is a disease commencing with a very minute germ called a spore, which comes in contact with a larva, or may be consumed by it. The spore has wonderful vitality, and once it finds suitable conditions, it germinates and develops into a bacillus. Having exhausted its feeding ground, spores are produced to again continue the disease, given suitable conditions. It should be noted that the disease attacks brood, and, without brood, cannot make headway. When a larva has been attacked, it dies, and dries into a brown scale, which lies on the lower side of the cell. Should honey be stored in the cell, or an egg be laid in it, the result is equally disastrous. The honey may be fed to other larvæ, and thus spread the disease, or the larva will hatch to die.

What it looks like.—Generally speaking, the beginner would notice a difference in the odour arising from the hive when the quilts were raised. The dead larvæ turn coffee-coloured, become a stringy mass, and, when in an advanced stage, smell like bad glue. The cappings over the diseased brood cells are broken and sunken. If a piece of stick be thrust into an infected cell, the sticky matter will adhere to it and stretch out an inch or more, then break and return like elastic to the cell.

Remedy.—Should the disease be in an advanced stage, it will be well to destroy the quilts, hives, and bees, and make a fresh start. In the early stages the bees should be shaken from the frame into an empty skep, there to remain covered in confinement for 24 hours. Thoroughly cleanse the hive by washing with carbolic, boil all the fittings, or, as these latter are cheap, it would be better to destroy them by fire. Fit up the frames with starters, cage the queen, in three or four days remove the starters, melt into wax, and fit up with full sheets of foundation, keeping the queen caged for five or six days more. If the old combs are returned, they should be melted into wax by boiling, otherwise the wax will become a source of infection. The hive would stand on the old site. When the disease is discovered, act promptly but with discretion. Close all the entrances of the hives, so that one bee only may pass at a time, in order to prevent robbing; for this would only help to spread the disease. Generally speaking, it is useless to deal with a weak colony; they are not worth the trouble, nor is it likely to be successful, nor can the scourge be coped with during the early spring. Now is the time to eradicate it when the honey flow is in full swing.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, *as well as specimens and plants for naming, should be addressed to the* **EDITOR, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Special Notice to Correspondents.—*The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.*

Illustrations.—*The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c., but he cannot be responsible for loss or injury.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.*

Local News.—*Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

APPOINTMENTS FOR THE ENSUING WEEK.

SATURDAY,	July 21	German Gardener Soc. meets.
TUESDAY,	July 24	Nat. Carnation & Picotee Soc. Sh. in Roy. Hort. Hall, Westminster.
WEDNESDAY,	July 25	Cardiff & County Hort. Soc. Exh. (2 days). Newcastle-upon-Tyne Fl. Sh. (3 days). Dingwall Fl. Sh. Ewell Cottage Gardeners' Sh.
THURSDAY,	July 26	Ulster Hort. Sh. (2 days). Bridgwater Fl. Sh. Scarborough Fl. Sh. (2 days).
FRIDAY,	July 27	Roy. Bot. Soc. meets.
SATURDAY,	July 28	Dutch Gard. Soc. meets.

AVERAGE TEMPERATURE for the ensuing week, deduced from observations of Forty-three Years at Chiswick—63.4

ACTUAL TEMPERATURES:—

LONDON.—*Wednesday, July 18* (6 P.M.): Max. 80°, Min. 56°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—*Thursday, July 19* (10 A.M.): Bar., 30·0, Temp., 61°, *Weather*—Showery.

PROVINCES. *Wednesday, July 18* (6 P.M.): Max. 80° London, Min. 55° Liverpool.

SALES.

FRIDAY—

An Importation of Cattleya Trianæ, also other Imported and Established Orchids; Orchids in flower and bud, at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 12.45.

SATURDAY—

A well-arranged Horticultural Property, Mount Pleasant Nursery, Vicarage Lane, Hailsham, Sussex, at Caldredge Hotel, Eastbourne, by Protheroe & Morris, at 4.

The "Botanical Magazine."

Very few, if any, publications can boast of so long and unbroken continuity as the *Botanical Magazine*. It first made its appearance in 1787, and the July number for the present year, containing the plate No. 8080, has just been issued. Throughout its whole career the main object of successive editors has been to produce accurate illustrations and authentic descriptions. Without in any way pandering to the caprices and fashions of the day, it nevertheless reflects impartially the state of garden-botany during the hundred and nineteen years of its existence. In the early volumes hardy European and North American plants furnished the material for the majority of the representations. Afterwards the Cape of Good Hope supplied Heaths, Pelargoniums, Mesembryanthemums, and various succulent and bulbous plants, some of which are no longer to be found in our collections. The first Fuchsia (F. Magellanica) was figured in the third volume, t.ab. 97. The first Orchid (Calopogon pulchellus) was shown on plate 116. The Chrysanthemum, though previously cultivated by Philip Miller, was not generally known or appreciated till it was figured in the magazine (tab. 327), (1795). In 1801, on the death of William Curtis, Dr. John Sims, an eminent physician of the day, undertook the editorship, and continued to control its destinies till 1826, with much help from Bellenden-Ker (formerly Gawler), R. A. Salisbury, and Dean Herbert, Sydenham Edwards being the artist. The magazine went through various vicissitudes till, on plate 2,689, we first meet with the name of William Jackson Hooker. From 1827 onwards Dr. Hooker, afterwards Sir William, conducted the magazine with a degree of success, whether as regards artistic fidelity or technical accuracy, which has never been surpassed. Hooker's labours were so multifarious that even his powers of work were not adequate to the task of continuing to delineate the plants he described, and in consequence, as early as 1834, he availed himself of the services of Walter Fitch, who continued to enrich the magazine with his drawings down to the year 1877. Subsequent illustrations have been supplied by Lady Thiselton-Dyer and Mrs. Barnard. The present artist is Miss Smith, who was educated for the purpose by Sir Joseph Hooker, and whose faithful representations are much appreciated. In 1865 Sir William Hooker died, and was succeeded, both in the Directorate of Kew and the editorship of the *Botanical Magazine*, by his son, who inherited his father's powers of work, zeal, and talents as a botanist. He joined to them the experience of a traveller and explorer in many lands. It is no wonder, then, that the reputation of the magazine was not only maintained, but enhanced, under his direction. Sir Joseph continued to act as editor till 1904, since which time the periodical has been conducted by Sir William Thiselton-Dyer, who has lately retired from the Directorship of Kew. During three successive directorates, therefore, the *Botanical Magazine* has been in a sense, though not officially, connected with Kew. Since 1845 the magazine has been published, with exemplary punctuality, by the well-known firm of Lovell, Reeve and Co.

We have alluded thus cursorily to this honoured publication for the purpose of drawing the attention of our readers to the recent publication of "a new and complete index to the *Botanical Magazine* from its commencement down to the end of the third series in 1904." This index has been prepared by Mr. W. Botting Hemsley, F.R.S., the curator of the Herbarium. Working botanists and horticulturists cannot be too grateful to Mr. Hemsley for its preparation, though they will assuredly regret the omission in every case of the name of the author responsible for the name of the plants figured. As the omission can be readily supplied by reference to the work itself, this is, after all, a matter of minor consequence. But Mr. Hemsley has done more: he has prefixed some historical details relating to the general history of systematic botany in its relation to horticulture, including references to other publications, which, for the gardener-botanist, are of entrancing interest. The basis of this portion of the volume consisted in a series of articles contributed to the *Gardeners' Chronicle* in 1887 by Mr. Hemsley, and now reprinted with many additions and some modifications. With this index, reaching back to the latter part of the eighteenth century, and extending to our own times, and with the superb "Hortus Veitchii" to which we have recently alluded, the student has at his disposal invaluable material for reference, and the historian of garden-botany a boundless store of information conveniently arranged for his purposes.

HORTICULTURAL SHOW AT DRESDEN.—Invitations to take part in the 3rd International Horticultural Exhibition that is to be held at Dresden, in May, 1907, have now been issued. The exhibition is so planned as to be representative of every branch of horticultural art. Orchids, which are meeting with ever increasing favour in Germany, in great measure due to the newly-founded German Orchid Society, are to receive special attention. Other sections of the exhibition are to be devoted to hot-house and cool-greenhouse plants, Palms and early spring flowers. Fruit, vegetables, open-air and aquatic plants are to have places allotted to them, and the theories of horticulture, landscape gardening, garden architecture, the construction of conservatories, and the art of the florist will meet with due consideration. Full particulars and the regulations relating to exhibitors and competitors are to be obtained from the Exhibition Office, Hotel Stadt Rom, Neumarkt 10, Dresden—A.

MR. GOODACRE.—"A visitor to New York last week was J. H. GOODACRE, a well-known English horticulturist and writer on fruit culture in the English horticultural papers. He has been spending four weeks "seeing America." On landing, he went through Canada to the Pacific Coast, travelled through California and came East, arriving in New York from Washington last Wednesday morning. In Washington, he was entertained by W. R. SMITH. He visited the Rose-growing establishments of New Jersey, and sailed from New York on the "Campania" on Saturday last. MR. GOODACRE is much impressed with the large scale on which things are carried out in the florists' business in this country, and he feels that it is a great mistake for English gardeners to come to the United States when they have once become started on their career on the other side."—*Florists' Exchange*.

PORTRAITS OF BOTANISTS.—Mr. DÖRFLER, of Vienna, announces that he is about to publish at intervals a series of portraits of botanists, accompanied by a short biographical sketch. The size of the portraits is 5 × 3 inches. Each part is to contain 10 portraits, and 100 portraits with title page and index will form a volume.

MR. JAMES DAWES, of Ledbury Park Gardens, Herefordshire, has resigned his position as head gardener for Lord BIDDULPH, a post he has filled for upwards of twenty years past, in order to take an appointment as fruit-expert and instructor under the New Zealand Government. Mr. DAWES had for several years past served as a councillor of the Ledbury Urban District Council. The council called a special town's meeting for the purpose of making some suitable form of recognition of his services. A committee was then appointed, and this committee called a meeting on Monday, July 9, at the Barratt Browning Institute, when the chairman, Mr. STEPHENS, C.C., made the presentation. We understand the purse contained upwards of fifty guineas. Mr. DAWES was well known as a most successful grower and exhibitor of all kinds of fruit at the largest exhibitions in the United Kingdom, having gained the "HOGG" Memorial Medal last October at the

FIG. 23.—CARDUUS KEENERI; FLOWERS PURPLE.

(For text see page 52.)

R.H.S. autumn fruit show. His services as judge were in great demand, for amongst other ordinary engagements he acted as judge for several years of the annual winter pruning competitions of the Worcestershire County Council. Mr. DAWES practically re-made the entire gardens at Ledbury Park; he also took the keenest interest in the technical instruction schemes of both the Hereford and Worcester County Councils.

THE WINTER FLOWERING CARNATION SOCIETY has now published its rules as adopted on May 29, from which we make the following extracts:—1. The society shall have for its object the extension of the culture and the improvement of winter flowering Carnations. (a) By holding exhibitions annually. (b) By awarding certificates to meritorious and truly "winter flowering" varieties, such certificates to be awarded by practical and experienced growers only. (c) By the collection and dissemination of information likely to prove of interest and profit to the members, and by encouraging the extended growing of these flowers. 2. The membership to be confined to trade growers and amateurs. The minimum yearly subscription to be 5s. Subscriptions become due on election, and afterwards on January 1st in each year. Copies of the rules may be obtained on application to the society's secretary, Mr. HAYWARD MATHIAS, Dean Cottage, Thames Ditton, Surrey.

FERTILISERS AND FEEDING STUFFS BILL.—The object of this Bill is to carry into effect the recommendation of the Departmental Committee appointed in 1903 by the President of the Board of Agriculture and Fisheries to inquire into the working of the Fertilisers and Feeding Stuffs Act, 1893. The Bill proposes to repeal the Act of 1893, and re-enact it with the alterations suggested by the committee. Among the provisions of the Act are the following:—"Every person who sells for use as a fertiliser of the soil any article which has been subjected to any artificial process in the United Kingdom, or which has been imported from abroad, shall give to the purchaser an invoice stating the name of the article and what are the respective percentages (if any) of nitrogen, soluble phosphates (that is to say, the actual percentage of tribasic phosphate of lime which has been dissolved or rendered soluble), insoluble phosphates, and potash contained in the article, and the invoice shall have effect as a warranty by the seller that the actual percentages do not differ from those stated in the invoice beyond the prescribed limits of error. Where any article sold for use as food for cattle or poultry is sold under a name or description implying that it is prepared from any particular substance or from any two or more particular substances, or is the product of any particular seed, or of any two or more particular seeds, and without indication that it is mixed or compounded with any other substance or seed, there shall be implied a warranty by the seller that it is pure—that is to say, is prepared from that substance or those substances only, or is the product of that seed or of those seeds only. . . . On the sale of any article for use as food for cattle or poultry, there shall be implied a warranty by the seller that the article is suitable to be used as such. . . . Any statement by the seller of the percentages of the chemical and other ingredients contained in any article sold for use as a fertiliser or the value of the nutritive and other constituents contained in any article sold for use as food for cattle or poultry, made after the commencement of this Act in an invoice of such article, or in any circular or advertisement relating to such article, shall have effect as a warranty by the seller."

LABELLING IN THE REGENT'S PARK.—A correspondent writes appreciatively of the fact that the names on the labels attached to the plants are written in a horizontal direction, so that it is not requisite to twist one's neck to read them. He also suggests that some competent person should be employed to supervise the nomenclature, and especially the spelling of the plant names. He gives a large number of illustrations in confirmation of his statement, but it is not necessary to repeat them. Few can know better than ourselves how difficult it is to avoid errors, especially when, as in our case, the work has usually to be done under pressure.

RESULTS OF GRAFTING UPON APPLES.—At a meeting in April last, of the *Société Nationale d'horticulture de France*, M. GUSTAVE RIVIERE gave the results obtained by grafting the Apple Calville blanc on the Paradise stock and upon the Doucin. It may be remembered that previous similar experiments have been made with Pears grafted on free stock and on the Quince. As regards the influence of the stock upon the scion in the case of the Apple, M. RIVIERE deduces the following conclusions:—1, The average weight of Apples gathered on Calville blanc grafted on Paradise is superior to that of Apples of the same variety grafted on Doucin; 2, The proportion of free acid (expressed in sulphuric acid S O 4 H 2), is larger in the juice of Apples gathered on the variety under consideration grafted upon the Paradise than in the juice of fruit of the same variety grafted on Doucin; 3, The proportion of ash is greater in the juice of fruits gathered from trees grafted on Doucin than in the juice of fruits gathered from trees grafted on Paradise; 4, Lastly, that the proportions of reducing sugar and of saccharose are perceptibly larger in fruits of Calville blanc grafted upon Paradise than in those of the same variety gathered from trees grafted on Doucin. These new experiences confirm those previously made, and further show, not only that dessert Apples contain more sugar per litre of juice than do Pears, but that they also contain more saccharose and more free acid.

BOLETIM DA SOCIEDADE BROTERIANA.—The last issued number of the *Transactions* of this Portuguese Botanical Society comprises a number of articles concerning the flora of that country. Some of the articles are in Portuguese, others are in French, especially one by M. J. DAVEAU on the botanical geography of Portugal, which is full of detail interesting to those who study the distribution of plants and their relation to past and present conditions.

DENDROLOGICAL SOCIETY OF FRANCE.—This society was founded in November, 1905, for the association of all interested in trees, in their botany and acclimatisation, both practical and theoretical. As regards theory the society will encourage its study by publishing in its *Bulletin* original monographs and reports of the works of non-members. It will further strive to adopt a uniform nomenclature, conformable to the rules laid down by botanists. In the practical section the wider cultivation of rare and the introduction of new species will be encouraged. The *Bulletin* will publish such facts as can be got together with regard to the use of exotic species, so as to ensure the trial and careful and rational utilisation of these for ornamental purposes or for economic plantations. For this end the cultivation of little known trees will be undertaken and the products distributed among the members. Exchanges between the members will also be encouraged. Finally, information will be at the service of the adherents of the society on questions concerning identification, cultivation, and so on. M. R. HICKEL, Professor of the National School of Agriculture le Grignon, 11 bis, Rue Champ la Garde, Versailles, is nominated secretary of the Dendrological Society; M. DODE, 4, Place du Maine, Paris, is the treasurer.

METEOROLOGY.—The council of the Royal Meteorological Society, with the view of advancing the general knowledge of Meteorology, promoting an intelligent public interest in the science, and making the work of the society more widely known, last year appointed a lecturer to act in co-operation with scientific societies, institutions, and public schools in various parts of the country. The success attending the project was so marked as to lead the council to continue the appointment for another year. An opportunity is thus presented of stimulating and directing in a scientific channel the popular interest always shown in the weather, and of obtaining authoritative information on matters regarding which the public are not always well informed. The lecturer, Mr. WILLIAM MARRIOTT, F.R.Met.Soc., is prepared to deliver lectures on the following Meteorological subjects:—1, "A Chat about the Weather"; 2, "Weather Forecasting"; 3, "Rain, Snow, Hail and Thunderstorms"; 4, "The Upper Regions of the Atmosphere"; 5, "Clouds, Fog and Sunshine"; 6, "Climate and Health"; 7, "Meteorology in relation to Agriculture"; 8, "How to observe the Weather" (Elementary). The society possesses a valuable collection of photographs, drawings, diagrams and charts, illustrating meteorological phenomena, and also various patterns of instruments used in meteorological observations. The council are willing to make arrangements for exhibiting selections of these, under the charge of a member of the staff, at gatherings of local scientific societies, or on other occasions when they are likely to prove of interest. Particulars as to the fees for the lectures, and as to the terms on which the exhibits can be lent, may be obtained from the assistant secretary, Royal Meteorological Society, 70, Victoria Street, Westminster, S.W., to whom all communications should be addressed.

GERMAN DENDROLOGY.—The 15th annual meeting of the Deutsche Dendrologische Gesellschaft (German Dendrological Society) is to take place this year at Oldenburg, from August 6 to 10. An attractive programme has been prepared, including visits to the most noteworthy parks and gardens in the vicinity under the guidance of their respective owners and superintendents. The inaugurators of the excursions state that these are to be of a purely scientific nature and are not to be looked upon in the light of ordinary summer picnics. Lectures will be given on various dendrological subjects, including monstrosities, the species of Rhus, the culture of Rhododendrons, and notes on Conifers. A small exhibition will be held in connection with the meeting. Herr THORMAN, 27, Langestrasse, Oldenburg, will be pleased to give further particulars concerning the meeting and all information respecting hotel accommodation.

HERACLEUM MANTEGAZZIANUM is one of the most imposing plants of its class. It is a native of the Caucasus, and in its finely cut, dark metallic green foliage somewhat resembles that of an Acanthus. It is best adapted for growing on turf in a somewhat shady situation. If it is planted out in the spring as a year-old seedling, it develops during the summer into a fine foliage plant of from 2 to 3 feet high. In the following year it reaches a height of over 9 feet, and the circumference is not far short of 8 feet. The large, yellowish-white flowers are arranged in umbels measuring from 12 to 15 inches across. As with all other species of Heracleum, H. Mantegazzianum, after its flowering at the end of August, ripens its fruit and soon dies down, whereupon fresh sowings should be made and the young seedlings again started. The plant in flower is figured in the *Gartner Zeitung*, May 26, from a photograph taken in the nursery of Messrs. STIEGLER BROTHERS, in Cannstatt.

PITCHER-SHAPED LEAVES.—Horn or trumpet-shaped formations on the leaves of Lettuces, Cabbages, and other plants are by no means uncommon. In a recent number of the *Comptes Rendus* (June 25, 1906), M. BLARINGHEM notes the formation of these pitchers after, and apparently in consequence of, some mutilation or injury to the plant. Further than that the observer just named has proved by experiment that the condition is in some cases hereditary. Assuming this to be correct we have an instance of inheritance of an "acquired" character.

SPRAYING POTATOS.—The New York Experiment Station publishes (in *Bulletin* No. 279) some useful directions for spraying Potatos, pointing out the uses and limitations of the operation. The writers, Messrs. STEWART, EUSTACE, and SIRRINE, conclude that "the general tendency of spraying is to reduce the amount of rot. In most cases the reduction is very marked; in some cases there is no difference, and occasionally spraying increases the amount of rot. It depends on weather conditions and the thoroughness of spraying. But whatever the effect on rot-sprayed plants always give a larger yield of marketable tubers. Judging from the experiments thus far made it appears that spraying for blight is an operation which no potato grower in New York can afford to neglect. Thirty-three farmers' business experiments made during the past three years show an average net profit of over 22 dollars per acre due to spraying. Commence spraying with Bordeaux when the plants are 6 to 8 inches high, and repeat at intervals of 10 to 14 days throughout the season, making in all five or six applications. When bugs are troublesome add Paris Green or other poison."

Publications Received.—From the Imperial Department of Agriculture for the West Indies. *Tobago, Hints to Settlers*, by Mr. J. T. Rosseau, Captain Short, and Mr. Smith. Messrs. Walker and Evans, and Savile have supplied the photographs. Cacao, Rubber and Cotton are the chief crops for planters to grow, but there are, of course, many other productions of the island.—*Manurial Experiments with Sugar-Cane in the Leeward Islands*. 1904-5. Ratoons but not plant canes showed gain from the use of artificial manures. The publication was drawn up by Dr. Watts and his colleagues.—*Agricultural Bulletin of the Straits of Federated Malay States*. March. Edited by H. N. Ridley and J. B. Carruthers. The contents deal chiefly with Rubber notes and news.—*Agricultural News, Barbados*. Contents: Canning Pines, and notes on Cassava, Cotton, &c.—*Annual Report on the Botanic Gardens, Singapore and Penang*, by H. N. Ridley. Water-lilies were established and did well, as also did Gladioli, plants seldom seen in Singapore. The work of the herbarium was carried on under difficulties owing to lack of funds. An agricultural show was organised in Penang, and proved very successful.—*Annual Report on the Forestry and Scientific Department, Uganda*. March 31st. by E. Brown. Large additions were made to the herbarium. The garden and nurseries are increasing, and much useful experimental planting was undertaken.

CARDUUS KERNERI.

THIS distinct looking plant is a member of the Thistle genus and comes from Bulgaria. It was distributed in 1905 by Herr Leichtlin, and grows from 2 to 3 feet high, with spiny stems and leaves. The large flower heads are produced singly on long peduncles, and are very attractive when in bud, owing to the rich red-purple colouring of the bracts. The flowers also are rich rosy-purple in colour, and the whole plant reminds one of our native C. cernuus, with its nodding heads of flowers. It is evidently a biennial. For the specimen illustrated we are indebted to Mr. Beamish, of Cork.

OMPHALODES LUCILIÆ.

THIS very pretty herbaceous plant, with glaucous foliage and pale blue flowers, like those of the Borage, is reputed to be difficult to grow. Those who have seen it on Mr. Crisp's rockery at Friar Park, Henley, will feel sceptical as to the difficulty we have mentioned. It has there a deep root range, and is sheltered by an overhanging mass of rock.

FIG. 24.—OMPHALODES LUCILIÆ, AS GROWN ON MR. CRISP'S ROCKERY AT FRIAR PARK.

NURSERY NOTES.

SWEET PEAS AT MESSRS. WATKINS & SIMPSON'S.

ABOUT fifty members and friends of the National Sweet Pea Society visited the seed grounds of these wholesale seed merchants at Twickenham and Feltham on 6th inst. for the purpose of inspecting a trial of about 150 varieties of Sweet Peas. The nurseries were in first-class condition, and bright patches of many flowers were in full beauty, one breadth of the vivid Eschscholtzia Mandarin being noticeable from all quarters of the seed farms. But it was with the Sweet Peas that the company had specially to deal.

The object of the trial was to ascertain the behaviour of each variety when grown under ordinary conditions; also to determine the merits of its colouring compared with others of the same shade, and, as many are known to be duplicated under other names, to identify the varieties. It was at once seen that many varieties are not nearly "fixed," and the tendency to revert is in some so great that the true type was difficult to determine in the row. The rows were apportioned to varieties of colours according to the Society's schedule—twenty-two in all. It was at once apparent that many were quite inferior to those in neighbouring rows. Many old varieties, however, were found to be still worthy a place. Thus Lord Rosebery was considered quite one of the best of the rose shades, while the old Black Knight is equal to any maroon, and Bronze King is still quite distinct, although rather small in flower. Among the pink and rose shades, Gladys Unwin appeared to be one of the best. Countess Spencer, also good of colour, was found to be much mixed. Many of the rose and pink varieties were either synonymous with or inferior to Gladys Unwin. Queen Victoria (yellow and buff) is a strong grower; and of this shade is Lady M. Ormsby Gore, which is a good shade of colour when young. King Edward VII. is one of the best of the scarlet and crimson shades. Queen Alexandra was considered an improvement on Scarlet Gem, being slightly larger and does not burn. Fascination is a good lavender and mauve. Much duplication of names was noted in this section, and some were very mixed, not having been sufficiently "rogued." Lottie Eckford is one of the best of the Picotee section. Among the "blues," Romolo Piazzani attracted attention. The new Admiral Togo (maroon) greatly resembled Othello, an old kind. Prince Edward of York is a good bicolor. Among the orange shades were some grand things. Gorgeous is admirable, and Evelyn Byatt perhaps better still. Bolton's Pink and Miss Willmott are others of merit of this shade. Among the "creams," Gracie Greenwood is first class. Among the striped and flaked, the new Helen Pierce was favourably received.

After the inspection of the Peas the party were conducted over the large nursery grounds of the firm, both at Twickenham and Feltham, and much that was interesting was gleaned as to the methods of raising seeds and stocks by our large wholesale seedsmen.

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

NAME: NAME:—In walking through Regent's Park the other day I was pleased to find a great number of labels with the names written horizontally so that one can read them without having to strain one's neck in so doing. It is rather a pity, however, that some competent person did not supervise the spelling of the names. One would expect to find botanical names spelt correctly in a Royal Park. *N.* [Our correspondent mentions a large number of illustrative examples.]

FROM A SOUTH DEVON GARDEN.—I have just returned home after six weeks' absence and find a few good things out. Androsace lanuginosa, about 4 feet square, has evidently been splendid, but is going off now. The glory of the garden is Salvia dichroa from the Atlas Mountains. It is over 8 feet in height and 6 feet through at the base, and has hundreds of flower spikes. Buddleia Colvillei is still in bloom, and B. variabilis Veitchiana is just coming into full flower. Sparaxis (Dierama) pulcherrima alba is very beautiful, having dozens of tall, slender, arching flower-stems holding drooping white blossom. It is far prettier than the type. I also have Callistemon salignus (sold by nurserymen under the name of Metrosideros floribunda) in flower, Indigofera decora alba, Psoralea pinnata (pretty), Aristæa Ecklonis, Mitraria coccinea, Philesia buxifolia, Arthropodium cirratum, a white Bouvardia, Agapanthus (blue and white), Solanum aviculare (7 feet high, good), and Bowkeria triphylla is in bud. *S. Wyndham Fitzherbert.*

FIG. 25.—OMPHALODES LUCILIÆ: FLOWERS PINK, CHANGING TO BLUE.

EARLY DWARF PEAS.—I desire briefly to pay a tribute to Little Marvel and Harbinger for affording earliest crops. These two varieties were planted on south borders here out of seed boxes on March 5. Although the spring proved anything but favourable, we had an abundant supply of Peas in the first week in June. I consider these two varieties beyond passing merit, inasmuch as they are capable of withstanding drought, and the quality of the Peas remains fit for table for a considerable time after the pods have reached maturity. We favour the method of raising early marrow Peas in boxes and transplanting small well-hardened plants during a spell of open weather. Hitherto I had regarded the taller growing William I. as an indispensable variety, but although a prodigious cropper it matures quickly and soon becomes unfit for table use on our light gravel land. *F. W. Goch, Edge Grove.*

CAMPANULA AMABILIS.—The fault possessed by Campanula amabilis of producing but few flowers, remarked upon by "W. I." in the "Kew Notes" in the *Gardeners' Chronicle* of July 14, has shown itself in other parts of the country. It is also much taller in habit than its foliage would lead one to think, and the flower spikes seem unduly tall in proportion to the plant. The foliage in itself is, however, of much beauty, and as a low-growing plant it is not to be despised, even when not in bloom. *S. Arnott, Sunnymead, Dumfries.*

ROMNEYA COULTERI.—This plant is not generally regarded as one of the easiest of cultivation, but when success is attained the result is specially gratifying. At the time of writing Romneya Coulteri is the most charming subject in this garden. Nearly two hundred flowers are open at once, and of buds there are as many again to open. Some idea may be obtained of the effect and fragrance by anyone acquainted with the Californian Poppy. Little difficulty has been experienced in cultivating the plants. It is always necessary, however, to make a good start and in a suitable site. The position chosen here is under a terrace wall having a south-west aspect. At the foot of the wall a trench 2½ feet was taken out, and a drainage of broken bricks and lime rubble to a depth of 1 foot was returned, on the top of which a very porous compost, consisting of turfy loam and road grit in equal proportions, together with plenty of finely broken brick and lime rubble, well incorporated, was placed. These conditions allow of the application of copious supplies of diluted farmyard soakage during the season of growth, but ensures a dry bottom during the resting period which is most essential. Six plants planted four years ago have each season become stronger, and this season growths 8 feet and 9 feet in length, strong, and healthy-looking, have been made. No protection from frost has been given. *A. Bullock, Coffod Hall Gardens, Essex.*

VEGETABLES FOR HOSPITAL. May I bring to the notice of the readers of the *Gardeners' Chronicle* a means whereby they may confer a great benefit to a deserving institution at no very great cost to themselves. One of the most important items of diet at this hospital is fresh vegetables, and it is one that it is very difficult to keep the hospital satisfactorily supplied with through the ordinary commercial channels. I therefore appeal to owners of gardens to be so good as to send us presents from time to time of fresh vegetables. I shall be happy to defray the cost of carriage in both directions. I might mention that as the largest children's hospital in England, and the medical school recognised by the University of London for the study of children's diseases, we receive patients and students from, and send out doctors and trained nurses to, all parts of England, so that the benefits conferred by the hospital not being confined to the inhabitants of London, I feel I may with some justification appeal to those living in the country for help. In addition I may state that in one year no fewer than 162 children of gardeners were treated at the hospital. *Stewart Johnson, Secretary, the Hospital for Sick Children, Great Ormond Street, London, W.C.*

PLANT PORTRAITS.

LOCUSTA. KATHLEEN MALLARD.—*Revue de l'Horticulture Belge*, July 1.

DENDROBIUM FORMOSUM.—*Revue Horticole*, July 1. Second-class *Gardeners' Chronicle*, June 2, 1906, fig. 138.

SOLANUM CORNIFOLIUM, *Revue Horticole*, July 1.

SOCIETIES.

ROYAL HORTICULTURAL.

JULY 17.—Only a week intervened between the holding of the great exhibition at Holland House and the meetings of the Committees at the Hall, Vincent Square, on Tuesday last, and it is not surprising, under such circumstances, that the Hall was only poorly furnished with exhibits.

The awards recommended to novelties included four Awards of Merit by the FLORAL COMMITTEE, one First-Class Certificate and two Awards of Merit by the ORCHID COMMITTEE, and one Award of Merit by the FRUIT AND VEGETABLE COMMITTEE. In the afternoon there were 59 new Fellows elected, and a lecture on "Sweet Peas" was delivered by Mr. Horace J. Wright.

Floral Committee.

Present: H. B. May, Esq., in the Chair, and Messrs. T. W. Turner, G. Reuthe, Chas. Dixon, George Gordon, W. Cuthbertson, Jas. Douglas, E. H. Jenkins, J. T. Bennett-Poe, H. J. Cutbush, Amos Perry, W. Howe, J. F. McLeod, E. T. Cook, C. Blick, R. Hooper Pearson, C. T. Druery, R. W. Wallace, and James Hudson.

An interesting exhibit of insectivorous plants came from the gardens of R. I. MEASURES, Esq., Camberwell, S.E. (gr. Mr. J. Smith), and, considering they were grown so near to the City of London, they showed very good culture. We have seen larger and stronger plants, but these were clean and healthy-looking specimens. Sarracenias, Darlingtonias, Dro-eras, Cephalotus, with a setting of Maranta Massangeana, formed the chief subjects. (Silver Flora Medal.)

Mr. JAMES DOUGLAS, Edenside, Great Bookham, Surrey, had a superb display of cut Carnations in vases. No fewer than 60 varieties were shown, and several new varieties were included (see Awards). Viscountess Ebrington (apricot yellow), Goldfinch (apricot—a glorious colour), Daffodil (yellow), Liberté (yellow ground, fancy, with brown and chocolate bars—a large and shapely flower), Bendigo (heliotrope), and Agnes Sorel (Clove) is a selection of the choicer kinds displayed.

A curious seedling Picotee was shown by Mr. DOUGLAS. The habit is tufted, with remarkably fine foliage of a pronounced glaucous tint. The flower (of a yellow shade) is small and straggling. (Silver Flora Medal for the group.)

Mr. H. B. MAY, Dyson's Lane Nurseries, Upper Edmonton, showed small plants of Ferns in several varieties, and a very large number of Codiæums (Crotons), arranged in a setting of choice Ferns. (Silver-Gilt Banksian Medal.)

Mr. C. W. BREADMORE, Winchester, put up one of the finest displays of Sweet Peas we have seen. The stand contained 145 bunches, in about 70 varieties, including novelties. All the flowers were of large size, and were presented in first-class condition, colour and substance being of a high order of merit. (Gold Medal.)

Mr. WM. DEAL, Brooklands, Kelvedon, Essex, showed many varieties of Sweet Peas representative of most of the popular shades of colours seen in these refined flowers.

Messrs. WM. CUTBUSH & SONS, Highgate, London, N., showed a remarkably pretty stand of Carnations of tree, border, and "Malmaison" types. The flowers were finely developed, and were displayed on tall stiff stems. (Silver Flora Medal.)

Mr. AMOS PERRY, Winchmore Hill and Enfield, Middlesex, staged a large bank of hardy flowers. We noticed several good forms of Chrysanthemum maximum, also a list of other showy flowers. (Silver Banksian Medal.)

Messrs. R. WALLACE & Co., Kilnfield Gardens, Colchester, showed a beautiful group, representative of most of the hardy flowers now in season. Anthemis Kelwayi resembles a clear yellow Marguerite, the flowers being produced in profusion. A good form of Mimulus cupreus named Brilliant attracted attention; the colour is deep orange-red. (Silver Flora Medal.)

Mr. MAURICE PRICHARD, Christchurch, Hants, staged a group which was brilliant with showy Campanulas, Spiræas, Delphiniums, Phloxes, Galegas, Helenniums, Pyrethrums, and other garden flowers. The Spiræas were a feature, S. palmata being finely coloured. (Silver Banksian Medal.)

Messrs. A. & G. CLARK, LTD., Dover, Kent, staged an array of border flowers and vases of Sweet Peas. (Silver Flora Medal.)

Messrs. J. CHEAL & SONS, Crawley, Sussex, also showed hardy flowers and Sweet Peas.

Some nice border Carnations were displayed by S. MORRIS, Esq., Wretham Hall, Thetford (gr. Mr. G. Henley). (Silver Banksian Medal.)

Messrs. R. & H. BATH, LTD., Wisbech, showed a mixed collection of flowers. They had some very beautiful Roses, Sweet Peas in great variety, and a number of hardy flowers.

Messrs. WM. PAUL & SONS, Waltham Cross, Herts., displayed baskets of large Roses from the open. Such beautiful varieties as Dr. Wm. Gordon, Countess Cairns (a somewhat loose flower, but of exquisite colour), Earl of Warwick, Celia, and David R. Williamson found a place in the group, which also included an arch decorated with Waltham Rambler.

Mr. HOWARD H. CRANE, 4, Woodview Terrace, Highgate, London, N., showed bunches of the small-flowered type of Pansy named Violettas. These miniature forms were nearly all named varieties raised by Mr. CRANE. They are very fragrant, have a close tufted habit, and exhibit most of the shades of colour familiar in ordinary Violas.

Messrs. J. BURRELL & Co., Howe House Nurseries, Cambridge, showed seedling Rudbeckias.

Messrs. DOBBIE & Co., Rothesay and Mark's Tey, showed a batch of Godetia Schamini, a beautiful hardy annual, the plants being raised from autumn-sown seed. An individual plant, included to show the habit, was smothered with its semi-double, rosy-pink flowers. The variety was awarded an Award of Merit last season.

MARY Countess of ILCHESTER, Holland House, London, W. (gr. Mr. Dixon), showed sprays of Petræa volubilis, Hibiscus brilliantissimus, and Ipomœa Learii.

LEOPOLD DE ROTHSCHILD, Esq., Gunnersbury House, Acton, exhibited a number of small plants of Lisianthus Russellianus, each with a showy inflorescence to show its identity with the plant given an Award at the Holland Park Show. An illustration of the plant is given at fig. 26.

Flowers of Romneya Coulteri were displayed by Mr. W. A. Cook, gardener to Sir EDMOND LODER, Leonardslee, Sussex. The individual flowers were very big, and resembled large, white, single Paconies.

Nymphæas of exceptional quality were displayed by Lord HILLINGDON, Hillingdon Court, Uxbridge (gr. Mr. A. Allen). There were large flowers of the beautiful claret-coloured variety William Falconer, Lucida (of lighter tint), carnea (as its name suggests delicate flesh tint), the tiny pygmea alba, the yellow chromatella, and others of equal beauty. (Silver Banksian Medal.)

Messrs. H. CANNELL & SONS, Swanley, Kent, displayed some little pot plants of the floriferous Nemesia strumosa. The specimens were of very compact growth, and each was covered with a profusion of flowers. The range of colouring in the flowers was very wide, the strain being exceptionally good and much in advance of the older type, some of which were included for comparison. Messrs. CANNELL also showed a plume of the Woad Isatis glauca, with flowers of a rather better shade of yellow than is usually seen in this plant.

AWARDS OF MERIT.

Carnation Cupid.—A clear, rich pink-coloured border variety, of moderate size, excellent form, and non-splitting calyces. The petals are very slightly fimbriated. Shown by Mr. JAMES DOUGLAS.

Carnation Robert Berkley.—A brilliant, rosy-crimson border variety; the flowers are of large size, and rather too crowded in the centre, giving to the variety an appearance suggestive of a Hollyhock. Shown by Mr. JAMES DOUGLAS.

Delphinium "Cinos."—A white or sulphur-coloured variety, with primrose-yellow centre. The flowers are very large and of good form, and they are produced on large, bold, well-furnished spikes. Shown by G. FERGUSON, Esq., The Hollies, Weybridge (gr. Mr. F. W. Smith).

Sweet Pea "Rosy Morn."—A deep reddish-rose or magenta-coloured variety. The flowers are extra large, and the standard erect and spreading, though slightly wavy. The spikes had three flowers on each. Shown by Messrs. H. CANNELL & SONS.

Nemesia "Orange Prince."—This strain has two qualities to recommend it. The first is that of good habit, the plants shown being about 7 inches in height, perfectly erect, branching from the base—from axils below the ground level—and presenting an almost level surface of bloom 9 inches across. The second good quality is in the rich orange shade of the flowers, which showed no variation in the four plants submitted to the committee. The habit, especially, is much to be preferred to some Nemesias. The variety was shown by Mr. W. H. GARDNER, Mill Street, St. Osyth (Award of Merit for strain.)

Orchid Committee.

Present: J. Gurney Fowler, Esq. (in the chair), and Messrs. Jas. O'Brien (hon. sec.), H. J. Veitch, De B. Crawshay, W. A. Bilney, J. Colman, H. A. Tracy, W. H. White, W. H. Young, H. G. Alexander, W. Boxall, and H. Little.

Messrs. HUGH LOW & Co., Enfield, were awarded a Silver Banksian Medal for a group of Orchids, in which were some good varieties of Cattleya Mossiæ and C. Mendeli, one specimen of the former bearing 17 flowers; also a very large-flowered C. Gaskelliana; another pretty variety of it with uniformly tinted pale lilac rose flowers, and the clear white C. Gaskelliana alba; C. Harrisoniana with 12 flowers, and the pure white C. Harrisoniana alba with two blooms. Others in the group were Ladio-Cattleya Ingrami, Odontoglossum Schleiperianum citrinum, and four plants of Messrs. Low's importation of O. Pescatorei, all with large round flowers of fine quality.

Messrs. STANLEY & Co., Southgate, were awarded a Silver Banksian Medal for a neat group, in which were good Cattleya Mendeli, and a selection of very fine varieties of C. Aclandiæ; a good example of C. Dowiana aurea, two plants of a natural hybrid between C. intermedia and C. guttata, with pretty flowers having whitish sepals and petals spotted with purple, and with dark purple front and tips to the side lobes of the lip, &c.

Major G. L. HOLFORD, C.I.E., C.V.O., Weston-birt, Tetbury (gr. Mr. H. G. Alexander), showed a collection of cut flowers of very fine Sobralias, one stand having five immense purplish rose blooms of Sobralia Holfordii, the labellums of which were 4½ inches across and which secured a First Class Certificate at Holland House. Four fine blooms of the handsome Sobralia Sanderiana, with white sepals and petals tinged with rose and yellow, the large labellums being reddish claret colour in front and with a rich yellow tube. Sobralia macrantha Kienastiana, which received a First Class Certificate, June 9, 1891, was represented by a stand of five pure white blooms, Sobralia Amesiana, with large yellowish flowers tinged with rose, and another variety were also shown.

J. GURNEY FOWLER, Esq., Glebelands, South Woodford (gr. Mr. J. Davis), showed Cypripedium Mrs. Rehder Glebelands variety (Argus × Rothschildiana), &c.

C. G. NEWKIRCHNER, Uplands Road, Hornsey, sent a plant of the dwarf Oncidium pumilum with an erect inflorescence of small yellow flowers.

R. J. MEASURES, Esq., Cambridge Lodge, Camberwell, sent Cypripedium Wottonii callosum

FIG. 26.—EUSTOMA (LISIANTHUS) RUSSELLIANUM: FLOWERS VIOLET PURPLE WITH ORANGE-COLOURED ANTHERS.

× bellatulum), with well-formed rose-tinted flower bearing some purple spots on the petals; Selenipedium nitidissimum, and another Selenipedium of the S. longifolium section.

Messrs. Duchesne, Lanthorne & Co., Watermael, Brussels, showed a handsome Odontoglossum which they had bought as O. caliginosum (crispum × Pescatorei), but which was identified as a form of O. Vuylstekei. The finely formed flowers were white: the sepals and petals heavily blotched with rose and the rounded fimbriate lip having the front occupied by one large brownish blotch around which was a narrow white margin.

AWARDS.

First Class Certificate.

Aerides Houlletianum Fowler's variety, from J. Gurney Fowler, Esq., Glebelands, South Woodford (gr. Mr. J. Davis). One of the finest of Aerides, large-flowered, fragrant and of attractive colouring. The heavy raceme bore many fine flowers, the sepals and petals of a pale buff-yellow tint tipped with rose; the broad labellum, white at the base, the fimbriated front of a clear rose-purple. The plant was excellently well-grown and the flowers finely developed.

Award of Merit.

Lycaste tricolor albens, from J. Bradshaw, Esq., The Grange, Southgate (gr. Mr. G. G. Whitelegge). A singularly variable little species from Guatemala, the flowers varying from greenish with rose-tinged petals to nearly white as in the variety shown, which had very pale-green sepals and petals and lip.

Cattleya Mrs. Myra Peeters (Gaskelliana alba × Warneri alba), from M. A. A. Peeters, St. Gilles, Brussels. One of the very finest pure white Cattleyas. The Award was made at the Holland House show, but a flower for painting not being then available the Award was held in abeyance. The flower had now been received.

Cultural Commendation.

To Mr. G. G. Whitelegge (gr. to J. Bradshaw, Esq., The Grange, Southgate), for two plants of Lycaste tricolor, the one with 16 and the other with 24 flowers.

Fruit and Vegetable Committee.

Present: A. H. Pearson, Esq. (chairman), and Messrs. Jos. Cheal, S. Mortimer, Alex. Dean, A. R. Allan, J. Davis, H. J. Wright, F. Q. Lane, P. D. Tucker, J. Jacques, J. Mc. Indoe, and E. Beckett.

Such a display of vegetables was shown by Mr. Ed. Beckett (gr. to Lord Aldenham, Aldenham House, Elstree,) as is seldom equalled. Not only was the quality of the produce of sterling merit, but the manner of staging showed how vegetables should be displayed. As a background were pyramids of Cauliflowers in a setting of Parsley, and beneath were clumps of Lettuce and Cabbage, with Marrows between them; in front of these were Carrots, Turnips, Beans, Potatos, followed by Beans, Peas, Tomatos, Cucumbers, Mushrooms, &c. Of Peas there were Duke of Albany, Centenary, Peerless Marrowfat, Early Giant, and Ideal; Potatos Sharpe's Victor, Ninety-fold, Ideal, Windsor Castle, Gladiator, Herd Laddie (blue), &c., all with skins of spotless exterior, and as though polished; the Cabbages included Flower of Spring, Mimcrop, and Favourite, each perfectly formed, with solid centres; Cucumbers, straight and long of the kinds Matchless, Peerless, and Delicacy; Yellow Perfection and White Gem Turnips; Intermediate Carrots; Globe Beet; Ne Plus Ultra Beans, and a host of other good things that we have not space to enumerate. (Gold Medal.)

Another meritorious display was a very large exhibit of fruit shown by Lord Hillingdon, Hillingdon Court, Uxbridge (gr. Mr. A. Allan). Here again was seen produce of excellent quality, but the dishes were spread along a table like slates on a school desk, whereas they could have been grouped with a few ornamental plants and have made a really first-class exhibit. Great variety was seen, including Peaches—Violette Hative was in first-class style; Nectarines Pitmaston Orange, Dryden; Pine Apple; Strawberries British Queen, Waterloo (good box), Trafalgar, Gunton Park; Figs Brown Turkey, Bourjassotte grise and Negro Largo; Cherries Emperor Francis, Governor Wood, Bigarreau Napoleon, &c.; also Gooseberries, Currants, Raspberries, &c. (Hogg Memorial Medal.)

A box of Condor Peaches shown by the Earl of Darnley, Cobham Hall, Kent (gr. Mr. T. R. Cuckney), was awarded a Cultural Commendation.

Mr. W. A. Cook (gr. to Sir Edmund Loder, Leonardslee, Sussex), showed fruiting sprays of Norwich Wonder and Semper Fidelis Raspberries.

Mr. W. Deal, Kelvedon, Essex, exhibited pods and fruiting haulms of popular sorts of culinary Peas.

Other exhibits included a seedling Melon, varieties of Cucumbers, and a new Rose Potato.

Award of Merit.

Culinary Pea "Quite Content."—This Pea, pods of which were shown by Messrs. J. Carter & Co., was mentioned in a previous number as being grown at Wisley. The pods are extremely large, and some of them contain as many as eleven first-class Peas. The variety is described as the best mid-season Pea up to date, but even so, gardeners are not apt to remain "quite content" for long, and they will be likely still to look for further improvement in Peas.

THE AFTERNOON MEETING.

At the afternoon meeting there were fifty-nine new Fellows elected, and Mr. Horace J. Wright delivered a lecture on Sweet Peas, Mr. C. H. Curtis presiding. Mr. Wright commenced by stating that the Sweet Pea could never have been a common flower, and related what a very long Latin name it originally bore. He mentioned its introduction from Sicily to this country to Dr. Uvedale, the raiser of Uvedale's St. Germain Pear, towards the end of the 17th century; also the slow development that occurred until the late Mr. Henry Eckford set to work about 30 years ago, the results of which are familiar to our readers. Six or seven years ago, Mr. Silas Cole, gardener to Lord Spencer, showed the variety Countess Spencer, a variety with a wavy standard of much beauty. From this variety very many others have arisen with similar characteristics, and, although all of these are at present very variable, Mr. Wright said he believed that this type would be favoured in the future beyond the giant type with erect standard such as was raised by Mr. Eckford. Reference was made to the National Sweet Pea Society, and Mr. Wright said that the society should have some regard at least for varieties that are specially suitable for garden decoration, and not, as at present, devote its entire attention and interest to the exhibition qualities in the flowers. It might not generally be known that if Sweet Peas are cut part way down after flowering they are capable of producing another display. This they will do, if plenty of water and manure water is afforded them. After a few remarks by Mr. Curtis, Mr. Alex. Dean said he hoped that efforts would not be made to obtain four or more flowers on a spike. They were prettier in clusters, than in spikes like the perennial species, and when many are produced on the same spike, the older flowers cease to be attractive before the uppermost ones expand.

WOLVERHAMPTON FLORAL FETE.

GREAT SHOW OF ROSES.

July 10, 11, 12.—The eighteenth annual Floral Fête, held in the well-kept West Park, Wolverhampton, now radiant with flowers, was a great success. Among flowers deserving special mention, reference may be made to the remarkably fine displays of Roses, which were the best ever seen at Wolverhampton. The success of Messrs. B. R. Cant & Sons, of Colchester, was most pronounced. They took six first prizes in the open classes. In the section devoted to specimen and miscellaneous plants (open) Messrs. Jas. Cypher & Sons, of Cheltenham, won four first prizes. The Sweet Peas shown by Mr. T. Jones, of Ruabon, surprised and delighted all who saw them.

In the non-competitive section, the exhibit of Messrs. Baker's, of Codsall, will long be remembered as the best of its kind ever attempted at Wolverhampton.

Upwards of 50,000 square feet of space was under canvas, each tent being connected by means of corridors. Rain fell about 11 o'clock on the opening day, and again very heavily in the afternoon. Great praise is due to the various officials responsible for the working of this important exhibition, for which about a hundred more entries were received than last year.

Plants (Open).

The principal class was for a group arranged for effect on a ground space not exceeding 350 square feet, for which prizes amounting to £57 10s. were offered, and for which entries were received from four competitors, whose exhibits were placed down the centre of a tent specially reserved for them. The groups were all constructed on pretty much the same principle, i.e., a tall mound in the centre crowned with a Palm, and at each of the four corners smaller mounds. The premier prize of £25 was awarded to Messrs. Jas. Cypher & Sons, Queen's Road, Cheltenham, whose group was beautifully arranged, and contained a selection of plants and cut-flowers of such things as Phalænopsis, Odontoglossums, delicately-coloured Cattleyas, Onciiums, Clerodendron fallax, Liliums, highly-coloured foliage plants, graceful Aralias, tall Jacarandas, Palms, Ferns, and silver-leaved Grasses, the whole being edged with Caladium argyrites and Saxifraga sarmentosa superba. The 2nd prize was won by a new competitor, Mr. W. Holmes, West End Nurseries, Chesterfield, for an artistically-arranged, but rather thin, group, in which light and yellow-coloured foliage plants were used with good effect. Mr. W. Vause, Leamington, and Mr. W. Manning, Derby, also obtained prizes in this class.

A class for twelve stove and greenhouse plants, not fewer than six to be in bloom (Orchids excluded), only brought three competitors. Here again Messrs. Jas. Cypher & Sons carried off the leading prize of £15 with superb Statices, Ixoras, &c. 2nd, Mr. W. Vause, with smaller plants not nearly so well flowered.

The best six exotic Ferns came from J. A. Kenrick, Esq., Berrow Court, Edgbaston (gr. Mr. A. Cryer).

The principal specimen plant class was for twenty plants grown in pots not exceeding 8 inches in diameter. Eight, at least, were to be in bloom. Messrs. Jas. Cypher & Sons and Mr. W. Vause were the only exhibitors. The 1st prize of £10 was easily won by Messrs. Cypher & Sons, who had eighteen plants in flower and two large richly-coloured broad-leaved Codiæums. The flowering plants were Ixora Williamsi (4), I. Pilgrimi (1), I. Fraseri (1), Allamanda Williamsi (2), Chironia ixifera (3), Statice intermedia (3), Begonia Gloire de Lorraine (2), and Clerodendron fallax (2).

For a group of one class of flowering plants, arranged on the ground in a space of 9 feet by 5 feet, only two exhibitors competed. The 1st prize was awarded to H. Lovatt, Esq., Low Hill, Bushbury (gr. Mr. R. Sharpe), for well-flowered Cannas; the plants were about 2 feet high, and grown in small pots. 2nd, B. H. Mander, Esq., Trysull, Wolverhampton (gr. Mr. C. Weaver), with a bright display of Clerodendron fallax.

For a group of tuberous Begonias, arranged for effect on a table 10 feet by 5 feet, there were four exhibitors, and last year's winner, Mr. F. Davis, of Pershore, easily won the 1st prize with a grand lot of double varieties, some of the flowers measuring 6 inches across.

The 1st prize of £6 offered for the best six Orchids in flower was easily won by Messrs. Jas. Cypher & Sons.

Roses (Open).

Roses were particularly good, and quite a show in themselves. The principal class was for seventy-two distinct varieties, for which £42 was offered. Five competitors entered, and after a very close contest Messrs. B. R. Cant & Sons, Colchester, were awarded the 1st prize of £20. The blooms of Duke of Wellington, Le Havre, Hugh Dickson, Madame Victor Verdier, Alfred Colomb, Souvenir d'Elise Vardon, Frau Karl Druschki, and Suzanne Marie Rodocanachi were of perfect shape and quality.

For forty-eight distinct varieties, Messrs. B. R. Cant & Sons were also first, with superb flowers of Mildred Grant, Dean Hole, Dupuy Jamain and Ulrich Brunner, &c., and first for twelve distinct varieties, three blooms of each.

There were four exhibits of twelve bunches of

Roses to be shown, with foliage and buds as cut from the plants, each bunch to contain not fewer than three spikes or stems. Mr. J. MATTOCK, Oxford, won the 1st prize with the varieties Liberty, Anna Olivier, Comtesse de Nadaillac, Marie Van Houtte, Kaiserin Augusta Victoria, Madame Ravary, Papillon, Prince de Bulgarie, Frau Karl Druschki, Madame Abel Chatenay, Mrs. W. J. Grant, and Clara Watson.

The 1st prize, consisting of a gold medal and £2, for a dozen Roses put into commerce during the years 1903-4-5, fell to last year's winners, Messrs. A. DICKSON & SONS, Newtownards, with superb blooms, the most meritorious varieties being Mrs. Bateman, Dean Hole, Hugh Dickson, and Lady Ashtown; 2nd, Mr. HUGH DICKSON, Belfast, whose flowers were almost as fine as those from Messrs. A. DICKSON & SONS.

The best dozen blooms of any light-coloured Rose came from Messrs. B. R. CANT & SONS, who staged shapely flowers of Mildred Grant; 2nd, Messrs. D. PRIOR & SON, with Bessie Brown. So good and so numerous were the flowers staged in this class, that the judges awarded an extra prize to Mr. GEO. PRINCE for a grand exhibit of Mildred Grant. Messrs. B. R. CANT & SONS showed the twelve finest dark Roses, having the variety Horace Vernet.

The best dozen distinct varieties of Tea Roses came from Mr. GEORGE PRINCE.

For nine distinct varieties of Teas and Noisettes staged in vases, five blooms of each, on a space of 5 feet by 3 feet, Messrs. D. PRIOR & SON won the 1st prize, and Mr. G. PRINCE the 2nd prize.

Nine bowls of Roses were staged, the best being from Messrs. PERKINS & SONS, of Coventry, Mr. J. BARROW being 2nd.

Competition was also keen in the class provided for vases of cut Roses. 1st, Mr. J. BARROW; 2nd, Mr. W. J. GARNER.

In classes reserved for amateurs, we noted the names of Rev. J. H. PEMBERTON, Havering-atte-Bower; R. F. HOBBS, Worcester; F. DENNISON, Kenilworth; and others among the leading prize takers.

BOUQUETS AND CUT FLOWERS (Open).

Messrs. PERKINS & SONS, Coventry, took 1st prize for Bridal, Bridesmaids', and a bouquet for the hand, Mr. W. J. GARNER, Hale, being 2nd in each case.

For the most effectively-arranged group of decorative plants and cut-flowers on staging 6 feet by 4 feet, Mr. W. FINCH, Coventry, beat C. T. MANDER, Esq., Compton (gr. Mr. J. S. Simpson), his only opponent. The winning group contained beautiful Gloxinias, Cattleyas, and Anthuriums.

The finest collection of hardy border flowers shown in competition came from Messrs. G. GIBSON & Co., Bedale, who covered a space of 15 feet by 5 feet with a magnificent exhibit, in which were huge bunches of Delphiniums, Phloxes, Iceland Poppies, Campanulas, Gaillardias, Pæonies, Liliums, and Spanish Irises.

A Silver Cup, value £5 5s., and £20 in cash was well won by the LEAMINGTON NURSERYMEN & FLORISTS Co., Leamington, with a pretty group of foliage and flowering plants, intermingled with cut Cattleyas, Oncidiums, Carnations, &c.

Three prizes, amounting to £9 10s., were offered for arrangements of Pansies and Violas on a space of 7 feet by 3 feet. Six exhibits were staged, and Mr. J. E. KNIGHT, Wolverhampton, was placed 1st, with flowers displayed in vases and rustic stands.

Two classes for dinner table decorations were provided, one open and the other confined to amateurs. The leading prize of £5 in the first-named class was secured by Mr. W. J. GARNER, Hale.

SWEET PEAS.

Sweet Peas were extensively shown, the exhibits from Mr. T. JONES, of Ruabon, being remarkable for quality, variety, and freshness. For eighteen varieties, Mr. T. JONES gained the 1st prize, and W. D. WINTERBOTTOM, Esq., Derby (gr. Mr. G. Brown), was 2nd.

Prizes offered by Mr. H. Eckford, of Wem, Salop, for twelve varieties went as follow:—1st, Mr. T. JONES; 2nd, Lord HATHERTON, Penkridge (gr. Mr. H. Taylor).

The strongest competition was in the class provided by Mr. Robert Sydenham, of Birmingham, who offered, in addition to cash, a large gold medal for the best display of twelve distinct varieties. The winner was Mr. A. G. HOLFORD, Eccleshall, with superb flowers borne on strong stems.

Mr. T. JONES carried off the 1st prize offered by Messrs. Baker's, Wolverhampton, for six varieties.

PLANTS (Amateurs).

For a group of plants in or out of flower, arranged for effect on a space not to exceed 300 square feet, entries were received from three exhibitors. The 1st prize of £10 was well won by J. A. KENRICK, Esq., Berrow Court, Edgbaston (gr. Mr. A. Cryer), whose group contained some richly-coloured foliage plants and choice flowering subjects admirably arranged.

J. A. KENRICK, Esq. (gr. Mr. A. Cryer), had the best six specimen stove and greenhouse plants and best collection of twelve Begonias.

Four groups of Caladiums were shown, and H. LOVATT, Esq. (gr. Mr. R. Sharpe), was awarded the 1st prize. C. MARSTON, Esq., Compton (gr. Mr. W. E. Wall), staged the best collection of Gloxinias.

FRUIT AND VEGETABLES.

Fruit was shown in splendid condition, and the competition between the winners of 1st and 2nd prizes in the principal classes was very keen.

The 1st prize in a class for a collection of eight dishes of fruit was won by the Earl of HARRINGTON (gr. Mr. J. H. Goodacre), with a magnificent lot, showing very high culture, his Black Hambro', Muscat of Alexandria Grapes, Violet Hative and Royal George Peaches, Pine Apple and Early Rivers Nectarines were of very fine quality. 2nd, Lord SAVILLE, Rufford Abbey (gr. Mr. J. Doe).

The best four bunches of grapes in distinct varieties were shown by Mr. J. DOE, with heavy bunches of Buckland Sweetwater (probably 5 lb. each, but lacking in colour), Muscat of Alexandria, Madresfield Court, and Black Hambro'.

Lord SAVILLE won the 1st prize for two bunches of black Grapes with finely-coloured fruit of Madresfield Court.

Lord SAVILLE won the 1st prize for two white bunches with Muscat of Alexandria.

The Earl of LATHOM (Ormskirk (gr. Mr. B. Ashton), won the 1st prize for Peaches and Nectarines, with five fruits of Gross Mignonne and Pine Apple.

Lord SAVILLE had the best Melons with Royal Jubilee and Sutton's Scarlet.

The 1st prize in a class for collection of six dishes of fruit (gentlemen gardeners only) was won by Mr. J. H. GOODACRE.

The 1st prize in the special class for vegetables in which the prizes were offered by Messrs. SUTTON & SONS, Reading, was won by Lord ALDENHAM, Elstree (gr. Mr. E. Beckett).

The Earl of CARNARVON (gr. Mr. J. Read) won the 1st prize for a collection in Messrs. WEBB & SONS' class.

MISCELLANEOUS EXHIBITS.

From Messrs. WEBB & SONS, Stourbridge, came an attractive display of indoor flowering plants and hardy border flowers. The centre of the group was composed of Gloxinias, and on either side were some lovely Sweet Peas and fragrant Stocks. A pretty background was afforded by the use of Liliums, Hydrangeas, and Delphiniums. (Silver Medal.)

Mr. ROBERT BOLTON, Warton, Carnforth, showed 30 vases of lovely Sweet Peas, some of which are new. (Silver Medal.)

Messrs. DICKSONS, Chester, contributed an extensive and well-arranged group of border flowers and Roses. The first-named were represented by bold clumps of Pæonies, Gladioli, Dianthus annulatus, stately Delphiniums, and splendid flowers of Romneya Coulteri. (Gold Medal.)

A collection of Violas arranged in sprays came from Mr. H. PATTISON, Cherry Orchard, Shrewsbury. (Silver Medal.)

Messrs. E. & H. SUCKLING, Lichfield Street, Wolverhampton, sent floral devices. (Silver Medal.)

The largest, brightest, and most meritorious non-competitive exhibit came from Messrs. BAKER'S, of Codsall and Wolverhampton, who had wonderful collections of Roses, Sweet Peas, Zonal Pelargoniums, herbaceous and Alpine plants. The Roses were shown in boxes, large vases, and bamboo stands. Next to the Roses were some exceedingly good Sweet Peas, and a collection of hardy cut flowers and Alpine plants in great variety. In addition to a Gold Medal, a Silver Bowl and Certificate of Merit were unanimously awarded to Messrs. BAKER'S for this instructive and pretty exhibit.

Mr. JOHN E. KNIGHT, Tettenhall, Wolverhampton, showed a miscellaneous group, consisting largely of hardy flowers, Caladiums, and Bamboos.

Mr. CHARLES HOLDEN, Butt Lane, Hinckley, sent Sweet Peas. (Bronze Medal.)

Mr. A. Webster, chief of the West Park, Wolverhampton, exhibited, on behalf of the WOLVERHAMPTON BATHS & PARKS COMMITTEE, a large semi-circular group of indoor foliage and flowering plants, the leading features of which were Cannas, Schizanthus, Liliums, Gloxinias, Pancratiums, Petunias, and Campanulas. (Gold Medal.)

Mr. RICHARD LOWE, Tettenhall Nurseries, Wolverhampton, sent foliage and flowering plants. (Bronze Medal.)

Messrs. HEWITT & Co., Solihull, Birmingham, furnished a table with a good selection of hardy flowers and cut Roses. Amongst the first-named were noted very fine clumps of Japanese Irises, Œnothera Fraseri, Campanulas, and Lilies. (Silver Medal.)

Mr. JOSEPH LAMBERT, Dalmeny, Southport, exhibited silvered table decorations, in which were placed Carnations, Sweet Peas, etc. (Bronze Medal.)

Mr. ROBERT SYDENHAM, Birmingham, also had rustic table decorations and Sweet Peas. (Silver Medal.)

Messrs. SUTTON & SONS, Reading, sent miscellaneous flowering plants; also Melons, and some excellent dishes of Tomatos, Cucumbers, and culinary Peas. (Gold Medal.)

Two dozen sprays of Zonal Pelargoniums, four boxes of lovely Roses, some Sweet Peas, and new Centaureas were contributed by Messrs. JARMAN & Co., Chard, Somerset. (Silver Medal.)

Messrs. TOM B. DOBBS & Co., Wolverhampton, constructed a model garden on the lawn. Beds filled with flowers, the paths edged with rock, over which arches clothed with Roses, were admired by many visitors. (Gold Medal and Certificate of Merit.)

Mr. C. H. HERBERT, Arock's Green, Birmingham, sent Carnations and Pinks nicely arranged in bamboo stands. Here a new strong-growing Pink named Progress was noted, with large, shapely, light rose-purple flowers marked with crimson near the base of the petals. (Bronze Medal.)

A miscellaneous group of indoor plants, cut flowers, and hardy shrubs came from Messrs. CLIBRAN & SONS, Altrincham. "Malmaison" and Tree Carnations were fresh and good, and plants of the gold and silver-leaved Aralia sinensis were effective. (Silver Medal.)

Messrs. WALTER KNIGHT & Co., Bradmore, staged an assortment of flowering plants and cut flowers. (Silver Medal.)

CAMBRIDGE HORTICULTURAL.

JULY 10.—The annual summer exhibition of this society was held on the above date, in the grounds of King's College, than which a more ideal place for a horticultural gathering could not well be found. All the classes were well filled and it was considered the best show that the society has held.

Roses.—Very liberal prizes were offered in the Rose classes, especially in that for thirty-six blooms, distinct, in which Messrs. BURRELL & Co., of Cambridge, were placed 1st, with a remarkably well-grown lot. 2nd, Messrs. F. CANT & Co., Colchester. Messrs. BURRELL also won in the class for twenty-four blooms, distinct, and for twelve Tea and Noisette varieties; Messrs. CANT & Co. being 2nd in both classes. The successful exhibitors in the district classes were Messrs. DOBBS, MILLER, Rev. O. FISHER, and Mr. T. W. Birkinshaw (gr. to Sir CHARLES HAMILTON, Bart., Hatley Park).

Miscellaneous Cut Flowers.—Cut flowers of hardy plants formed a glorious display. Mr. R. W. HALL won 1st prize with a splendid collection of eighteen varieties, while for twelve varieties Mr. W. PETERS gained 1st honours. Classes for annuals was a charming feature, the 1st prize in the largest class fell to Mr. T. TOPP, while Mr. R. W. HALL won a similar

places for six varieties. The 1st prize for twelve Irises was won by Mr. J. CATLING.

Plants.—The groups of plants were arranged in a pleasing manner, prizes being taken by Mr. W. P. NEAL, Mr. J. KIRKPATRICK, and Dr. BOND in the order named. Tuberous-rooting Begonias were grandly shown, Dr. BOND gaining 1st honours in the largest class; 2nd, Mr. T. DIGGLE. Mr. L. WARREN was 1st for six Begonias, while the best six double varieties were shown by Mr. R. J. FULLER. The premier award for six foliage plants went to Mr. A. HARDING; 2nd, Dr. SANDYS. The best six plants suitable for table decoration were shown by Mr. T. TODD; 2nd, Mr. W. P. NEAL. Of great excellence were the tables of plants arranged for effect. The 1st prize was awarded to Mr. J. KIRKPATRICK; 2nd, Dr. SANDYS.

Fruits and Vegetables.—Mr. T. W. BIRKINSHAW obtained premier honours in the class for six dishes of dessert fruits, the collection including remarkably good Nectarines, Peaches, Tartarian Cherries, the Earl's Favourite Melon, Royal Sovereign Strawberries, and good clusters of Black Hambro Grapes; 2nd, Mr. T. DIGGLE. Mr. T. W. BIRKINSHAW won the 1st prize in the class for a stand of Grapes, showing a fine bunch of Foster's Seedling, weighing upwards of 5 lbs., and having well-finished berries. Dr. BOND was first for a single dish of Peaches. Mr. T. W. BIRKINSHAW gained the 1st prize for a superb dish of Early Rivers Nectarines. The prize for a collection of eight kinds of vegetables was awarded Mr. T. TODD; 2nd, T. DIGGLE.

HANLEY FLORAL FETE.

JULY 4 AND 5.—The tenth annual floral exhibition, held under the auspices of the Borough Corporation of Hanley, Staffordshire, took place on these dates in the public park and resulted in the finest display of garden produce ever seen at Hanley. The number of entries was 497, as against 431 in 1905. The increase was accounted for by the greater number of Roses. Specimen plants were not largely represented, but groups for effect and smaller plants were staged in fine condition. Specially meritorious were the displays of Roses, the competition in these and in the fruit classes being very keen. The displays of Sweet Peas scarcely equalled those of previous years. Vegetables were staged in good condition. There were many good miscellaneous exhibits of a non-competitive nature.

The awards in the more important classes were as follow:—

The premier award for a group of plants arranged for effect, and occupying an area not exceeding 500 square feet, was won by Messrs. J. CYPHER & SONS, Cheltenham, with one of their usual meritorious exhibits put together in a most finished style.

The 1st prize for a similar smaller group not exceeding an area of 200 square feet, was secured by Mr. C. ROBERTS, Oswestry, with a light and graceful arrangement of Plants.

In a class for a group of Orchids in bloom, the plants were required to be arranged for effect, and were not to exceed an area of 100 square feet. The 1st prize was awarded Messrs. J. CYPHER & SONS, Cheltenham.

The best group of "Malmaison" and other Carnations was staged by Lord HENRY GROSVENOR, Tittenson Chace.

The best six plants in flower and six foliage plants were shown by Messrs. J. CYPHER & SONS, followed by Mr. W. VAUSE, and these exhibitors also won in this order in the classes for six plants in flower; for eight exotic Orchids; for six Palms; and for six foliage plants.

The largest class for Roses was for 72 blooms of distinct varieties. The 1st prize was taken by Messrs. A. DICKSON & SONS, Newtownards.

The KING'S ACRE COMPANY had 1st prize for 48 blooms of distinct varieties.

The prizes in the smaller class for 36 Roses in distinct varieties, three blooms of each variety, fell to the winners of the largest class.

Messrs. ALEX. DICKSON & SONS showed the best collection of 24 Hybrid Tea Roses, and they also had the best display of new Roses.

The best collection of hardy perennial flowers was shown by Messrs. HARKNESS & SONS, Bedale, and the best 12 varieties of Sweet Peas by Mr. A. G. HOLFORD, Ecclethall.

FRUIT AND VEGETABLES.

Fruit was largely and well shown, the decorated dessert tables and collections of fruit being of much merit.

Five displays were seen in the class for a decorated dessert table, that shown by Mr. N. F. Barnes (gr. to the Duke of WESTMINSTER, Eaton Hall) securing the highest (123) number of points.

In a class for twelve dishes of fruit, the schedule required not fewer than eight kinds and not more than two varieties of one kind; both black and white grapes were to be included, and flowers and foliage for decoration were allowed. Mr. J. H. GOODACRE was awarded the 1st prize; 2nd, J. DRAKE, Esq.

Mr. BARNES staged the best six dishes of fruit. Exhibitors in the previous class were restricted from entering in this.

Mr. GOODACRE won in the classes for four bunches of grapes, to include two bunches each of black and white varieties; for two bunches of Black Hambro', with fruits of fine colour; and for any other Black variety, with very good Muscat Hambro.

The best two bunches of Muscats of Alexandria were shown by Mr. J. MCPHERSON, while Mr. R. NISBET showed the best two bunches of any other White variety.

Mr. E. Beckett (gr. to Lord ALDENHAM, Aldenham House, Elstree) won the 1st prize for a collection of vegetables.

NON-COMPETITIVE EXHIBITS.

Messrs. BAKER, Wolverhampton, staged a fine exhibit of Roses, hardy flowers, &c. (Large Gold Medal.) Messrs. SUTTON & SONS, Reading, showed Melons, Gloxinias, Celsias, &c. (Gold Medal.) Mr. H. ECKFORD, Wem, displayed Sweet Peas. (Gold Medal.) Messrs. DOBBIE & Co., Rothesay, and Mr. C. E. WALTERS, Balcombe, were also awarded Gold Medals.

Silver Medals were awarded to Messrs. CLIBRAN, Altrincham; Messrs. JARMAN & Co., Chard; Messrs. HEATH & SONS, Cheltenham; Messrs. WEBB & SONS, Wordsley; and Messrs. PATTINSON, Shrewsbury.

ROYAL CALEDONIAN HORT. AND NATIONAL ROSE SOCIETIES.

JULY 18.—Half of the Waverley Market, Edinburgh, was set apart for this show, which was somewhat marred by the unfavourable weather. The Roses as a whole were not so large as might have been expected, and many of them bore marks of unfavourable weather. Sweet Peas had also suffered some damage from the same cause, but the show of these as a whole was a good one. Trade exhibits added greatly to the displays. There was a good attendance of visitors.

ROSES—OPEN CLASS.

The Jubilee Trophy for 36 blooms, distinct, was won by Messrs. A. DICKSON & SON, Newtownards, with fresh, well-coloured blooms, of which Mrs. W. J. Grant, Dean Hole, Mme. Crapelet, Mildred Grant, George Dickson (splendid crimson), Ellen Drew (lovely pink), Mrs. Sharman Crawford, Lady Ashton, and Souv. de P. Notting were the best examples; 2nd, Messrs. H. HARKNESS & Co., Hitchin.

The Class for 72 blooms, distinct, was also won by Messrs. DICKSON'S, with Messrs. HARKNESS again 2nd, Messrs. B. CANT & SON, Colchester, following. The blooms in each instance were less good than in Class 1. Messrs. DICKSON staged fine examples of Mrs. Myles Kennedy, Ulrich Brunner, Florence Pemberton, S. M. Rodocanachi, &c.

The best collection of 24 distinct varieties, three blooms of each, was shown by Messrs. B. CANT & SONS, with heavy, fresh, and well-coloured blooms, Papa Lambert, Frau Karl Druschki, Earl of Dufferin, Mildred Grant, Dean Hole, Madame Crapelet, Mme. Eug. Verdier, Ben Cant, Bessie Brown, and Alfred Colomb being the best. Messrs. A. DICKSON, Newtownards, were 2nd.

For 36 blooms, distinct, Mr. GEO. PRINCE, Oxford, won the 1st prize. Some of the blooms were well coloured, but most of them were of small size. 2nd, Messrs. J. JEFFRIES & SON, Cirencester.

Mr. PRINCE had the best collection of 16 varieties, three blooms each, with small, but fresh, blooms, Messrs. JEFFRIES & SON being 2nd.

The winner of the 1st prize for 18 distinct varieties (Tea and Noisettes) was Mr. PRINCE, with good White Maman Cochet, Medea, and Comtesse de Nadaillac. 2nd, Messrs. CANT & SONS.

Messrs. SIMPSON & SONS, Dundee, had the best collection of 12 blooms. 2nd, Messrs. JEFFRIES & SONS.

For 12 blooms of new varieties, Mr. HUGH DICKSON, Belfast, was 1st, with Mrs. Conway Jones, Richmond, Lady Ashton, Joseph Hill, H. Watson, Mrs. D. Niken, Princess M. Mertschersky, Mrs. Stewart Clarke, J. B. Clarke, and fine Lohengrin and Hugh Dickson. 2nd, Messrs. A. DICKSON & SONS.

The best dozen blooms of a white or yellow Rose were from Mr. PRINCE, who had rather small specimens of Maman Cochet; and the best Rose-coloured from Messrs. DICKSON'S, Edinburgh, who had Mrs. W. J. Grant; whilst the best crimson variety was J. B. Clarke, from Mr. DICKSON, Belfast.

In the class for the best 12 distinct varieties shown in vases Messrs. DICKSON & Co., Edinburgh, were 1st, with good Frau Karl Druschki, Caroline Testout, Captain Hayward, and Mrs. W. J. Grant. 2nd, Messrs. DICKSONS, Newtownards.

The competition for 18 varieties in a space of 8 feet by 3 feet was won by Mr. MATTOCK, Oxford, Messrs. PAUL & SONS being 2nd. Nothing in either exhibit was novel, though the latter firm showed Gottfried Keller, a semi-double of wondrous colour (copper and yellow).

The next class was for Roses arranged in bamboo stands, Mr. MATTOCK again winning the 1st prize, and Mr. GEO. PRINCE, Longworth, was 2nd.

There were classes for amateurs, in which the principal prizes were won by Messrs. F. DENNISON (Kenilworth), CONWAY JONES, Esq. (Gloucester), R. FOLEY HOBBS, Esq. (Worcester), the Rev. J. H. PEMBERTON, Mr. GEO. MOYLES, Mr. WHITTLE, Mr. E. MAWLEY (Sec. Nat. Rose Soc.), and Mr. E. B. LINDSELL.

Mr. Kidd, gr. to Lord ELPHINSTONE, Carbery Tower, had the best 16 vases of "Malmaison" Carnations; and the best collection of 12 bunches of Sweet Peas was shown by Mr. MALCOM, Duns. There was a good show of these sweet flowers. Mr. BRYDEN, Innerleithen, set up a grand lot of hardy flowers, for which the 1st prize was obtained.

FRUIT.

Displays of fruit were not numerous, Grapes being the most noteworthy feature. The best two bunches of Black Hamburgh were shown by Mr. BEISANT, Castle Huntly; 2nd, Mr. Stewart (gr. to Earl of LAUDERDALE), Thirlstane.

Mr. T. Young (gr. to Sir GEO. BULLOUGH), Isle of Rhum, was 1st for two bunches of white Grapes, with Muscat of Alexandria. Mr. YOUNG was also 1st for Nectarines, Mr. KIDD taking a similar place for Peaches. There were also classes for Strawberries, Melons, Figs, &c. A small display of vegetables was seen.

NON-COMPETITIVE EXHIBITS.

Messrs. DOBBIE & Co., Rothesay, set up an extensive array of cut flowers. (Silver Medal.)

Mr. FORBES, Buccleuch Nurseries, Hawick, staged a grand lot of herbaceous flowers. (Silver Medal.)

Messrs. J. GRIEVE & SON, Pilrig, Edinburgh, had a bright display of Violas. (Silver Medal.)

A delightful exhibit of pillar Roses was shown by Messrs SIMPSON & SONS, Dundee.

Messrs. STORRIE & STORRIE, Dundee, furnished a large table with fruiting Apple trees in pots, also Currants and Gooseberries. The same firm displayed Poppies, Sweet Peas, and Begonias. (Gold Medal.)

A charming exhibit of herbaceous flowers in great variety was staged by Messrs. JAMES COCKER & SONS, Aberdeen.

Messrs. GUNN & SONS, Olton, Birmingham, showed garden Phloxes. (Silver Medal.)

Messrs. CUNNINGHAME, FRASER & Co., Comely Bank, staged Alpine plants and herbaceous cut flowers. (Silver-Gilt Medal.)

Messrs. LAING & MATHER, Kelso, showed Carnations in variety. (Silver Medal.)

Mr. A. PERRY, Winchmore Hill, had Water Lilies in variety and vases of Richardia Elliottiana, and R. "Mrs. Roosevelt." (Silver Medal.)

Messrs. CAMPBELL & SON, High Blantyre, exhibited Pinks and Carnations and Cactus Dahlias. (Bronze Medal.)

MARKETS.

COVENT GARDEN, *July 18.*

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday, by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate, not only from day to day, but occasionally several times in one day.—ED.]

— bags	1 0	—
Turnip Tops, bush.	1 0	1 6
Watercress, per doz. bunches	0 6	—

REMARKS.—English Tomatos are cheaper. Prices for Peaches and Nectarines are firmer, and good, large, well-coloured fruits are in demand. Raspberries are inclined to be a little dearer, especially those for jam making. The vegetable and fruit trade generally is quiet. *A. H. Kitt, Covent Garden, July 18, 1906.*

POTATOS.

Lincolns, 80s. to 90s.; Bedfords, 70s. to 80s.; Kents, 80s. to 100s.; Jerseys, 100s.; St. Malo, 90s. *John Bath, 32 and 34, Wellington Street, Covent Garden.*

COVENT GARDEN FLOWER MARKET.

The market now presents a rather deserted appearance most of the stands in the new portion were quite empty this morning. Some of the growers, however, continue to fill their stalls with good material. Mr. W. T. Child has good Zonal and Ivy-leaved Pelargoniums; Mr. Shoult has good Pelargoniums, &c.; Mr. Sweet is displaying Marguerites, Verbenas, &c.; Mr. T. Childs has very good Hydrangeas, Campanula Mayi, and useful Ferns; Mr. E. Rochford has good Crassulas, Liliums, Hydrangeas, &c.; Messrs. Ward Brothers are bringing good Marguerites, Fuchsias and Heliotropes; Mr. Mott has Mignonette, Pelargoniums, Fuchsias, &c.; Messrs. H. Evans & Sons have very good Coleus, Ferns, &c.; Messrs. J. Hill & Son's stands are well filled with Ferns, including many of the choicer sorts; Zonal Pelargoniums from Mr. T. Larsen are good; Messrs. Fuller Bros. have good Chrysanthemum segetum, Fuchsias, Marguerites, &c. On Mr. Hutching's stands I noted good Chrysanthemum (Marguerite) Queen Alexandra. Mr. H. Cull is still bringing in good Zonal Pelargoniums. Mr. H. B. May continues to fill his stands with a variety of useful plants, including Kochia scoparia, which is also coming from Mr. Thompson's nurseries, whom, I am told, received it from the Continent under the name of Kochia trichophila, that grown under the name of K. scoparia having proved of no use for market work. As other growers may procure the wrong plant, this is a matter which should be noted. Messrs. H. Low & Co. have their stands well filled with Palms of various sizes. Mr. R. Brost, Mr. Bause and Mr. Durrard also continue to send Palms. Lily of the Valley and Rose Madame Levavasseur, from Messrs. T. Rochford & Sons, are both good.

CUT FLOWERS.

Trade now varies considerably, and choice flowers are not so plentiful as formerly, although quite equal to all ordinary demands. Growers soon ascertain when there is an extra demand, and put up prices correspondingly. On two occasions recently, Liliums have quickly advanced in prices, but the increase was only temporary. Far too many Roses from the open ground are seen, but the very best quality blooms are not so plentiful. The same may be said of Carnations, of which too many of second quality are seen. I find "Malmaisons" are rather low in prices except for extra special blooms. American varieties are still good. Chinese Asters are hardly of first quality; pink and the white are the only colours I have seen up to the present. Centaurea suaveolens, the ordinary yellow sweet Sultan, is very nice; the white and the mauve varieties are also seen. Sweet Peas, supplies of which fell off a little, are now over plentiful again. Gaillardias, Coreopsis, Delphiniums, Malvas, and other hardy flowers arrive from all parts of the country. Scabiosa caucasica is very pretty, also Statice latifolia in white, yellow and blue varieties. Liliums are fairly plentiful again. L. candidum from the open brings down the prices of L. longiflorum. Chrysanthemums from Mr. P. Ladds are still remarkably good, also Iceland Poppies from Mr. J. Lowe. At closing time this morning much useful material was unsold. Growers complain of bad trade, but I think the chief fault is that supplies are over abundant. *A. H., Covent Garden Market, July 18.*

SCHEDULE RECEIVED.

NATIONAL CARNATION AND PICOTEE SOCIETY'S (Southern Section) twenty-ninth annual report, and schedule of prizes for their exhibition on Tuesday, July 24, 1906, in the Royal Horticultural Hall, Westminster.

POLITICAL GARDENERS.—At Watford on Monday last the hearing was resumed of the charge against EDWIN LAYTON under the Corrupt Practices Act, it being alleged that he dismissed a gardener for voting on the Liberal side at the last election. Mr. GRAHAM-CAMPBELL prosecuted for the Treasury, and Mr. BODKIN defended. MONTAGUE, the head gardener, recalled, admitted that Mr LAYTON said that he did not wish to be hard, and if the three gardeners had not anything to do they need not hurry away. HERBERT JOHN WINTERS, the under gardener, said that he asked his master if they were dismissed because of their political views, and he said "Yes." *Daily Graphic.*

Obituary.

BENJAMIN MARKS.—The death occurred recently of Mr. Marks, who for the last 15 years has been head gardener to Guy Milner-Gibson Cullum, Esq., Hardwick, Bury St. Edmunds, and formerly head gardener to C. R. Palmer-Morewood, Esq., of Altreton Park, Derbyshire.

ENQUIRIES AND REPLIES.

LATHYRUS NERVOSUS.—Can anyone tell me where I can obtain seeds or plants (preferably seeds) of Lathyrus nervosus? *L. A. D.*

ANSWERS TO CORRESPONDENTS.

ASTERS DISEASED. *J. P. H.* The plants are attacked with a fungoid disease, Erysiphe Cichoracearum. The plant and soil should be sprayed every five days, until the disease is checked, with a solution of permanganate of potash (Condy's Fluid), diluted with water to a pale rose colour.

BEECH COCCUS.—*C. Bliss & Co.* If labour can be spared for the purpose the best manner of clearing the trees of this pest is to scrub the bark and its crevices with caustic soda wash or with petroleum emulsion. The trees can be

sprayed in the autumn with either of these insecticides, but the scrubbing brush is the best remedy. This is quite practicable as the Coccus only attacks the main trunk and the larger branches.

Black Muscat: *F. B. P.* This excellent Grape is in general cultivation, its name being Muscat Hamburgh. It is sometimes described as the Black Muscat of Alexandria. There are other varieties regarded as Black Muscat Grapes, such as Mrs. Prince, Madresfield Court, Meurthe Frontignan, &c. Muscat Hamburgh is reddish rather than black.

Cercospora Melonis: *W. C. B.* This disease of Melons and Cucumbers was first described in the *Gardeners' Chronicle*, September 5, 1896, p. 271, by Dr. M. C. Cooke, and a very full account was also given on p. 241 in our issue for October 4, 1902, in which a spraying with potassium sulphide, 2 ozs. to 3 gallons of water, adding 2 ozs. of soft soap, was recommended as a cure. It is important that the under surface of the leaves be thoroughly wetted with the solution. The soil should also be drenched with the dissolved potassium salt. Diseased leaves should be removed and burned before they decay and fall to the ground. If possible do not grow Melons or Cucumbers in the same house for a season or two. Carbolic acid stood about the house in jars has been known to do much good in checking this disease.

Cotoneaster: *J. M.* This genus is not, so far as we know, poisonous to cattle. The plants contain tannin, but no virulent poison.

Cucumber: *C. B.* Your plants are affected with a fungus. Burn the diseased plants.

Cycas revoluta: *F. S.* It is not uncommon for this stove plant to produce male cones in this country.

Fruit, Flower and Vegetable Trades' Journal: *A. W. S.* The address is 139, Salisbury Court, Fleet Street, London.

Grape Spot: *F. L.* Your berries are affected with spot, so often described in our columns—see last week's issue, p. 40.

Green Peas and French Beans. *W. J. M., Isleworth.* To bottle, shell the Peas and put them into wide-mouthed bottles. The Beans are better wiped dry and put into the bottles whole. Shake them together so that they may lie as closely together as possible. Cork the bottles well and seal the corks. Bury the bottles in the driest part of the garden, and take them up as they are wanted. They should keep good for five or six months.

Insecticides: *J. P.* Apply to Messrs. Strawson's, 71A, Queen Victoria Street, London, E.C.

Names of Plants: *J. L.* Pithecoctenium cynanchoides, D C. A native of Brazil.—*H. G. P.* 1, Magnolia acuminata; 2, Rubus odoratus; 3, Berberis vulgaris; 4, Gaultheria Shallon; 5, Andromeda calyculata; 6, Euonymus latifolius.—*B. M. S.* Spiræa chamædrifolia.—*Trehane.* 1, Pyrethrum corymbosum; 2, Orchis latifolia, a very fine form; 3, Erigeron philadelphicus.—*R. H. W.* 1, Euphorbia chamæcyparissus, 2, Dianthus cæsius; 3, not recognised.—*T. O.* 1, Thuya dolabrata; 2, Tsuga Pattoniana; 3, Juniperus virginiana; 4, Tsuga canadensis; 5, Abies orientalis, 6, Thuya filifera.—*R. M.* Phillyrea augustifolia.—*L. H.* 1, Chrysanthemum segetum; 2, Galega, sp. not recognised; 3, Orchis maculata. 4, Philadelphus coronarius; 5, Oxalis Bowiei.—*W. H. D.* Seed pod, probably of some Gleditschia, of no use to the cook. The Mint-like plant is Mentha Requieni.—*F. S.* Seedling, probably of some composite. Send when further advanced.—*Nemo.* 1, Spiræa Ulmaria; 2, Spiræa Filipendula; 3, Allium Moly; 4, Scabiosa caucasica; 5, Phlomis fruticosa; 6, Hemerocallis fulva; 7, Inula glandulosa; 8, not recognised.—*A. Y. L.* The greenish flower is Lycaste Barringtoniæ; 2, Sarcanthus, probably Williamsoni. The Cypripedium Stonei is a very good variety.—*W. I., Belfast.* 1, Oncidium flexuosum; 2, Oncidium obryzatum, 3, Oncidium luridum; 4, Odontoglossum Hunnewellianum; 5, Sophronitis cernua; 6, Ada aurantiaca. *Berks.* Oncidium leucochilum and Adiantum Waltoni. *V. E. I.* 1, Selaginella helvetica; 2, Selaginella umbrosa, 3, Selaginella lævigata.—*A. G.* Alstrœmeria Pelegrina; 2, Centranthus ruber; 3, Galega officinalis; 4, Hemerocallis fulva.—*M. A.* 1, Lilium superbum, 2, Dictamnus Fraxinella. *A. J. K.* 1, Sidalcea malvæflora; 2, Campanula species; 3, Senebiera coronopus.—*W. K., Droitwich.* 1, Sedum Ewersi; 2, Alchemilla vulgaris; 3, Sedum spurium; 4, Spiræa Filipendula; 5, Sedum album; 6, Heuchera sanguinea.—*C. A. B.* Rubus odoratus.—*W. B. R.* Polygonum Baldshuanicum.—*H. C.* 1, Colutea arborescens; 2, Eccremocarpus scaber; 3, Centranthus ruber.—*G. L.* 1, A species of Ononis, send when in flower; 2, Spiræa Douglasi; 3, Spiræa salicifolia; 4, Lychnis Haageana, 5, Epimedium, send when in flower; 6, Tiarella cordifolia.—*R. R.* 1, Eucomis punctata; 2, Fuchsia procumbens; 3, Cystopteris fragilis; 4, Polypodium Dryopteris; 5, Asplenium bulbiferum; 6, Oreodaphne californica.—*M. R. M.* Odontoglossum Lindleyanum.—*T. R.* 1, Dabeocia polifolia alba; 2, Santolina incana; 3, Veronica Traversi; 4, Spiræa Bumalda; 5, Agrostemma coronaria alba; 6, Centranthus ruber; 7, Escallonia macrantha.—*W. J. W.* Pavia lutea, sometimes called Aesculus.—*A. L. F.* 1, Campanula, probably C. Rapunculus; 2, Chrysanthemum maximum; 3, Aster alpinus; 4, Hieracium aurantiacum; 5, not recognised; 6, Verbascum species.

"New" Potatos at Christmas: *T. T.* The following method is described by a correspondent as having answered admirably. First of all dig a hole 3 feet in depth, and procure some biscuit tins about 9 inches long and 4 inches wide, having close-fitting lids. Tubers of a kidney-shaped Potato having a smooth skin should be selected for storing. Snowdrop is a suitable variety, and as each root of Potato is dug pick up the tubers and put them in a basket, which should be immediately covered with haulm or anything to prevent the tubers from drying. When sufficient has been dug, take them to a shed and pack them thickly into the biscuit tins. No soil or any material is put with them. The tins should then be buried in the hole prepared for them, and a stick put in the ground to denote their whereabouts. It is best to select medium sized tubers, just such tubers as are generally described as "new" Potatos. Remember that it is necessary to dig and store the tubers away in the tins before the skins are set, or they won't keep well, nor afterwards scrape like "new" Potatos. A little green or dried Mint should be boiled with the tubers. If properly stored in the manner indicated, they are quite equal when cooked at Christmas or early in spring to those new Potatos sent from the Jersey and Guernsey islands in the early spring.

Onions Diseased: *C. H. T.* The plants are affected with the Onion mildew, Peronospora Schleideni. In the early stages of the disease it may be checked by dusting with powdered lime and sulphur, using twice as much lime as sulphur. Spraying with potassium sulphide ½ oz. to a gallon of water—is also recommended. Onions should not be grown on the same spot of land for three years, by which time all the spores in the soil will have perished. Damp and shaded situations favour the spread of the disease.

Peas: *H. G.* Pea mildew. You can do nothing practical now but burn the affected plants; next season you might spray with some weak fungicide while the plants are young.

Pelargoniums: *H. C.* The coloration is probably due to drought or dry conditions. It is not to be despised. *Rockum.* The cuttings have been planted too deeply and have probably been over-watered—conditions which favour the development of the fungus.

Plants Dying: *H. C.* Without knowing more of the circumstances we cannot give a definite opinion. We find neither insect nor fungus—and agree with you that the case is a suspicious one.

Soil: *J. S.* We are unable to assist you unless we could tell what the fungus is.

Sphagnum-Moss. *A. v. d. G.* We do not know what worms you mean. Kindly send specimens with a little of the Moss also, packed separately.

Sport: *Evelyn.* The term "sport" may be applied to any variation arising from buds, but is also loosely applied to variation from seeds. Reversion to a previous type would be more correctly described as "atavism" than a sport, but it is a sport or variation nevertheless, and is frequently described as being a sport because it is not always known at the time that the variation is identical with a form which existed previously. In gardens the term "sport" is generally held to describe a variation arising from the bud. Bud variations are "sportive," but the exact reasons for such variations are not apparent, though they may generally be cases of atavism, or in other instances they may be due to the separation of previously blended characteristics. Variations resulting from sexual action should not be termed "sports." The word is not a strictly scientific term, and, therefore, it is used somewhat loosely.

Strawberries: *B. H.* The variety Royal Sovereign is the most commonly grown Strawberry in this country, but its flavour is inferior to that of some older varieties, including Sir Joseph Paxton which is less acid.

Strawberry Grubs: *J. R. K.* What you send are weevil grubs. Trap them with slices of Carrot or Potato.

The "Double" White Lily: *W. E.* In this form no true flowers are formed, but a series of white bracts. It is a very old form and is mentioned in the old herbals, we think in Parkinson & Gerard.

To Make Pot Pourri: *F. A. W.* This is but little used now, but here is an old-fashioned recipe for it which may interest you. Put into a large china jar the following ingredients in layers, with bay salt strewed between the layers: Two pecks of damask Roses, part in bud and part bloom; Violets; Orange flowers and Jasmine a handful of each; Orris root sliced; Benjamin and Storax, 2 ounces of each; a ¼ ounce Musk; a ¼ lb. Angelica root sliced; a quart of the red parts of Clove Gillyflowers; two handfuls of Lavender flowers; half a handful of Rosemary flowers; Bay and Laurel leaves, half a handful of each; three Seville Oranges stuck as full of Cloves as possible, dried in a cool oven and pounded; half a handful of knotted Marjoram, and two handfuls of Balm of Gilead, dried; cover all quite close. When the pot is uncovered the perfume is very fine. Here is a simpler recipe, which is more to your purpose: three handfuls of Rose petals; three of Orange flowers; three of Clove Pinks; one of knotted Marjoram; one of Lemon Thyme: six Bay leaves; a handful of Rosemary; one of Myrtle; half a one of Mint; one of Lavender; the rind of a Lemon and a ¼ ounce of Cloves. Chop all, put the ingredients in layers with pounded bay salt between them up to the top of the jar. If all the ingredients cannot be obtained at once, put them into the jar as you get them, always throwing in salt with every new article.

Tomato Spot: *R. B.* See answer to *R. F.*, in our last issue, p. 40.

Tomatos: *W. B.* We know of no better market variety than Lister's Prolific if obtained true. Carter's Sunrise is also a capital sort for the same purpose. Such a book as you enquire for is *Tomato Culture for Amateurs*, by B. C. Ravenscroft, to be obtained from our publishing department, price 1s. 1d. post free.

To Preserve Lemon Juice: *Querist.* It is a very difficult matter to preserve Lemon juice without the admixture of spirit. It would be necessary, as you wish it to keep for months, to mix a small quantity of borax or salicylic acid with the juice. Your chemist would tell you the proper quantity, but I do not think, from personal experience, that you would care for the mixture. Lemon juice is most valuable when it is used from fresh Lemons. The aromatic flavour of the Lemon is chiefly in the rind close to the surface of the Lemon, not in the white part. Any Lemon-squeezer will do to express the juice; preferably use a glass one, as metal is apt to impart an unpleasant flavour to the juice. *E. M.*

A RIVERSIDE PARADISE.

IT lies on a curve of the river between Shepperton and Chertsey—a modest villa washed by Thames, as the villa of Horace's friend Dellius was washed by yellow Tiber; standing on some ten acres of land, consisting of ancient islands, with a river frontage of about 800 yards. The approach is only from the Thames, communication with the outer world being maintained by the means of a jolly young waterman with an ever-present punt. This ferries visitors to a narrow landing between bushes of fragrant mock-orange, whence steps lead up to a pretty two-storied, verandah-bordered house, bearing on its front a felicitous motto from Tibullus:—

Jam modo iners possim contentus vivere parvo,
Nec semper longæ deditus esse viæ:
Sed Canis æstivos ortus vitare sub umbra
Arboris, ad rivos prætereuntis aquæ.

which, being interpreted, becomes

Here, fancy free, and scorning needless show,
Let me from Life's dull round awhile retreat,
Lulled by the full-charged stream's unceasing flow,
Screened by tall willows from the dogstar's heat.

A little way off is a second, smaller house, bearing a legend, less classical, but not less apt:—

Parva, sed apta mihi, sed nulli obnoxia, sed non
Sordida, parta meo sed tamen ære, domus.

It will run thus in English:

'Tis tiny, but it suits me quite,
Invades no jealous neighbour's right,
'Tis neat and clean, and—pleasant thought—
I earned the cash with which 'twas bought.

The two houses stand in an open space, which supplies room also for a well-equipped boat-house, and a couple of lawn-tennis grounds, interspersed with lush meadow grasses, Foxtail, Cocksfoot, Holcus, Arrhenatherum, and tall Poa. The concrete paths are bordered with garden annuals, Tropæolums, Poppies, Clarkias, Eschscholtzias—those punctual chronometers, which, whether in cloud or sunshine, just now open before 9 a.m. and close at 4 p.m. There is a profusion of the brilliant little Eutoca, of its kinsfolk the Nemophilas, of the strange-looking Phacelia, of the large pink Malope, of orange Cheiranthus, blue Centaury, Limnanthes (beloved of bees), Linarias and Candytufts', with, here and there, dwarfing its neighbours, the Virgin Mary's Thistle. Sown early, these illuminate the border through the summer season, and are not cast into the oven until the retreat is deserted and the house shut up in autumn.

This open space is surrounded on all sides by thickly-planted Willows, whose fleecy seeds fill the air in June like snowflakes or white butterflies; they are lined with Philadelphus grandiflorus, and amongst them are Hawthorns, black and Lombardy Poplars, and low trees of Rhamnus catharticus. Roughly kept paths of 7 feet wide are cut through their entire length, revealing a varied and interesting riparian wild Flora. The common Nettle (Urtica dioica), usually a repellent plant, here rises to a height of 7 or 8 feet; its inflorescence stunted or effaced by the deep shade, its leaves and stems of unwonted size and richness. Amongst it here and there grow plantations of feathery Digraphis arundinacea, with Comfrey, white, blue, and sometimes crimson. By these only the thickest Willow growth is peopled: so soon as the trees become less crowded and admit more light, we have luxuriant masses of Valerian (V. officinalis), mixed with Meadowsweet and Thalictrum flavum; occasional clumps of yellow Iris warning thinly-shod ladies against patches of swampy ground. Heracleum giganteum, by some accident introduced, towers high where it can get a chance; on it, or on pendent boughs, climbs the large Bindweed, with its pure white trumpet-shaped blooms and frail pointed leaves. The purple Bittersweet, confused popularly with the very different Deadly Nightshade, twines here and there among the Hawthorns. The paths are carpeted with ground Ivy and the delicate Wood Pimpernel; show occasional wild raspberry, and currant, black and red: Angelica promises autumnal bloom, and Rape, washed in by floods, sprinkles its yellow flowers everywhere. The disagreeable weed of the plantations is the Cleavers, Galium Aparine; it grapples and tears down all tender plants, covers the ground with strangled heaps, and withers soon into an ugly yellow decay. Only in the spring can it be eradicated, not without great labour, which would not, however, be wasted in this lovely wilderness.

Beyond the demesne on the land side is Chertsey Mead, a level meadow of vast extent, stretching away towards St. Ann's Hill, the home during his later years of Charles James Fox. But the Willow Grove is islanded by a backwater or eddy of the Thames, wide at first, then continued into a narrow ditch. The eddy exhibits on both sides the typical Thames flora. On its still waters float Water Lilies, white and yellow, and the lovely fringed bog-bean Villarsia (Limnanthemum) nymphæoides; on its bank stands up the Sweet Rush (Acorus calamus), with its wrinkled, fragrant leaves and long stiff flowering spathe, the Sparganium, the Flowering Rush (Butomus umbellatus), known here as "Pride of the Thames," Water Parsnip, Marshgold still in fruit, Bidens cernua, Sneezewort (Achillæa ptarmica), blue Forget-me-not, Marsh Ragwort, Gipsywort, and Mint. There is the so-called red Loosestrife (Lythrum Salicaria) side by side with Willow herb, the Codlins and Cream of our Childhood, and bushes of the true yellow Loosestrife, its English name a clumsy adaptation of the Greek Lysimachia, though what the General Lysimachus had to do with it no one seems to know. On the shallow edges are Water Plantain, Arrowhead, square-stalked St. John's Wort; just above, the water round-headed Garlic, established somehow in this unlikely place, the bright blue Skull-cap, Marsh Wound Wort (Stachys palustris), Nasturtium palustre, own brother to Water Cress, Fig Wort, on whose pretty blooms wasps will be swarming by and by, the two fine Carices, riparia and pendula, with the red inflorescence and magnificent leaves of Rumex hydrolapathum. A curious American plant, the Orange Balsam (Impatiens fulva), imported somehow into the banks of the Wey, and profuse on these banks ten years ago, is now all but extinct, in consequence of the great summer flood of 1903. The continuing ditch is fenced by nettles, unattractive in the open, but deterrent to invading trippers; amongst and underneath them, neighboured by baser quality, like the Bishop of Ely's strawberry in Shakspeare, straggle in cerulean profusion masses of the lovely Geranium sylvaticum.

If the Retreat is a Paradise for mortals, it is no less an aviary for birds. Pigeons and doves croon and coo from the tree-tops; we have

Blackbird and thrush in every bush,
Stare, linnet, and cock sparrow,

as in Elizabethan Heywood's pretty song; sedge-warbler, willow-warbler, reed-warbler, wood-warbler, blackcap, nest and sing and chatter in the willows, the grasshopper warbler trills, cricket-like, out of sight, wagtails haunt the landing place, and the flycatcher poises for his excursions on the eaves. They rouse one another in earliest morning, before the thrush and blackbird; then the awakened sleeper through his opened window enjoys their soft orchestra, distinguishing with trained ear the hurried twitter, or the plaintive mellow repetition, or the continued roundelay, or the defiant chiding, or the garrulous, grating remonstrance of each tiny songster. To the close growth of the foliage round them is due, no doubt, their immunity from the enemies who share their home: the sparrow hawk, the white, tawny, long-eared, and short-eared owl, and, most dangerous of all, the silent creeping stoat. Of other larger birds we have the spotted, but not the green woodpecker; the landrail croaks confidentially from the meadow, and to our annual kingfisher's nest a second has this year been added. Such cuckoo vocalisation, while June lasted, I never heard. It began at 2.30 a.m. and continued till after dark. It gave us all the strains in its repertory; the cuc-cuc-cuc-koo, the very unusual cuc-koo-koo, the descending interval in the

minor third, the soft love note cule-cule, the cackle, the harsh chatter. An American lady was in the house when the chant was at its height. She thought at first it was a cuckoo clock, that being the only form in which Wordsworth's "wandering voice" was known to her: for the American cuckoo, though domestically minded, unlike our profligate rover, is voiceless. We were able to show her the phenomenon of a cuckoo foundling; an egg rather larger than, but closely allied in marking to, the four legitimate eggs in a sedge-warbler's nest. It was soon afterwards hatched: the native eggs disappeared; the supplanter grew into a great sprawling mass of feathers, opening a cavernous orange-coloured mouth and snapping viciously at any approaching finger; the poor foster parents feeding it unwearicdly. It is still, in mid-July, conducting itself with hereditary irregularity, but must in a few days quit the nest.

From wild birds to tame is an easy transition; and I must not overlook a pair of stately swans, the gentleman and lady pensioners of our river side, who daily rely upon the inmates for food. Six eggs were hatched in June, but three chicks fell a prey to rats, and the survivors swim after the parents now, the old birds refraining from the food thrown out until the young appetites are satisfied.

I might draw lessons from virtuous swans and vicious cuckoos; from aspiring bindweed and clinging hop; from punctual Eschscholtzia, converted Nettle, encroaching, short-lived Cleavers. But I remember how, when I was a boy, I carefully erased the officious "L'Envoy" from every fable in my Æsop; and I simply photograph our Paradise, leaving those to point its moral, who prefer a parable to an idyll. *Corycius Senex.*

HOODIA CURRORI.

Kew is indebted to Mr. J. Gossweiler, of Portuguese West Africa, for two good plants of this remarkable Stapelia-like plant, which he forwarded two years ago. He found them growing "in scoriaceous matter of granite rocks at Leangue, twenty miles from the coast of Benguella." They were subjected to dry or succulent treatment at Kew. But this treatment did not suit them, and so one was tried in a hot moist house along with Caladiums. Here it plumped up quickly, rooted, and in a few weeks started into growth and flowered perfectly. The second plant has done equally well under the same treatment, and is in flower now (July 21). The moral of this is obvious. The Hoodias, of which four species are known, may be called thick stemmed Stapelias: indeed, Mr. N. E. Brown, in a masterly revision of Stapeliæ, published in Hooker's *Icones Plantarum*, Vol. X (1890), says there is very little in any of their botanical characters to justify keeping them apart from Stapelias. H. Currori is the third species to flower at Kew. The first was H. Gordoni, sent to Kew in 1874 by Sir Henry Barkly, then Governor of the Cape. It forms a cluster of erect succulent stems covered with rows of spine-tipped tubercles, and bears yellow flowers 4 inches across, suggestive of a big Œnothera, but of course much more fleshy. It is not now in cultivation, but there is a good figure of it in the *Botanical Magazine*, t. 6,228, and a photo-illustration in *Gardeners' Chronicle*, 1873, p. 576.

H. Bainii was introduced from Beaufort West in 1876, where it was found by the traveller, Thomas Bain. It flowered at Kew in 1877, and a figure of it was published in the *Botanical Magazine*, t. 6,348. It has yellow, purple-tinted flowers, somewhat smaller than H. Gordoni and more cup-shaped.

H. Currori was discovered in 1879 by Dr. Curror, of H.M.S. Water-Witch, in barren, sandy mountains at Elephant's Bay, West Africa, but it has not been known in cultivation before the present time. The plant in flower now at Kew has a stem 2¼ inches in diameter, 12 inches high (they are said to grow to a height of 2 feet), with 12 longitudinal ridges, each formed of some 30 or so confluent spine-tipped mammæ. The flowers are 5 inches in diameter, saucer-shaped, the inside surface covered with soft hairs and coloured dull rosy-lilac with darker radiating lines: the outer surface is glabrous and paler. The flowers last at least a month, and in addition to their size and other attractions they have the very excellent quality of being non-odoriferous, in which respect they differ very much from the Stapelias proper.

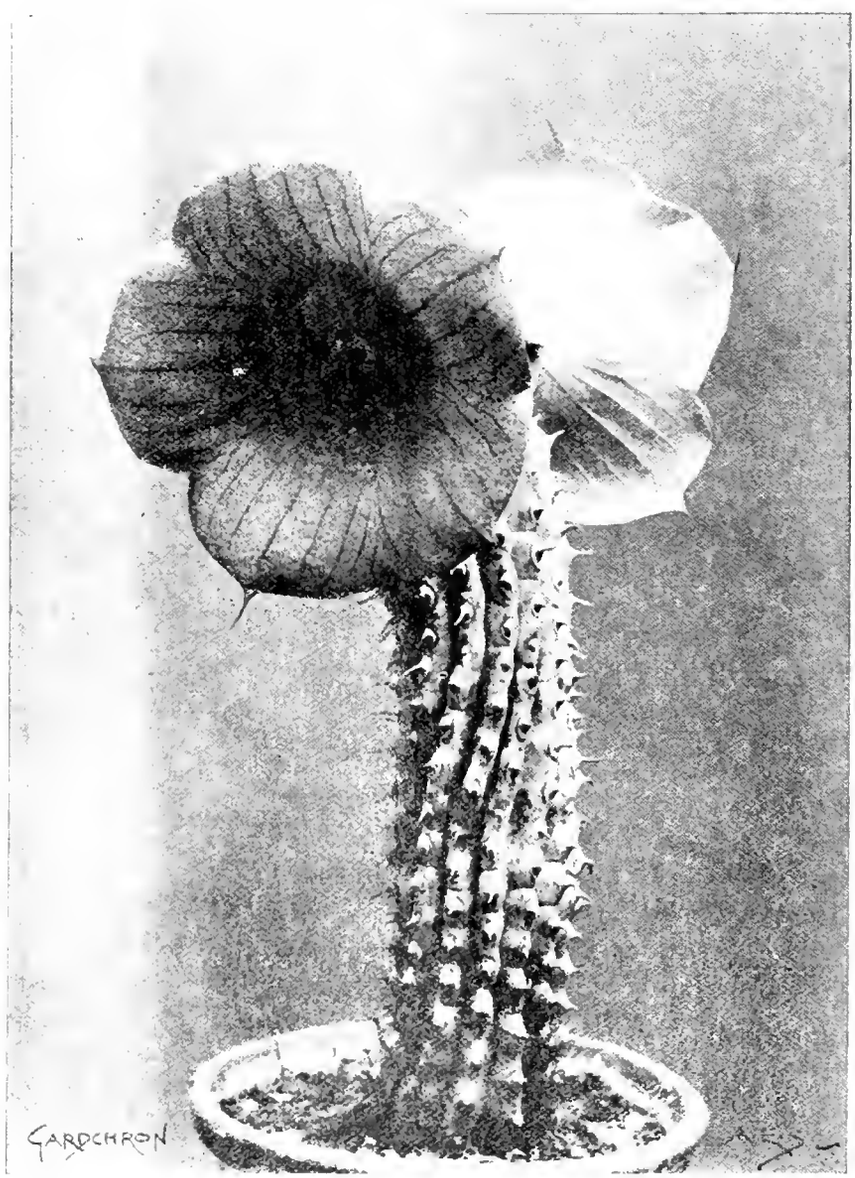

FIG. 27.—HOODIA CURRORI, FLOWERING FOR FIRST TIME AT KEW IN JUNE LAST. FLOWERS YELLOW FLUSHED WITH ROSE, REDUCED ABOUT ONE-HALF.

The Week's Work.

PLANTS UNDER GLASS.

By B. Cromwell, Gardener to T. Sutton Timmis, Esq., Clevelcy, Allerton, Liverpool.

Pelargoniums that, having flowered early, have been cut back, will now be growing freely, and should be shaken out of their pots, repotted into smaller ones, and placed in a cold frame, keeping the frame somewhat closed for a few days afterwards. Any plants which have flowered later should be exposed to the influences of the sun and air, and be kept drier at the roots, by which treatment the wood will become thoroughly matured previous to the plants being cut back. Where it is desirable to increase the stock, a few cuttings may be rooted singly in small pots, selecting for this purpose short-jointed and partly-matured wood, which will root freely.

Calceolarias.—When the seedlings are large enough, carefully prick them off into small pots, and place them in a frame having a north aspect, keeping the frame closed for a few days. Very careful watering at this stage is necessary, otherwise the young plants will become diseased at the roots. If the sittings of charcoal are used in the potting compost there will be less danger of the plants "going off" in a young state. Fumigate the plants regularly but very moderately.

Fuchsias.—Afford liquid manure to plants which are now flowering freely. Remove the old flowers regularly before they form seed. A few more cuttings may now be propagated, and, when they have rooted, shift them on into 60-size pots. If these are kept growing gently through the winter, they will make useful plants for flowering early next season.

Begonias, as they get past their best, should be encouraged to grow for some little time longer, after which gradually reduce the supply of water at the roots previous to their going to rest.

General Remarks.—The present time affords an opportunity to thoroughly overhaul, clean, and paint, if necessary, the interior of houses, also pits and frame from which the general stock of plants has been removed for a short time outside. If work of this kind is taken in hand at

once, the structures will be ready to receive the plants when the time arrives for housing them. Insert cuttings of Ixoras, Stephanotis, Dipladenias, Allamandas, Dracænas, Crotons, and Pandanus, selecting short-jointed, half-ripened wood for this purpose.

FRUITS UNDER GLASS.

By T. W. BIRKINSHAW, Gardener to Lt.-Col. Sir CHAS. HAMILTON, Bart., Hatley Park, Bedfordshire.

Plum trees in pots.—All the fruit having been gathered from early varieties, the trees should now be plunged out of doors, affording them good soakings of water and an occasional dose of diluted liquid manure. When these early varieties have been taken outside, the later ones may be given more room in the houses, and they should, if possible, be staged by themselves. Continue to keep the shoots pinched back, and to afford liberal stimulants to the roots. The syringe should be applied frequently, using clear water as free from lime as possible, in order not to leave any marks on the fruit.

Melons in frames will be swelling their fruits rapidly, and should be given all the encouragement possible by giving them abundance of water and applications of weak liquid manure twice a week until they are on the point of ripening. Remove all surplus growths as they appear, and fix the fruits in such a position that they will be exposed to the light and sun; inverted flower pots will do very well for this purpose. Plants that will fruit in succession to those growing in frames, and are now in the flowering stage, may be kept a little drier, both at the roots and as regards atmosphere. Larger fruits are not so much appreciated as those which weigh two or three pounds each, for once a Melon has been cut into it will not retain its full flavour until the next day. Plants that have small fruits in the stage of their first swelling will be greatly benefited by giving them a top-dressing of loam and a little bone-meal added. Syringe the plants, and close the frames early on bright afternoons.

Strawberries.—The earliest batch of runners for next season's fruiting under glass should now be ready for transferring into their fruiting pots. The most suitable compost for them is one of good turfy loam, with a little manure from an old Mushroom bed which has been passed through a three-quarter-inch riddle, adding a sprinkling of bone-meal and soot, and thoroughly mixing all these ingredients together. Let the plants be thoroughly well watered before turning them out of the small pots, and the fresh pots be cleansed if they have been used previously. Place about 1 inch deep of crocks in the bottom of each pot, and then a sprinkling of half-inch bones over the crocks, but these bones must be old and perfectly dry, to prevent the introduction of maggots into the soil. After potting they should be placed on the north side for about ten days, and be sprinkled overhead each evening with a fine-rose can. Afterwards arrange the plants in an open quarter in the kitchen garden where they will be exposed to full sunshine. They should be stood on a hard base of ashes or boards which will prevent worms from getting into the pots. Remove all runners as they appear. Later layers of runners should now be cut from the old plants and treated similarly. To obtain success in the forcing of Strawberries it is necessary to get the plants into the final pots as early as possible.

THE FLOWER GARDEN.

By HUGH A. PETTIGREW, Gardener to the Earl of PLYMOUTH, St. Fagan's Castle, Glamorganshire.

The Perennial (Herbaceous) Lobelia.—Lobelia fulgens and L. cardinalis and their varieties are indispensable for the ornamentation of the flower garden, and are worthy of being grown in large numbers, because of the brilliancy of their rich crimson flowers in late summer and autumn, and for their stately and erect habit of growth. They are well adapted for use in all phases of gardening. In the formal system these Lobelias are invaluable for ribbon-borders, or in making bold centres for beds or designs, where their coloured foliage and flaring flowers become singularly appropriate. Again, in the mixed borders, if arranged in groups in congenial companionship with other flower colours, they yield a gorgeous display, the effect of which lasts long into the autumn. But perhaps the best effect is obtained by their use as an adjunct in connection with water gardening. In the wild garden fringing the sides of the stream, or in masses planted in the shallow margin of a pond, backed by Japanese Irises and other water-loving plants, they create a sheet of colour, and together form a picture as pleasing and effective as it is possible to imagine. Planted in the way described, provided that it is possible to lower the water in the ponds in the winter time a foot or so to permit the base of the plants to remain comparatively dry, the Lobelia—at any rate in the south and south-west—will continue in these positions undisturbed all the year round. During the hot summer and autumn months, the plants delight in having the water about their roots, and, in fact, do not resent being slightly submerged. For the ornamentation of formal ponds and tanks, nothing can be better than well-filled boxes of these Lobelias tastefully arranged in informal groups, standing on supports either of bricks or drain pipes in the water, just allowing the surface to cover the top of the soil, which, in conjunction with groups of Water Lilies, can be made very effective. In October these boxes can be easily removed to a cold frame or some dry sheltered position for the winter.

Propagation.—The present is a good time to raise plants from seed. The seeds should be sown in shallow boxes or pans, and placed in a cool, shaded frame to germinate. As soon as the seedlings are large enough to handle, they should be potted off singly. During winter they should be given the protection of a cold frame, and by May or June of next year they ought to be fit for planting out into their flowering positions. Where there is a sufficiency of old plants, propagation is best accomplished by division of the roots, or by cuttings, which can be done very readily in the spring. The mode usually practised is to put the divisions or cuttings into single pots, and then to plunge them in moderate bottom heat in the frame of the propagating house. The affording of water must be carefully attended to during all the growing season, as the lack of moisture at their roots would be detrimental to these species of Lobelia. The soil they thrive best in is a rich loamy soil strengthened with the presence of good cow manure.

Varieties.—Splendens, often referred to as a species, is in reality a variety of L. fulgens, and is well worth growing for its beautiful flowers of exquisite colour. Other varieties of L. fulgens which should not be omitted from one's collection, and which are undoubtedly superior to the types are "Queen Victoria," possessing immense, deep vermilion flowers with red-tinted foliage; "Firefly," bright crimson flowers; "Violacea," reddish-violet flowers, with red foliage; and "Heavenly Blue," which is distinct from the rest in having clear, light-blue flowers. All these plants grow about 3 feet in height. The best varieties of L. cardinalis are "Crimson Beauty" and "atrosanguinea." The former is a lovely variety, with deep red flowers and very effective dark red foliage, while the latter is a beautiful dark form of the type.

THE KITCHEN GARDEN.

By J. GIBSON, Gardener to His Grace the Duke of PORTLAND, Welbeck Abbey, Notts.

Spring Cabbages.—The first sowing of these must now be made without further delay. Let the utmost importance be attached to having the soil in a suitable condition as regards tilth and moisture. Water the ground well before sowing rather than apply water directly afterwards.

Turnips.—Sow a large breadth of this vegetable to help in maintaining a regular supply of fresh produce until the winter has well commenced. Fork the ground over, and when the lines have been drawn, well water them before sowing the seeds. Select the varieties "Snowball" or "Model White," together with Golden Ball for sowing at this date, and for a later supply the old variety Chirk Castle, which is one of the best for withstanding the winter.

Runner Beans.—Plants having now topped the stakes, they should be closely pinched back, both on the top and side growths. Loss is often occasioned by the overcrowding of the shoots. Topdress the lines with litter, and apply ample supplies of water.

Carrots.—Still another small sowing may prove very useful late in the season, selecting one of the earliest varieties, as Immitable Forcing or Early Nantes, the former yielding small round roots, and the latter longer roots, but splendid in colour.

French Beans.—There is still time to sow another succession of these, but it would be well to sow them in a position where they could be easily afforded protection from frost, should this prove to be necessary. Frames containing no crop may be made good use of now by sowing such seeds in them, and growing them as if in the open, but having the sashes ready for covering the frames when the autumn weather demands it.

THE HARDY FRUIT GARDEN.

By W. A. COOK, Gardener to Sir EDMUND G. LODER, Bart., Leonardslee, Sussex.

Fig Trees.—Examine these and remove the points of the strong shoots again. Expose the fruits as much as practicable, and take away all shoots that will not be required in the future. If the young shoots are thinned out sufficiently at the present time but little further thinning will be needed this season. Make all shoots secure to the wall. Any long ugly shoots, which may have perhaps only a bunch of leaves on the top, may be conveniently cut away at this time. If the roots are confined to restricted borders, a thorough soaking with a liquid will be an advantage to the swelling fruits. The liquid may be such as is obtained from the sewage tank, or even clear water.

Peaches and Nectarines.—Let the fruits of mid-season varieties be exposed to the sunshine as much as possible, in the same manner as was adopted for earlier ripening varieties. The process of propping up should be carried out on each tree about three weeks before the fruit will be ripe. Afford abundance of water to the roots and well syringe the foliage daily. A few waterings with the XL-All graduating manure would do good.

Autumn Fruiting Raspberry Belle de Fontenay.—Thin out the growths (canes) of this, leaving only the best and strongest. The plants will produce a good supply of fruit during October, but they need moisture and much mulching.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower to Sir TREVOR LAWRENCE, Bart., Burford, Surrey.

Sobralias.—These Orchids, remarkable for the size of the individual flowers, are beginning to find more favour with cultivators. At several recent shows of the Royal Horticultural Society they have been greatly admired. There are many species which are well worth including in a collection of Orchids, as S. macrantha, its pure white variety Kienastiana (alba), S. xantholeuca, S. Holfordi, S. Sanderiana, S. Lindeni, S. Lucasiana, and S. Ruckeri, to which may be added the following hybrids: S. Veitchi, S. Wigamæ, S. Amesiæ, &c. Several of the smaller flowering species are pretty, but the flowers are more fugacious. Such are S. virginalis, S. Warscewiczii, S. lilliastrum, S. violacea alba, S. speciosissima, &c. As a rule the individual flowers of Sobralias do not last in good condition more than three or four days, but each reed-like stem will produce in succession from three to six blooms, so that a good-sized specimen plant will for several weeks have from six to a dozen blooms in almost perfect condition each day. Sobralias have usually strong fleshy roots, and, being terrestrial plants, require plenty of pot room. Those which have become pot-bound and are obviously suffering from want of root space may be re-potted at any time, being careful not to injure the roots, which are now growing freely, more than can be avoided. Early spring is probably the most suitable time for dividing large specimens. The pots should be furnished with 2 or 3 inches deep of crocks for drainage, and for potting let the compost consist of lumpy fibrous peat and rough sandy loam in equal parts, mixing a moderate quantity of broken crocks to ensure porosity. The soil should be made moderately firm, pressing it down to half an inch below the rim of the pot, thus leaving space for affording water, which is required in quantity during the growing season. Sobralias succeed well in a light position in the intermediate house the whole year round, but in winter the leaves are liable to become spotted and unsightly if the atmospheric temperature is allowed to fall for any considerable length of time below 55°, especially if the atmosphere of the house is naturally damp.

REPORT ON THE CONDITION OF THE OUT-DOOR FRUIT CROPS.

[FROM OUR OWN CORRESPONDENTS.]

THE WORDS "AVERAGE," "OVER," OR "UNDER," AS THE CASE MAY BE, INDICATE THE AMOUNT OF THE CROP AND "GOOD," "VERY GOOD," OR "BAD," DENOTE THE QUALITY.

FULLER COMMENTS WILL BE GIVEN IN THE FOLLOWING NUMBERS. SEE ALSO LEADING ARTICLE ON PAGE 70.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, *as well as specimens and plants for naming, should be addressed to the* **EDITOR, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Special Notice to Correspondents.—*The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.*

Illustrations.—*The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c., but he cannot be responsible for loss or injury.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.*

Local News.—*Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

APPOINTMENTS FOR THE ENSUING WEEK.

MONDAY,	July 30	R.H.S. Conversazione in Vincent Square Hall, 9 p.m.
TUESDAY,	July 31	Roy. Hort. Soc. Coms. meet. Opening of International Conference on Plant Breeding in R.H.S. Hall, 10.30 a.m. Dinner at the Hort. Club, 6.30 p.m.
WEDNESDAY,	Aug. 1	Continuation of Conference in the morning and visit to Burford Gardens in the afternoon.
THURSDAY,	Aug. 2	Closing day of Roy. Hort. Soc. Conference. Banquet in the Roy. Hort. Soc. Hall, at 6.30 p.m.
FRIDAY,	Aug. 3	Visit of Conference guests and others to Gunnersbury House Gardens, Acton.

AVERAGE TEMPERATURE for the ensuing week, deduced from observations of Forty-three Years at Chiswick—63.3°

ACTUAL TEMPERATURES:—

LONDON.—*Wednesday, July* 25 (6 P.M.): Max. 74°; Min. 56°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—*Thursday, July* 26 (10 A.M.): Bar., 30.0; Temp., 72°; *Weather*—Fine.

PROVINCES.—*Wednesday, July* 25 (6 P.M.): Max. 68° Eastern Counties; Min. 54° Orkneys.

SALES.

TUESDAY—
Freehold Properties comprising Modern Farm Building, Freehold Cottages, Pasture, Meadow Grazing, and Woodland, at Fambridge-on-Couch, by Protheroe & Morris, at 2.

FRIDAY—
Orchids in variety, at 12.45. L. Harnisii, Roman Hyacinths, Narcissus, &c., at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 3.

SATURDAY—
Freehold Horticultural Property, Mount Pleasant Nursery, Hailsham, Sussex, at Gildredge Hotel, Eastbourne, by Protheroe & Morris, at 4.

Our Fruit Crops.

By the courtesy of our correspondents in all parts of the British Isles we are enabled to lay before our readers a tabular statement which will enable them to form a generally accurate notion of the condition and prospects of the fruit crops for the present year. Those who require a detailed account will find it on p. 64 and subsequent pages. For others the tabular summaries will probably suffice. The general result is bad, perhaps not quite so much as we had feared, for Apples yield something approaching to half a crop, and in as many as forty cases they are recorded as above the average. Scotland and Wales come out very badly as regards this the most important fruit-crop of the year, but England has been more favoured. This is especially noticeable in Devonshire, which county has a similar record as regards Pears, which, although unusually deficient in most counties, are better represented in Devon. Plums are almost a total failure everywhere. "Small fruits" are not specified individually in the table, but collectively the record is not a bad one, though many correspondents state that Raspberries have done well, whilst Gooseberries have not maintained their usual reputation. Strawberries, in spite of the injury inflicted on the early blossoms, have not done badly on the whole, for the Strawberry provides a succession of flower-buds, so that if the earliest get injured the latest ones escape unscathed. Some remarks on this subject will be found on another page (page 72), to which we direct the attention of the reader.

An unusual number of forms has been returned to us too late to enable us to avail ourselves of them on this occasion, but it is believed that these omissions would not materially affect the general averages. We may have an opportunity in subsequent issues of making use of the information obligingly supplied by our correspondents.

There can be no doubt that in this year the calamity is attributable in the main throughout the whole country to the inclement weather during the flowering season, as indeed it generally is, but there is work for our meteorologists to determine the connection between the autumn climate of last year and its effect on the maturation of the wood and the development of the flower-buds, as well as to indicate the relations between the spring weather and the condition of the flowers at the period of expansion. Some of our Devonshire correspondents might be able to explain the relative immunity of the Apple and Pear crops in that county from the general disaster.

Some of our Belgian colleagues, we see, have been inveighing against the stupidity (*bêtise*) of plants, which never learn by experience, but which year by year seem unable to adapt themselves to circumstances and become more or less the victims of unpropitious circumstances.

It is very nice to have something upon which to cast the blame, but is it certain that we hybridists and cultivators are not as much or more in fault than the so-styled stupid fruit trees? The raising of late-flowering varieties and the selection of sheltered localities are certainly not entirely outside our capabilities.

To look at the matter from another point of view, has not the consumer, at any rate, the right to rejoice that the deficiencies of the home crops can be and are so fully compensated for, not only by foreign importations, but also by the vast quantities sent us from our own kith and kin across the oceans?

In sending out the fruit-forms we availed ourselves of the opportunity of obtaining the opinions of our correspondents on the important subject of summer pruning. In a subsequent number we shall summarise the information so obligingly communicated, but we may here remark in passing that the answers show that there is considerable difference of opinion as to the value of the results obtained from the practice, just as there is divergence of practice in the time and method of carrying out the operation. The results are described by some correspondents as "indifferent" and by others as "most satisfactory." It appears that the system is most popular in early districts, and least beneficial in cold, late localities where the soil and climate are adverse. So far as we have yet studied the replies they confirm our opinion that in many instances in which summer pruning has proved unsatisfactory the operation has been carried out too early in the season and has therefore been followed by secondary growths which are extremely undesirable.

OUR SUPPLEMENTARY ILLUSTRATION.—There is no more effective waterside plant than Lythrum Salicaria, the spiked Lythrum or Purple Loosestrife, which grows wild in this country in wet ditches and marshy places, and flowers freely and continuously in summer. There are garden varieties of it with colours of a more pleasing shade, but the wild type is quite showy enough to be worth a rod or so of ground wherever there is water. It grows from 4 to 6 feet in height and is easily multiplied by division or cuttings. Lakes, ponds, streams, and riversides might easily be made much more charming than they generally are if only such plants as the Loosestrife, Flag, Yellow Iris, Rodgersia, Globe Flower, Primula japonica, Iris lævigata, and I. ensata, Caltha, Arundo conspicua and A. Donax, Osmunda, and other Ferns were utilised for such positions; the plants would be at home and they would beautify their surroundings. This kind of gardening is possible only where rats and water-fowl are kept in check. At Kew, writes a correspondent, numbers of visitors appear to find more pleasure in gazing at a peacock's tail or the movements of geese and ducks than in plants, consequently there are more birds than is good for waterside gardening; but in private places this difficulty would not arise. What a lovely garden might be made with the hosts of plants that grow best in or within easy root-reach of water, and yet, so far as we know, no such garden has yet been attempted. The lake at Kew would be an ideal spot for a water garden if only the geese, &c., could be sent to the Zoo! After all, there is as much reason for keeping herds of deer, goats, &c., in the garden as there is for keeping destructive birds. A few monkeys, parrots, and perhaps a tiger would be equally appropriate in the Palm-house, at any rate the crowds would prefer them to the plants.

DR. AUGUSTINE HENRY left Liverpool on the 25th inst. for British Colombia, Oregon, &c. His object is to study some of the interesting trees in that country, which are of so much importance from the point of view of practical forestry.

FLOWERS IN SEASON.—CARPENTERIA. Mr. KINGSMILL, of Harrow Weald, kindly sends us a specimen of this shrub, with large finely developed flowers. The plant has been growing outside and unprotected for the last eighteen years, and is now a large shrub.

THE MIDLAND CARNATION AND PICOTEE SOCIETY.—We may remind our readers that the Midland Carnation and Picotee Society's show will be held at the Botanical Gardens, Edgbaston, Birmingham, on Wednesday and Thursday next, August 1 and 2. Particulars can be obtained from Mr. T. HUMPHREYS, hon. secretary and treasurer, at the address already mentioned.

NURSERYMAN AS JUSTICE OF THE PEACE.—Mr. T. G. BAKER, head of the firm of Messrs. BAKER'S, Nurserymen and Seedsmen, Wolverhampton and Codsall, has just been appointed to the Commission of the Peace for the borough of Wolverhampton. Mr. BAKER was for many years head of the firm of JAMES BAKER & SONS, Ltd., boot manufacturers, but some years ago severed his connection with the boot trade and established a first-class nursery at Codsall, and florist and seed shops in Wolverhampton. Mr. BAKER is also an honorary member of the British Gardeners' Association.

NATIONAL POTATO SOCIETY.—Mr. WALTER P. WRIGHT having been appointed Horticultural Superintendent at the South-Eastern Agricultural College, Wye, Kent, has resigned his position as secretary to the above Society. The College will gain what the Society will lose. Mr. W. H. ADSETT replaces Mr. WRIGHT as secretary, and Mr. FOSTER, of University College, Reading, is the treasurer.

FRUIT SALES IN AUSTRIA.—A very useful work is carried out in Austria during the fruit season with regard to the selling and buying of fruit by the Fruit Cultivators' Society, which distributes, free of cost, all over the empire, the current prices of fruit, and replies to all matters concerning the fruit trade as well as negotiates sales. At the present time large quantities of Cherries are being offered for sale by the Fruit Sales Agency, whose offices are at Kornenburg, Vienna. Why have we nothing similar on this side of the Channel?

THE LATE COUNT DE KERCHOVE.—As was to be expected, the Council of the Royal Agricultural and Botanical Society of Ghent is taking steps to perpetuate the memory of their late zealous and enlightened president, and is invoking the aid of those who have been in the habit of taking part in the "Ghent Quinquennials." We shall probably be in a position to give more explicit particulars later on. In the meantime we are sure the movement will have the earnest sympathy of all those who were brought into relation with the deceased president.

THE DEPARTMENT OF AGRICULTURE OF THE MALAY STATES.—We note the publication, by Mr. J. B. CARRUTHERS, of the first Report of the Department of Agriculture of the Federated Malay States. As this department, says Mr. CARRUTHERS, was only initiated in June, 1905, this report must necessarily be of a more prophetic than historical character. Some useful work, however, has been done, and preparations made for future work when the department is fully equipped. Its functions are:—"1. The study of various physiological and pathological botanical questions bearing on the economic plants of the Malay States. 2. The care of the health of all cultivated plants, and constant watch for the earliest signs of any disease, that steps may be at once taken to eradicate it. 3. The carrying on of experiments in agriculture and horticulture. 4. The introduction and trial of new economic plants suitable for profitable cultivation, and the distribution of seeds and plants of these to those wishing to begin the cultivation. 5. The giving of advice and information on agricultural, botanical, and horticultural questions."

ELECTRICITY AS APPLIED TO AGRICULTURE.—Readers may remember the article we published in the early spring describing the experiments being carried out at Bevington, near Evesham, in regard to the use of electricity in growing corn-crops, and it may interest them considerably to know how it is progressing. Mr J. E. NEWMAN, the engineer in charge, states that unfortunately some portions of the apparatus was delivered late, and temporary arrangements had to be made; consequently, breakdowns occurred, and instead of working eight or ten hours a day, the average between March 16 and May was only four. Various troubles incidental to all experimental work occurred, so if under the circumstances an increase in the yield can be recorded, there bids fair to be an excellent result another season when everything is "ship-shape." In the Wheat field, it may be remembered we stated that 19 acres had been planted; these were of two sorts, viz., English white, electrified, 9 acres; unelectrified, 1½ acres. Manitoba, electrified, 3 acres; unelectrified, 5½. Sowing took place in February, and the current was turned on in March, when the plants were well showing. The ground had been somewhat trampled upon while the poles and wiring were being erected, and this did not improve the crop. So far the crop promises well and should prove quite 30 per cent. heavier, while the yield of straw is considerably greater. On the electrified portions of the field, the noticeable difference is better stooling, which results in a larger number of ears, but at present it is not noticeable that the number of grams per ear or the size of ear has increased. The straw is from 4 to 8 inches taller, and the plant itself is apparently stronger, but it was no earlier than the unelectrified part. The difference in the Manitoba yield is more noticeable, though with the Barley it is not observable on account of disturbing factors. As to the manure used, last autumn the part experimented upon was fertilised with farmyard manure, while artificials were used on the control part in the spring. It is practically impossible to say if it will pay until the crops are in, and the actual increase is known. It depends entirely upon what the increase of crop, minus the running expenses and depreciation, will pay on the capital expended. A one horse-power plant will supply 50 acres, and running expenses are not a considerable item, and, of course, depreciation of the plant should be small. Installation varies according to local conditions, but it should vary from £15 to £20 per acre for areas up to 10 acres, and £5 per acre for 100 acres.

LINCOLN PARK. We learn from the American journals that the Kentucky farm where ABRAHAM LINCOLN was born has been secured for the nation, and that it will be developed as a public park. It comprises an area of about 110 acres, which are to be laid out by Mr. GUY LOWELL, of Boston.

THE BOTANICAL MAGAZINE.—We learn that Mr. HEMSLEY is only responsible for the very interesting historical introduction to the *Botanical Magazine*, and that the index itself was not compiled by him. This is to be regretted, as various corrections and critical notes, which have accumulated at Kew, have in consequence been omitted.

PLANT FOOD REQUIREMENTS OF BEARING FRUIT TREES.—The New York State Experiment Station has, says the *National Nurseryman*, recently made an investigation of the food used by bearing fruit trees during one season's growth. This investigation included the Apple, Peach, Pear, Plum, and Quince. The figures seem to show that "the relative proportions of the different plant-food constituents are approximately the same for the different varieties of fruit trees. This means that, under like conditions of soil fertility, a mixture of nitrogen, phosphoric acid, and potash which would meet the requirements of one variety would also meet the needs of the other varieties, so far as the supply of these plant-food constituents is concerned. What particular proportions are best adapted to meet the needs of any particular soil can be determined only by special experiment." The amount of plant-food taken from the soil per acre by the different crops and compared with wheat is shown in the following table:—

Variety.	No. of trees per acre.	Nitrogen, pounds.	Phosphoric acid., pounds.	Potash.
Apple ..	35	51·5	14·0	55·0
Peach ..	120	74·5	18·0	72·0
Pear ..	120	29·5	7·0	33·0
Plum ..	120	29·5	8·5	38·0
Quince ..	240	45·5	15·5	57·0
Wheat ..	*20	39·5	12·0	16·2

*Bushels.

This demonstrates that the Peach uses the largest amount of plant-food. The pome fruits give results much alike. But all of the fruits use more food than will an acre of Wheat yielding at the rate of 20 bushels of grain and a ton of straw. The moral is, therefore, that our acre of fruit trees should receive larger amounts of fertiliser than the same area of Wheat. Yet the practice is in many sections to fertilise for Wheat and let the fruit trees take care of themselves.

PHENOMENAL HAILSTORM IN IRELAND.—In the early afternoon of June 28 the inhabitants of Ballinora were suddenly enveloped in intense darkness. Only a few seconds more elapsed, and the hail, or rather the fragments of ice an inch in diameter, beat the earth with a tremendous force. The writer has seen Potato gardens with not a stalk left standing—cut down as if by the hand of the mower. The Oat crop has suffered in a similar manner. Mangels and Turnips met the same fate, but the latter show some signs of recovering, and, owing to the long time for growth yet before them, may not result in serious loss. It appears to have been at its height in the Ballinora and Ballincollig portion of its course, as evidenced by the great destruction in those places, trees 12 inches in diameter having been smashed half-way from the base. The time taken by the cyclone to pass over a given point was about ten minutes; the breadth or diameter of the spiral, judging from its destructive effects, could not exceed quarter of a mile, and the edges must have been well defined.

GERMAN NURSERYMEN.—The Society of German Nurserymen (Verband der Handelsgartner Deutschlands) announce that the office of the Society has been removed to 97-98, Bergstrasse, Rexdorf, Berlin. Herr BECKMANN is the general secretary.

BRITISH GARDENERS' ASSOCIATION. At the last meeting of the executive council of this association, Mr R. HOOPER PEARSON in the chair, 24 new members were elected, bringing the total number up to 925. Mr. W. H DIVERS, head gardener to His Grace the Duke of PORTLAND, Belvoir Castle, Grantham, was unanimously elected chairman for the ensuing year, and Mr. R. HOOPER PEARSON, vice-chairman. Several members of the association having enquired if a tour round the gardens and nurseries in Belgium could be arranged this year, under the auspices of the society, the council considered the time now at their disposal was insufficient for making proper arrangements. The secretary, however, was requested to obtain information with a view to arranging a continental tour for gardeners in 1907. If it is possible to make arrangement for meetings of the association during the Shrewsbury show in August and the Edinburgh show in September, this will be done in order to bring the objects of the association before gardeners in the provinces, and to combat the erroneous views that still prevail in many quarters on this matter.

THE PREVENTION OF COMMERCIAL CORRUPTION.—The House of Commons lately passed through its final stages a Bill, the necessity for which is generally acknowledged. The facts brought to light startled the public at the time, but many of them now are only too familiar. The late Lord Chief Justice RUSSELL OF KILLOWEN gave instances of goods being wilfully destroyed by corrupt employés in order that they might get a fresh commission on a fresh order. He showed that throughout our commercial and industrial life the practice of secret commissions was creating, and still is creating, gross dishonesty, and he demonstrated that without an amendment of the law the evil would grow worse, for the dishonest would drag down the honest. The present Government, to its credit, declined to allow the opposition of a few members to stop so important a measure. Whether the Bill will do all that is hoped from it remains to be seen, but it at any rate, says the *Daily Graphic*, stamps as a crime a form of corruption which is a disgrace to the character of our commercial life. We do not see how foreign dealers are to be prevented from offering illicit commissions and discounts, or how the consciences of the recipients are to be awakened.

The Thoughtlessness of Plants.—"Indeed," says the *Moniteur du Jardinier*, "what thoughtless things fruit trees are. Every year the sun and wind play the same tricks, and every year the plants are deceived by them. For centuries past March weather has been at first fine and spring-like. Then, despite precedents, almanacks, past experience, proverbs, without even consulting newspaper reports, all of them—Peaches, Almonds, Plums, Pears, Apples—clothe themselves in their beautiful white, rosy, or red blossoms. They are admired, for they are exquisite, fresh, beautiful, in the youth of the year. A week passes, frosts set in—result, faded flowers and a bad crop. Old as well as young, untaught by experience, next year the flowers again begin the same proceedings, untaught and unteachable." So says our contemporary, but if the plants could speak would they not say that the cultivators are equally heedless of experience?

Index Kewensis.—We are glad to announce the publication of the fourth and concluding part of the first supplement as prepared by Messrs. Durand and B. Daydon Jackson. This brings the list down to the end of 1895. The delay in publication is, we regret to learn, attributable to the impaired eyesight of M. Durand, who says that the correction of the proofs has entailed on him much suffering.

Summer Holidays.—There is much talk of holidays at this time of year, so intending travellers may be glad to obtain information concerning the many beautiful and restful places to be found by "Doctor East Coast," and, further still, in the same direction, via the Hook of Holland to the Continent in general. Mr. Percy Lindley's new guide book, published by the Great Eastern Company's authority, is quite as attractive as its predecessors. It is, indeed, apparently an enlarged form of them, with coloured pictures added. The information is practical as well as eulogistic, and those choosing a place wherein to pass the summer holidays may be advised to consult its pages.

Flowers in Season. On the 25th inst., we received a large bunch of flowers of Chrysanthemum maximum from Mr. G. Hawley, Brookfield Nursery, Swinton, near Rotherham. This hardy species is one of the best border plants for cultivation where the soil is rich and moist, but if at all starved much of its handsome habit is destroyed. There are now many varieties with larger flowers than those of the type, and presumably they have all arisen by selection. The varietal name attached to the flowers received is that of Britannia, and they have certainly been most liberally cultivated.

Fig. 29.—Strawberries at the station waiting to be unloaded.

Fig. 28.—Packing the strawberry fruits.

THE STRAWBERRY CROP.

In spite of the gloomy prognostications concerning the Strawberry crop, the season that is now over does not appear to have been very much below the average. May frosts took their usual toll, but that is an event which we ought to regard nowadays rather as the rule than the exception. Every year when the bloom is out frosts occur somewhere in England, not only in May, but even in June. This year there was a sharp frost in the Southampton Strawberry-growing district on June 2, but it came too late to do any serious damage, as most of the fruit was set. A single frost, indeed, seldom does any great amount of harm. It will probably destroy a large number of the blooms that are actually out, but others will be protected by the foliage, and those that are already set or not yet open will not take any harm, unless the frost be something very exceptional. It is fortunate that the Strawberry plant does not produce all its blossoms at the same time, for if that were so the chances of a spring frost destroying the crop at one fell swoop would be far more often realised than at present.

As for prices, they have been as low as ever this year—a sure indication that the supply has not been insufficient to meet the demand. Even at the very beginning of the season, when the Southampton crop had only been on the market a day or so, one might have seen Strawberries being sold at 3d. and 4d. a pound on the barrows in the streets. The fruit was not, of course, of the best quality, but it was passable, and if there was a profit at all on the retail price, the grower must have received very little. In the shops at the same time the best berries were fetching 10d. to 1s. a pound, while a few selected baskets of about three-quarters of a pound each could be had for 1s. to 1s. 6d. apiece, according to the time of day and the freshness of the fruit. Smaller berries, or "seconds," and rather "squashy" at that, brought 6d. a pound, and a little later went so low as 4d. Then the glut came, as it always does, and best fruit could be had for 6d. a pound, and fairly good berries at 4d. Retail prices do not generally go much below that, but the figures of the retail shopkeeper are not always a true guide to the

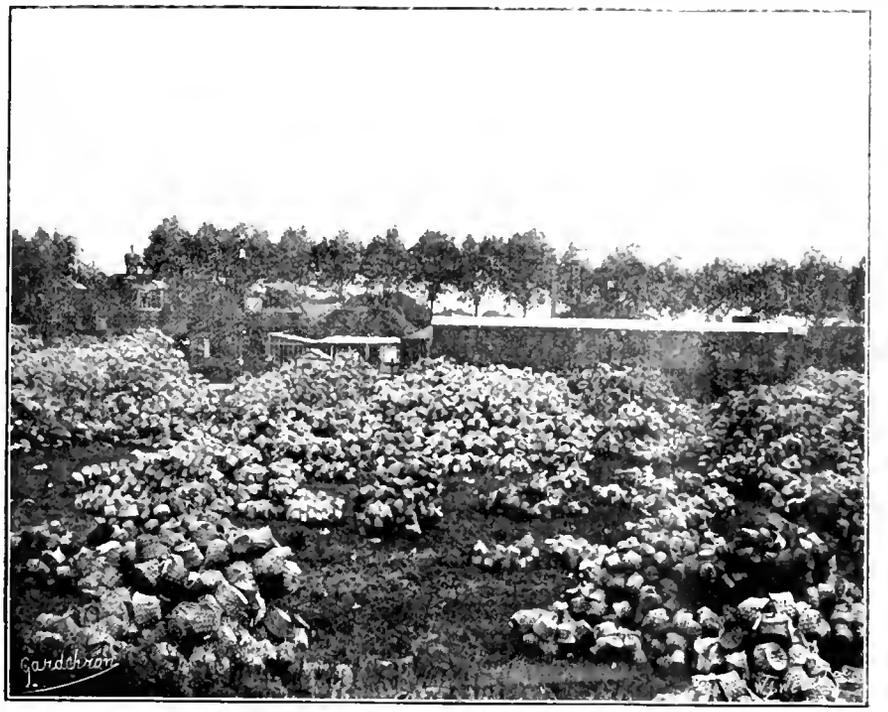

FIG. 30.—"RETURNED EMPTIES" AT SWANWICK STATION (L. AND S.W. RY.).

state of the market at the moment. He has to think of yesterday and to-morrow, and to make the good days compensate, if possible, for the bad.

At the height of the season the Southampton growers were receiving from about a shilling to eighteen-pence a gallon for their fruit, a gallon being anything between 5lbs. and 6lbs., without any special weight being guaranteed. It would be better if these "reputed" gallon baskets were made to a specified standard, so that they could contain a guaranteed weight of fruit, and not, as now, just as much or just as little as they will hold. The grower would benefit if this standard of weight were adopted, because the purchaser would know exactly what he was buying. At present the retailer, as well as his customer, "buys a pig in a poke." Six pounds of fruit is "supposed" to go to the gallon basket, and the fruit is usually sold just as it is received from the grower, without being handled in any way. This, of course, is a great advantage in the case of an easily damaged fruit like the Strawberry, but the system has the drawback referred to. Strawberries picked in this way are usually sold, "basket and all," and the purchaser cannot tell, except roughly, how much fruit and how much basket he is buying at so much a pound. The baskets themselves vary greatly in size and weight, and sometimes they are not absolutely dry, for it is no uncommon sight to see them left out in the rain or in open sheds, where they are only partially protected from weather. The Kent grower, who sells his fruit by weight in bulk, and not by reputed measure, gives better value to the purchaser in the matter of weight, but not in quality, because in most cases the Strawberries have to be handled again before being delivered to the purchaser. Peck-baskets, as used in Kent and Sussex, are of the ordinary flat market shape as used for Peas and other bulky crops, and they are by no means the best kind of packages for the marketing of such easily-bruised fruit as Strawberries. These baskets contain 12 lbs. of fruit, but few purchasers require so much fruit at a time, except for jam-making. The result of this is that the Strawberries are bundled out of their baskets into a large tray, from which they may be scooped up as wanted. As a result of the turning-out process and the subsequent scooping up, the fruit is badly damaged, and is never worth as much as that which is sold in the original packages as it left the gardens. It seems surprising that the Kentish growers have not long ago appreciated this fact, and adopted the handle basket for marketing their fruit. Perhaps they are influenced to some extent by the fact that the railway companies are always ready to grant a low rate for the carriage of fruit packed in the larger flat baskets, but this surely must be very false economy on the part of the grower. It is much easier for the railways to handle fruit of any sort in 12-lb. flat packages than in baskets of half the size and weight with handles. The former take up less room, weight for weight, than the latter, but it is obvious that no one, even if more careful than the ordinary railway porter usually is, can handle the heavier packages without handles as gently as the lighter baskets with them, and the natural result is that the peck-baskets get dumped down far more roughly than the others to the great detriment of the fruit within. There cannot be any doubt that the Southampton growers market their fruit under better conditions. They may have to pay a higher rate for using the handle baskets, because the railway company have to put up special vans with shelves to carry this sort of traffic, but the better condition of the fruit on arrival at the market should amply repay the extra labour and expense involved. If the Hampshire grower could improve his methods still further by using baskets of one uniform size with a guarantee to the salesman (and the subsequent purchaser) as to the nett weight of the fruit, the kind of package he employs could hardly be improved upon.

In this branch of the fruit industry, however, we again find the fault which is so common a feature of the fruit trade in England. Foreign fruit-growers—especially the French and the Americans—have long ago recognised the value of grading their fruit according to size and quality. Not so the Englishman, who is very slow to learn a lesson which has been brought home to him so bitterly on many occasions. The home grower still persists in attempting the old fraud of placing the best berries on the top and the inferior ones down below. It is a system of deception which deceives no one, if one may be permitted the contradiction of terms. The salesman knows all about it, the retail shopkeeper learned the trick the very first time he handled a basket of British fruit, and the customer is never [?] imposed upon by the practice. Why, then, is the British grower so persistent in his obstinacy? There is no need to grade fruit too closely, but there should be a severe line drawn between good and bad—"firsts" and "seconds." It is no good putting damaged, unripe, misshapen, or small fruit at the bottom of the basket, in the hope that it may not be discovered. Someone is bound to come across it, and a dissatisfied customer will be the result. And it should be remembered that every time a customer is dissatisfied with British fruit he is tempted to patronise the foreigner. This remark applies to every kind of fruit as well as to Strawberries. The average customer does not care whether he buys fruit of British or foreign origin so long as it is good and reliable. Sometimes, of course, he has to buy what he can get, but when he has the choice he is more likely to buy good foreign Cherries than bad English Strawberries, and properly-graded American Apples in preference to a lot of English nondescripts of five or six different sorts all bun-

FIG.—31.—A GOOD USE FOR OLD "THIRDS."

dled anyhow into one basket. The English grower has plenty to learn yet in the matter of marketing his fruit, especially as regards grading and careful packing.

Few people have any idea of the magnitude of the Strawberry industry of the present day, but the importance of the business may be well gauged by a glance at the following figures, kindly supplied by the London and South-Western Railway Company. During last season no fewer than 1,480,000 baskets of Strawberries were despatched from the district near Southampton, which includes the neighbouring places of Bursledon, Swanwick, Wickham, Fareham, Botley, Sholing, &c. This huge number of baskets, the aggregate weight of which came to about 3,400 tons, required an average of six special trains a day at the height of the season to bring it to the market. London took about half of this gigantic crop, and the rest of it went to the large towns of the Midlands and the North. Scotland is also a good customer, and repays in some measure the amount she consumes by sending to the South, after the English crop is over, the bulk of the crop grown in the neighbourhood of Glasgow, where the Strawberry does well. And yet, in spite of these astonishing figures from the Southampton district, last year's crop was below the average, owing to frosts. The counties of Kent and Sussex also supply the large markets with consignments of Strawberries, and Cornwall does a small part of the business early in the season. But for extensiveness of cultivation, the Hampshire Strawberry-grower is easily first, and his crop is generally in the market a week before the Kentish berries are ready. The most surprising thing about it is that the gravelly soil around Southampton is fit for very little else except Strawberry growing, and it is not so very many years ago that the now prolific fruit gardens were nothing but a waste of gorse and rank grass hardly good enough to keep the hungry donkeys and horses of the gipsy folk who encamp thereabouts. *East Sussex.*

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

CEREUS CANDICANS.—Thinking it may perhaps interest some of the many readers of this paper I beg to make a few remarks on this plant. Having two in my possession and both flowering this year, I was surprised to find the flowers were very different, although the plants are just the same in appearance, and have been here many years, with a few other varieties. There is some difference in them as to size, one having flowered several times—the smallest one; this is 4 feet or more long, and the other 6 feet or more. The longest one flowered for the first time this year, after over fifty years' attention and care. The flower was very much smaller, and the petals narrower and stiffer. The other plant had a large reflexed flower, broader petals, and a longer foot stalk, but they were not measured or touched. Perhaps some of your readers may have had these in flower and noticed. I am no botanist, and only grow a few plants for recreation and love for them, and sometimes they show me their beauties. My days are declining, and they are now much neglected, I am sorry to say. *J. C., Didcot.*

AGAVE CELSIANA NANA.—This very pretty dwarf plant flowered with me last year, but the leaves did not show signs of decay, and after a time it made a move close to the old stem, which is now producing four young buds, whilst the old leaves still retain the sound condition they had before flowering. The original plant flowered many years ago, and produced two plants in the same way; but after being taken off one of these rotted, through some unknown cause. My present plant is in a very small pot for an Agave. I grow some in saucers, when it is difficult to water them in the pots, as the leaves are very close to the soil, making it difficult to give them water. I have found most that have bloomed had the saucers. I have just made two pots of the A. Ousselghemiana that flowered some years ago, and produced two, close to the stem; also the variegated variety. I am fond of Agaves when they are not too large, but should not object to the others if I had plenty of room, as they are very grand plants. I have a few now—some very rare, and not new either. *J. C., Didcot.*

CHILDREN'S EXHIBITS AT THE HANLEY SHOW.—A very interesting section of the Hanley Show, of which a report was published in the last issue of the *Gardeners' Chronicle*, was that devoted to exhibits by children. The exhibitors were confined to those attending the schools in the county borough of Hanley, and it was most gratifying to the promoters to find that this year there were no fewer than 2,200 entries. The classes were for window plants, wild flowers, leaves of trees, and grasses, and the material got together was remarkable, considering the surroundings of the neighbourhood. All kinds of pots and other utensils had been pressed into service for the rearing of the plants, one exhibitor, through lack of a more suitable receptacle, had grown her plant in a meat tin. Some of the children had walked many miles to gather the leaves and grasses, because several of the varieties exhibited are not to be found within a wide radius of Hanley. This exhibition is certainly a step in the right direction, and those who are striving to encourage a love among the young for flowers, and for the study of wild flowers and grasses of the district, are to be congratulated on the success of this section of the Hanley Show. *C.G.H.*

YELLOW-GROUND PICOTEES (see figs. 32 and 33).—Of all the dainty flowers ranged under the head of Dianthus none can excel the yellow-ground Picotee, with its rich edging of carmine or deep crimson, and sweet perfume. Mr. Nigel is one of the best of these, a large flower heavily edged with crimson. Gronow is a blossom of perfect form in primrose-yellow edged with carmine, and Amphion is more deeply marked with the same tint on a pale apricot ground. These charming flowers should be more often seen than they are; in any ordinary soil they will flourish if planted in October, the border being previously well trenched and manured. Good drainage is essential, and to a damp, heavy soil, burnt vegetable rubbish and crushed mortar should be added. Soot is a chemical manure which suits all Carnations if mixed with their compost. Moreover, it is inimical to their special enemy the wire-worm, and therefore it is also of value in this direction. Dalkeith, a very similar blossom to Mr. Nigel, is one of the finest of the late introductions, and Louisa is of specially fine form, with a narrow margin in rose colour. *I. L. R.*

WATER GARDENS.—In Mr. Mallett's article on this subject (p. 322), I note that Polygonum sphærostachyum (= P. macrophyllum according to *Index Kewensis*.—ED.) is mentioned in connection with P. cuspidatum as being "eminently fitted for planting by the water's edge." In the case of the first-named, this must be a literal error. Probably P. polystachyum is meant. Polygonum sphærostachyum is a rare and beautiful species from the Himalayas, and is one of the most attractive rock plants in cultivation. Scarcely 6 inches in height, the brilliant carmine-scarlet or blood-red flowers are produced in roundish drooping heads about 1 inch in diameter. It is rather difficult to grow, unless care be taken to layer the young procumbent growths in gritty soil. Given a well-drained position, and attention in the detail indicated, as well as a sufficiency of water when growing, there is no reason to despair of its cultivation. A remarkably handsome feature of the tall-growing "knotweeds" is the winter aspect of the graceful bamboo-like stems. Denuded of foliage, the lissom grace of the knotted stems is seen to the greatest advantage, while the warm, ruddy brown colour, which is developed mostly on the "sunny side" of the woody growths, adds not a little to the value of such species as P. cuspidatum and P. sachalinense.

Another plant which should be given a position where its roots may have access to an ample water supply is Romneya Coulteri. Until recently, the only position where experts considered it possible to grow and flower this plant was at the foot of a south wall. But now that we know of giant specimens growing entirely unprotected in the open ground (I heard of a plant recently in a Scottish garden which attains annually a height of 7 or 8 feet, and is rarely cut to the ground in severe weather), we may safely afford this noble Poppy-wort a more moist and a cooler position. The plant is a gross feeder. One specimen I know of has developed roots in the direction of a manure tank with unmistakable advantage, both to its general appearance and to the size and number of the flowers.

Correspondents in South Africa speak of acre after acre of marsh-land covered with species of Kniphofia, and dwell in glowing terms on the magnificent spectacle which is presented when the plants are in bloom. Is it not possible that we in this country could do better with the Torch-Lilies by affording them positions wherein ample supplies of moisture would be available? Of course, I know quite well the difficulty which is experienced in keeping these plants alive through the winter, particularly when newly planted, unless the position is well drained. There is the same difficulty in the case of Iris laevigata, but the best results are obtained in ground which can be flooded with water in summer, and I venture to think that similar treatment accorded to the Kniphofias would give results that would justify the attempt to reproduce natural conditions.

Lychnis chalcedonica is another plant which might be grown in moist positions with admirable results. Magnificent specimens, 4 feet high, with massive heads of the most brilliant scarlet flowers on erect stems clothed to the base with luxuriant foliage, present quite a different appearance from the starved specimens usually seen in borders of herbaceous plants destitute of foliage 1½ feet from the ground. In my opinion this is one of the best red-flowered perennials in cultivation, and I have found it respond to generous treatment in a way that, to me, was perfectly astonishing. Bright red is a somewhat rare colour by the water-side. Spiræa venusta, pink, in its best form, possesses plumes of a rich carmine-red colour, and attains a height of 6 feet in a moist position. The colour is more pleasing than that of Astilbe Davidii, another red-flowered plant which thrives in moist situations. I should very much welcome any information about a plant in cultivation under the name of Spiræa Humboldtii. It is a tall-growing herbaceous perennial, with a somewhat woody root-stock. Of robust habit, resembling S. Aruncus in general habit and S. lobata (venusta) more particularly in its inflorescence, the plant as grown here is quite distinct from either, and forms one of the most notable features on a July border. The chief distinguishing features may be cited as consisting of creamy-white flowers on white stalks, the lack of colour extending some little way down the rachis. Growing about 5 feet high, the graceful stems are clothed with elegant bipinnate foliage, the leaflets being more notable than in the case of most Spiræas for the sharply-pointed, almost spiny serrations. *E. Horton, Neston, Cheshire.*

——Whilst it is unquestionably a matter of opinion, I cannot but think the inclusion of such plants as Lychnis chalcedonica or any other garish border plant, in a water garden, is a step in the wrong direction. A water scene should be restful to the eye, and Lychnis chalcedonica will not contribute to this. The inclusion of well-known border-plants that can be well grown in their rightful places, particularly those of brilliant colouring and stiff habit, detracts from the interest a water garden should afford, by robbing it of its individuality. There are scores of plants, well fitted for waterside display, that cannot be well accommodated in a plant-border but which would lend interest to any description of water garden. What would your correspondent think of the artist who faithfully portrayed a water scene in all its many gradations of tone, light, and shade, and then, "just to give it colour," introduced a grouping of the most brilliant scarlet flowers, in massive heads, of Lychnis chalcedonica? Romneya Coulteri I have tried by the waterside; two years ago I planted six pot specimens in what I judged to be an ideal position—now there is but one sickly survivor. The Kniphofia described as an inhabitant of acres of marshland

in South Africa is the common K. aloides, according to many faithful correspondents—a plant that proves in this country to be the hardiest of its race; it grows well by the waterside, doubtless, but whether it is desirable to introduce such a tramp in a water scene is another matter of taste; there are several refined Kniphofias of hybrid origin that would contribute to an artistic *ensemble* by the waterside if grouped on the higher elevations. Mr. Horton has not quite grasped the purport of my article. I did not aim at supplying a list of plants that could be grown by the waterside, but of those that it was desirable to include in a water scene. More than half the border plants grown to-day would benefit by the moister conditions, but they would not constitute a water-garden even if planted by the waterside. *G. B. Mallett.*

POTATO TRIALS AT MESSRS. SUTTON'S, READING.

ON Friday, the 20th instant, by invitation of Mr. Arthur W. Sutton, a number of members of the Scientific Committee of the Royal Horticultural Society visited the trial grounds near Reading. The trials inspected were as follows:—

Trials on different soils of Solanum Commersoni, Solanum Commersoni Violet (Labergerie), and "Blue Giant" Potatos.

Comparative trials of several varieties growing from seed tubers harvested last season in the South of England, Lincolnshire, Scotland, and Ireland respectively.

Experiment to show effect of seed tubers fully and also partially matured.

Experiment to ascertain the result of planting tubers slightly affected with "Potato disease" (Phytophthora infestans).

Trials to show the comparative value of earthing up and growing on the flat.

Trials of "Up-to-Date" and varieties which to a greater or less degree resemble it.

Trials of "Abundance" and varieties possessing somewhat similar characteristics.

Rare species and wild types.

The above trials presented a number of extremely interesting features. Taking them in their order, a number of plants of Solanum Commersoni were exhibited in conjunction with M. Labergerie's assumed variety of the same species, and plants of the Blue Giant, a variety of the cultivated S. tuberosum. The species S. Commersoni is a small growing white-flowered species of stoloniferous growth, bearing somewhat heart-shaped berries and producing underground stolons, and small, very bitter, and quite uneatable tubers, in all ways different from S. tuberosum. Although sown by Messrs. Sutton for some 25 years, this species has never varied to any appreciable extent, and, despite innumerable attempts at cross fertilisation, only five seeds have been produced, and only one of these has produced a plant which is still young, and is presumably a hybrid. Berries, however, are fairly freely produced, but the seed proved abortive with the one exception cited. The reputed variety S. C. Violet not only differs entirely from its attributed parent, but closely resembles a known variety, Blue Giant, of German origin, that very little if any difference can be seen between them. Blue Giant has round berries, bluish flowers, is not stoloniferous has large blue edible tubers, and in all general respects ranks with the many forms of S. tuberosum or the common Potato of commerce. Blue Giant, furthermore, had been freely distributed for some years prior to the appearance of M. Labergerie's variety, and although the good faith of that gentleman is beyond question, the opinion of all the above-named gentlemen was unanimous that some mistake had occurred, and that probably by some accident a tuber of Blue Giant had been in the soil in which M. Labergerie had planted his tubers of S. Commersoni, and that this had led to a not unnatural misconception. The extremely close resemblance of the supposed sport with Blue Giant, and the very wide difference from S. Commersoni, in so many specific characters, flower, fruit, habit, foliage, tuber and stolon, constitute features such as are never seen in sports or mutations. All the characters of M. Labergerie's plant, in point of fact, are S. tuberosum characters, while all those peculiar to the asserted parent (Commersoni) are absent.

We may add, with reference to the statement that M. Labergerie's Potato is specially adapted to grow in wet places that Messrs. Sutton have specimen plants of Commersoni and of M. Labergerie's variety growing in or in immediate proximity to the moat surrounding the old manor house, but no differences were perceptible between these plants and those grown on drier soil.

The notion, therefore, that through S. Commersoni, any improvement in the disease-resisting qualities of commercial Potatos could be expected falls to the ground.

Prior to inspection of the above plants, a visit was made to a series of experimental beds designed to test the relative vigour and yield of Potatos, the seed tubers of which had been derived from the South of England, Lincolnshire, Scotland, and Ireland, a point of great agricultural importance, and in nearly every case it was clearly seen that tubers derived from sources where the climate was such that they ripened less perfectly produced much stronger haulm and heavier crops than those which came from southern and warmer sources, and were consequently thoroughly ripened. The evidence to this effect was extremely striking and conclusive, and it was stated by Mr. Sutton that, so far as was possible, the seed tubers obtained were from plants which had been acclimatised in their place of last origin for two years, one year hardly sufficing. A number of popular varieties were grown to demonstrate this principle, and the exceptions were too rare to vitiate the rule that it is advisable not to plant perfectly ripe seed tubers, but only partially matured ones.

Experimental rows showing the comparative value of earthing up and of growing on the flat showed practically no difference in the amount of haulm, and was regarded as the measure of the crop, which it was too early in the season to judge of otherwise. Other rows comparing the results of planting seed-tubers slightly affected with the Potato disease and sound ones showed, as might be expected, a material difference in favour of the latter, both in the extent of haulm and the absence of failures.

Time did not permit of inspecting the results of other trials, which were, moreover, of a minor nature, the main points being as detailed above.

The visitors partook of luncheon in the very ancient and half-ruined, moated, manor house, Southcote Manor, and were joined there by the Rev. Alan Cheales, of archæological renown, and of Rose-growing fame, who gave an interesting account of the mansion and its history.

[Further details relating to these Potatos are given in the report of the Scientific Committee. The differences observable between plants from M. Labergerie's tubers and those of Blue Giant are, if constant, so trifling as not to be recognisable on casual inspection, as the plants grow in rows side by side.—ED.]

ANATOMICAL CLASSIFICATION OF CERTAIN FERNS.—M. FERDINAND PELOURDE publishes, in a recent number of the *Comptes Rendus*, March 12, 1906, the outlines of a system according to which he would re-classify the species. He considers that the genera Asplenium, Polypodium, and Adiantum, are truly homogeneous. Asplenium shows close affinities with the genera Scolopendrium and Ceterach, and is as distinctly separate from the genus Athyrium as is the genus Polypodium from the genus Phegopteris. The genus Nephrodium is heterogeneous, and a division should be made so as to class Aspidium angulare with species of the former series. The genus Pteridium is distinct from the true Pteris.

SOCIETIES.

ROYAL HORTICULTURAL.

Scientific Committee.

JULY 17.—*Present*: Dr. M. T. Masters, F.R.S. (in the chair), Dr. M. C. Cooke, Sir John Llewelyn, Bart., Prof. G. Boulger, Messrs. A. W. Sutton, G. Massee, J. Douglas, W. C. Worsdell, and F. J. Chittenden (hon. sec.).

Remarkable Seedling Picotee.—Mr. DOUGLAS showed a curious plant raised from seed of a yellow ground Picotee crossed by pollen from a similar flower. The parents had long robust leaves, and were of the usual habit of the group, while the seedling had a very tufted habit, very much shorter and narrower linear leaves, much more glaucous than the parents, and small yellow semi-double flowers having slightly notched petals, the teeth being tinted red. The plant grew for three years before producing flowers, whereas one year is the usual period. There seems to have been no chance of cross breeding having occurred with another species.

Variation in Pinks.—Mr. DOUGLAS also showed an interesting group of flowers from Pinks grown from seed of the best varieties to demonstrate the exceeding variability in the flowers, both in the amount of doubling and the form and coloration. A considerable number revert to the single form.

Lateral Prolification in Carnations.—Mr. DOUGLAS also showed examples of a yellow Carnation in which the axis had branched at the base of the flower, producing a considerable number of lateral buds, a condition very frequently seen in Roses. A vote of thanks was unanimously accorded Mr. DOUGLAS for his interesting exhibits.

Malformation in Pea.—Mr. A. W. SUTTON showed a Pea plant where the flowers were abortive in a similar manner to those seen in the Bean shown at a recent meeting by Mr. DOUGLAS. This condition, which affected all the flowers on the plant, and on this plant only out of many thousands growing in a field, is said to be brought about by the presence of a species of gall-mite (Eriophyes).

Fasciation in Mangold.—Mr. SUTTON showed a remarkable specimen of this common phenomenon in a Mangold, where the flower-bearing stem measured nearly 2 inches in diameter.

Virescent Clover Heads.—Heads of Trifolium repens, in which some of the floral parts had been transformed into foliaceous leaves, were also shown by Mr. SUTTON. This well-known peculiarity has been shown to be due to the presence of an insect in the stem, probably Hylastinus obscurus, Marsh. (See M. Molliard in "Comptes Rendus," Nov., 1904, p. 930, and "Journal Royal Horticultural Society," vol. 29 (1904), p. 924.)

Tuberous Solanums.—Mr. SUTTON also showed a very interesting series of plants of tuber-bearing Solanums, together with water-colour drawings showing habit, &c.

1. Wild types of the following species raised from seed sown in March, 1906, and planted in the open in May.

(a) Solanum tuberosum, the true wild type now cultivated possibly for the first time in this country, raised from seed. The plants did not exceed 8 inches in height.

(b) Solanum verrucosum, about the same height as the preceding, but very different in habit.

(c) Solanum polyadenium (Greenman), collected in September, 1904. A very hairy species.

In all these three cases the specific types of Solanum have reproduced themselves absolutely true from seed without any variation whatever. This is the more remarkable because in no single case does the cultivated Potato of commerce come true from seed, and very seldom, if ever, does any individual seedling raised from a seed-berry (often containing two hundred seeds) from the cultivated Potato at all closely resemble its parent. The seedlings from the above three types are all equally true to the parent forms.

2. Specific forms of tuber-bearing Solanums raised from tubers, with illustrations of habit

(a) Solanum Maglia, as received about 20 years ago, and grown since then in Reading.

(b) Solanum etuberosum, as received about 20 years ago.

(c) Solanum, a type or species known as Papa d'amarilla, bearing a great resemblance to the type of S. tuberosum mentioned above. Mr. SUTTON had never known this variety to produce seed.

(d) Solanum Commersoni, the type as grown at Reading for several years.

3. Specimens of Blue Giant and of Mons. Labergerie's so-called Solanum Commersoni Violet variety.

(a) The Potato Blue Giant raised from tubers supplied by the raiser, Herr Paulsen, of Germany.

(b) The Blue Giant raised from tubers received from M. M. de Vilmorin of Verrières.

(c) Mons. Labergerie's so-called Solanum Commersoni Violet variety raised from tubers received direct from Mons. Labergerie's agent.

(d) Mons. Labergerie's so-called Solanum Commersoni Violet variety raised from tubers received from M. P. de Vilmorin of Verrières.

The last four specimens showed the extraordinary effect produced upon a crop of Potatos by the variation in soil or locality in which the tubers producing such a crop were grown.

The two specimens of Blue Giant and the two specimens of the alleged variety of Solanum Commersoni differed from each other much more than the specimens of Blue Giant differed from the Solanum Commersoni Violet variety of Labergerie grown in similar soil. Indeed, these two alleged different varieties were practically alike in appearance.

Malformation of Potato Flower.—Mr. SUTTON also showed an inflorescence of the Potato Up-to-Date, in which one of the flowers had the petals partially converted into stamens, the remaining flowers being normal. This inflorescence was taken from the plant which bore flowers all having a similar malformation shown by Mr. SUTTON before the committee on August 1, 1905.

Pisum sativum.—Mr. SUTTON also showed a specimen of Pisum sativum grown from seed collected by him from a plant growing semi-wild in a vineyard near Jaffa. The plant was about a foot high, had much serrated leaves and stipules, coloured flowers, and short curved pods. It had been crossed with the Duke of Albany Pea, and had produced a tall plant (which was also shown) somewhat intermediate in the foliage, having a dark coloured spot in the axil of the leaves, coloured flowers, and intermediate somewhat curved pods.

A hearty vote of thanks was accorded Mr. SUTTON for his numerous and interesting exhibits.

Colour in Sweet Pea Tendrils.—At a recent meeting Mr. CUTHBERTSON raised the question of the correlation of the red or green colour of the tendrils in certain varieties of Sweet Peas with other characters in the plant. He now sent specimens illustrating the possibility of the practical utility of attention to this character as an aid in "roguing" in the young stages of growth. A row of the Pea Captain of the Blues was carefully examined some time before flowering, and one plant that differed from all others in having green tendrils instead of red was marked. The flower of the normal Captain of the Blues has blue wings and a darker standard, while the marked plant was white marbled with blue all over. It is interesting to note that, as Mr. BATESON has previously pointed out, the red colour of the tendrils is usually correlated with a dark spot in the leaf axil, but in this variation the leaf axil possessed the dark spot which is found in all normal specimens of Captain of the Blues, although no trace of red colour was to be seen in the tendrils. Mr. BATESON has shown that the green tendril (light axil) character is a recessive one, and Mr. CHITTENDEN remarked that while in all the so-called sports of Countess Spencer which he had seen the tendrils were green, and the axils of the leaves devoid of the dark spot, Countess Spencer itself had red tendrils and dark-axilled leaves.

Flowering of Dasylirion glaucophyllum.—The following interesting note was sent by Lady THEODORA GUEST, of Inwood, Templecombe: "The Mexican Dasylirion glaucophyllum has thrown up an immense flower stalk in the conservatory here. It has grown some 16 feet in a fortnight, and is now covered with flower buds all up the stalk. A record is preserved of its flowering at Kew in 1857, when it attracted considerable attention, but Lady GUEST believes that the flowers have rarely been seen in England." The rate of growth recorded shows more than half an inch per hour maintained for a fortnight.

Axillary Prolification of Cornflower.—Dr. MASTERS showed a specimen of Centaurea Cyanus from Mr. W. G. SMITH, in which flower-bearing branches proceeded from the first-formed flower head somewhat in the manner seen in the Hen-and-chickens Daisy.

Diseased Peaches.—Specimens of Peach leaves attacked by the shot-like fungus Cercospora circumscissa, came from near Redhill, and shoots of Peaches showing brown spots at the base of the leaves and dropping their foliage as a result of the attack of the fungus Botrytis cinera on the imperfectly ripened wood. The only thing to be done is to cut out all diseased shoots and burn them, and then spray the trees with a rose-red solution of potassium permanganate.

NATIONAL CARNATION & PICOTEE (SOUTHERN SECTION).

JULY 24.—The Southern Section of this society held its exhibition at the Hall of the Royal Horticultural Society on the above date, the exhibits being fairly numerous and of fine average quality in the more important classes.

FIG. 32.—PICOTEE MR. NIGEL.

Many non-competitive groups of Carnations and Picotees were so many added attractions to the show, and gave a better idea of the beauty of the flowers and their effectiveness as decorative subjects than the stereotyped methods of the florists, and on these grounds justified their appearance on the tables.

The exhibits throughout were divided, as is now the recognised fashion, into dressed and undressed flowers, and the first we shall notice is the class for 18 Carnations, dressed on cards, bizarres, and flakes in not fewer than 12 varieties, and not more than two blooms of any one variety. Here the 1st prize was awarded to F. WELLESLEY, Esq., Westfield, Woking (gr. Mr. W. Hopkins). The stand consisted of the varieties Rt. Houlgrave, H. Shoesmith, Rt. Lord, G. Melville, A. G. Lewis, J. S. Hidderley, W. Skirving, Sportsman, Master Fred and George, the major portion, therefore, being old favourites; 2nd, MARTIN R. SMITH, Esq., Hayes (gr. Mr. C. Blick), with varieties that are modern, of which we may mention Gitana, Hotspur, Bonnie Jean, Butterfly, La Tosca, and Chas. Kean. A cursory glance would have placed this exhibit in the first position, but the florist would have detected here and there a spot on the ground colour, which turned the scale in the favour of the unblemished lot. Mr. C. TURNER, Royal Nurseries, Slough, was 3rd.

The best 18 self-coloured varieties were shown by the winner in the previous class, a very superior stand, the flowers of large size, smooth of petal, and regular in form. There were Daffodil, a beautiful clear yellow, Carabas, a variety that always taken a high place at shows, and that came out two years ago under the name of Lustre, Miss Willmott, Mrs. Eric Hamboro', W. H. Parton, Mrs. Flight, Nubian, Much the Miller, the fine rose-coloured Mrs. Guy Sebright and Isinglass; 2nd, MARTIN R. SMITH, Esq., with fine blooms of Comet, Imogene, Bonnie Dundee, Sir Galahad, &c.; 3rd, Mr. C. TURNER, with good Glowworm, Sir Bevys, Earl of Mercia, Jocelyn, &c.

The best 18 fancies were those shown by M. R. SMITH, Esq., the flowers unusually large, equal in size, and in the best condition. The stand contained Lord Steyne, Thais, Mandarin, Hidalgo, Highland Lass, Merlin, Hector, Douce Davie, a certificated variety, Bonnie Buchanan, and The Seer; 2nd, F. WELLESLEY, Esq., the stand including Liberté (new), R. A. Rowberry, &c.; 3rd, Mr. C. TURNER, in whose stand were nice blooms of Galilee, Emperor, Mrs. Tremayne, &c.

For 18 white-ground Picotees in not less than 12 varieties, F. WELLESLEY, Esq., won the 1st prize with the varieties W. E. Dickson, Mrs. Payne, Lavinia, Mrs. Gordon, Somerhill Aggie, Amy Robsart, &c.; 2nd, M. R. SMITH,

Esq., with noticeable blooms of Patty Oliver, White Lady Dolores, Siren, &c.; 3rd, Mr. C. TURNER.

F. WELLESLEY, Esq., had also the 1st prize for 18 Picotees, yellow ground, with exceedingly regularly-sized blooms, and totally free from blemishes. Childe Harold, Lord Napier, C. F. Thurstan, and Countess Strathmore were very nice blooms having wire edges. The best of the heavy edges were Miss Meredith Seedling, Gronow, Lucy Glitters, and Ida; 2nd M. R. SMITH, Esq., with fine blooms of Raphael, Nancy Oldfield, Goblin, and Dalkeith that was 1st of its class in 1901, and Ace of Trumps; 3rd, Mr. C. TURNER.

For six blooms of self Carnations F. WELLESLEY, Esq., was 1st with Eric Hamboro', MARTIN R. SMITH, Esq., 2nd with the same variety, and Mr. C. TURNER 3rd with Lady White.

For six blooms of any yellow or buff ground fancy Carnation:—1st, M. R. SMITH, Esq., with Mandarin; 2nd, F. WELLESLEY, Esq., with Miss Leese; and 3rd, Mr. T. TURNER, with Voltaire. For six blooms of any fancy Carnation, F. WELLESLEY, Esq., was awarded 2nd prize for Mrs. J. P. Barry.

UNDRESSED FLOWERS.

In the class for 18 self-coloured Carnations shown in bottles only the 2nd prize was awarded.

DRESSED FLOWERS.

The class for a stand of 12 Carnations, bizarres, and flakes was won by Messrs. PEMBERTON & SON, Bloxwick, with fine examples of R. Houlgrave, W. Skirving, G. Melville, Thalia, &c.; 2nd, Mr. H. R. TAYLOR, of Cheam.

For a stand of 12 self Carnations, not fewer than nine varieties, Mr. H. R. TAYLOR won the 1st prize with a faultless lot of blooms, of which the varieties W. H. Parton, Leslie Miles, a fine yellow of the tint of Daffodil, which was also observed in the exhibit, a bloom of Benbow, &c.; 2nd, Messrs. PHILLIPS & TAYLOR, Bracknell, who had fine blooms of Her Grace, Daffodil, Roy Morris, and Much the Miller.

The best 12 fancy Carnations were shown by Messrs. PHILLIPS & TAYLOR, the finer blooms being Bessy Barton, Mrs. Spencer, and Merlin; 2nd; M. H. R. TAYLOR, with Amphion, Monarch, King Solomon, &c.

The best 12 white-ground Picotees were shown by Messrs. PEMBERTON & SON, 1st, who had extra good examples of wire-edged varieties; 2nd Mr. H. R. TAYLOR.

Mr. H. MATHIAS was 1st for 12 yellow-ground varieties; 2nd, Mr. H. R. TAYLOR. Then came four classes for six blooms of Picotees, and self, yellow, or buff-ground fancy Carnations.

UNDRESSED FLOWERS.

For twelve self Carnations in not fewer than nine varieties:—1st, Messrs. PHILLIPS & TAYLOR; 2nd, Mr. H. R. TAYLOR. For twelve fancy Carnations and for twelve yellow-ground Picotees, the prizes were awarded to the same growers in the same order.

A number of small competitions followed in Carnations and Picotees of all classes.

CERTIFICATED VARIETIES.

These numbered four only, *viz.*, *Little Dick*, a crimson bizarre, shown by Mr. H. R. TAYLOR; *Æsop*, a yellow-ground Picotee, by Mr. H. MATHIAS; *Lady Gascoigne*, a yellow-ground Picotee, and fancy Carnation, *Doris Davis*, both from MARTIN SMITH, Esq.

THE NON-COMPETITIVE GROUPS

were numerous, M. R. SMITH, Esq., showing a large exhibit mostly of newer varieties; Messrs. T. WARE, Ltd., had a number of plants of the scarlet self tree Carnation, Lottie Pike, and other varieties; Miss SHIFFNER, Woodland House, Lewes, had blooms of a yellow self, named King Henry. A large group of Malmaison Carnation plants was contributed by Messrs. CUTBUSH & SON, Highgate, containing several fine varieties of this and other sections; Mr. A. DUTTON, Iver, Bucks, had an extremely fine show of cut blooms of Carnations; Mr. H. MATHIAS, of Medstead, Surrey, showed Picotees and Carnations; Mr. J. DOUGLAS, Edenside, Great Bookham, had a very fine display in glasses of choice varieties of Carnations and Picotees.

Groups of hardy herbaceous perennials were shown by Messrs. R. SMITH & Co., Worcester, who included, likewise, many pictorial shrubs and trees; by Messrs. BARR & SONS, King Street, Covent Garden; Misses HOPKINS, The Mere, Knutsford, showed cut blooms of hardy flowers; Mr. LAKEMAN, Thornton Heath, showed a group of Carnation plants, the effect being spoiled by thick stakes.

FIG. 33.—PICOTEES GRONOW AND AMPHION.

M. R. SMITH, Esq., won the 1st prize for 18 fancy Carnations with Hidalgo, Flamingo, Erl King (new), Pasquin, The Seer, Infanta, Jeremy Solon, &c.

The class for 18 yellow-ground Picotees was not well filled:—1st, M. R. SMITH, Esq.

The next four classes were small ones, calling for no comment, and the champions in the previously-mentioned class were contestants in these likewise.

MARTIN R. SMITH, Esq., won the 1st prize for 12 distinct varieties selfs, fancies, and yellow-ground Picotees

NEWPORT HORTICULTURAL.

JULY 19.—This Monmouthshire society held its annual show in the King's Hill Field, Newport. The exhibits were generally very creditable productions, and occupied four large tents, though the groups of plants and specimen plants usually staged here by Messrs. CYPHER, of Cheltenham, were absent. It may be remarked that the committee might have made the show more instructive if they had insisted upon all the exhibits in reasonable instances being properly named.

GROUPS OF PLANTS.

A class for plants arranged in a space of 100 square feet brought two excellent collections. Mr. Powell (gr. to Col. C. T. WALLACE) won the 1st prize with a bright, graceful, though somewhat crowded group, composed chiefly of Orchids, Lilium speciosum, Francoa, Campanulas, Gloxinias, Palms, Eulalia, Humea, and Ferns. Mr. F. Wood (gr. to H. OAKLEY, Esq., Dewstow) was 2nd. For a smaller group Mr. J. Wiggins (gr. to R. J. MANN, Esq.) secured the leading prize.

Gloxinias in groups of 25 square feet were shown by R. P. WILLIAMS, Esq., and H. LE BRASSEUR, Esq., who were awarded equal 1st prizes.

There were Tuberous Begonias in similar groups from four exhibitors. The best came from Mr. J. Pegler (gr. to M. MORDEY, Esq.), who had splendid plants of large-flowered varieties.

For six stove and greenhouse plants in flower Col. WALLACE was placed 1st, with medium-sized, well-blossomed plants of Clerodendron Balfouri, Allamanda nobilis, A. Hendersoni, Rondeletia speciosa, Acalypha hispida. He also won the Society's Silver Medal offered for the best flowering plant in the show with the Clerodendron. G. F. COLBURN, Esq., was 2nd.

The best group of six Ornamental Foliage Plants was shown by Mr. Duff (gr. to Mrs. WILLIAMS, Bryngias, Newport).

Col. WALLACE won 1st prizes for six Exotic Ferns, six Caladiums, and for six pans of Achimenes.

Coleus were staged best by Mr. Wheatland (gr. to Mrs. J. LINTON), and Tuberous Begonias by Mr. PEGLER. Gloxinias in six varieties were splendidly staged by Mr. E. Vivian (gr. to A. S. MORGAN, Esq.).

The class for six table plants in 6-inch pots tempted exhibitors, and Mr. J. H. Pullen (gr. to G. R. MARTYN, Esq.) won the 1st prize.

Col. WALLACE had the best collection of 12 decorative plants, including six ornamental-leaved sorts and six in flower.

Mr. STEPHEN TRESEDER, The Nurseries, Cardiff, was the only exhibitor in the classes for 24 Rose blooms and 12 blooms, and staged excellent flowers.

The best hardy flowers were shown by Messrs. H. C. W. EVANS, of Llanishen, and C. H. EPSWORTH, Esq. (gr. Mr. German) was the most successful exhibitor of Sweet Peas.

Mr. A. W. MORRIS, Penarth, won the 1st prize for 12 Carnations.

Collections of fruit and single dishes of Grapes, Peaches, Nectarines, Melons, &c., were well shown, the chief exhibitors being Mr. DUFF, Mr. Long (gr. to W. T. DAWSON, Esq.), and Mr. WOOD. Vegetables were also shown in large quantities, and of excellent quality; Messrs. SUTTON & SONS, CARTER & Co., GARAWAY & Co., CLIBRANS, and J. C. WHEELER & SONS offered valuable special prizes.

TRADE EXHIBITS.

A Gold Medal was awarded to Messrs. HEATH and SON, Cheltenham, for Roses, Carnations, Sweet Peas, and Herbaceous flowers, and Silver Medals to THE KING'S ACRE NURSERY Co., Hereford, for Roses; to Messrs. TUPIN & SONS, Newton Abbot, for Carnations, Zonal Pelargoniums, &c.; and to Messrs. A. M. HARDING, florists, Newport, for Floral designs, bouquets, &c.

MANCHESTER & NORTH OF ENGLAND ORCHID.

JULY 12. *Present*: E. Ashworth, Esq., in the chair; Messrs. Cypher, Ashton, Williamson, Upjohn, Rogers, Shill, Loemann, Keeling, Cowan, Ward, Thorp, R. Ashworth, Ritchie, Parker, Stevens, P. Smith, and Weathers (hon. sec.).

W. THOMPSON, Esq., Stone (gr. Mr. Stevens), was awarded a gold medal for a fine group of plants consisting principally of Odontoglossums, and staged alongside of this group was a fine collection of well-grown plants of Cochlioda Nötzliana, bearing a profusion of their scarlet blossoms, which was voted a Cultural Certificate. Cypripedium × Daisy Barclay, a good hybrid between C. leucochilum and × C. Rothschildianum was awarded a First Class Certificate, as was also C. leucochilum var. Hodgkinsoni. C. × "Sheila," a cross between C. Harrisianum var. superba and C. × triumphans, from the same exhibitor, was voted an Award of Merit.

J. CHARLTON PARR, Esq., Grappenhall Heys, near Warrington (gr. Mr. Masterton), exhibited a good collection of Disa grandiflora; the plants were remarkably well grown. A Cultural Certificate and special vote of thanks were awarded.

R. ASHWORTH, Esq., Newchurch (gr. Mr. Pidsley), obtained a Bronze Medal for a group which included the new hybrid Odontoglossum × Ashlandense, a cross between O. polyxanthum and a variety of O. × Adrianæ. Cypripedium × "Britannia" was also shown.

Dr. A. HODGKINSON, Wilmslow (gr. Mr. Woore), obtained a First-Class Certificate for Cypripedium leucochilum var Hodgkinsonæ, and C. niveum, "Grange variety."

PHILIP SMITH, Esq., Ashton-on-Mersey (gr. Mr. Kitchin) obtained a Bronze Medal for a miscellaneous group, the best thing in which was a bright form of Cattleya × Hardyana, "Haddon House variety."

E. ASHWORTH, Esq., Wilmslow (gr. Mr. Holbrook), obtained an Award of Merit for Dendrobium × Leeanum, and Cattleya Mendeli, var. "Oakes Ames."

Messrs. H. LOW & Co., Enfield, exhibited Cattleya Gaskelliana, var. alba, for which they received an Award of Merit.

Mrs. S. WOOD, Glossop (gr. Mr. Gould), exhibited a good collection of plants, in which were some hybrid Cattleyas. (Bronze Medal.)

MAX ISAAC, Esq., Liverpool, exhibited a good plant of Lælio-Cattleya × callistoglossa. Vote of thanks.) *P. W.*

PLANT NOTES.

EUSTOMA RUSSELLIANUM.

THE sight of this beautiful plant at the Holland House Show and the following week at Vincent Square Hall (see fig. 26, p. 55), will perhaps induce gardeners more to undertake its culture. There is scarcely another plant of its colour that is at once and the same time so refined in habit, and distinct in the colour and form of its flowers. The plant lasts for several weeks in bloom if afforded cool treatment, shade from the mid-day sun, and afforded plenty of water; in fact, during very dry weather it may be stood in a saucer of water without injury. It is an annual, but does best if treated as a biennial; seeds being sown in sandy peat and leaf mould in August, or the seed may be germinated on a thin layer of soil laid on a porous red brick or tile, in a vessel of water so as to avoid the necessity of applying water overhead. The plant requires a very moist medium, and the seeds being of extreme fineness they may be readily washed out of the soil and lost by using the watering pot. Little artificial heat is required by the plant at any period of its existence, only a cold frame or pit from April to October, and a greenhouse during the remaining months of the year. It is advisable to sow the seeds at the time named above late in the month in the south and earlier in the north, so as to possess plants about 3 inches high at the commencement of winter. The seedlings must be pricked off as soon as they can be handled, much root disturbance being harmful at any stage of growth. I have had the best results from pricking out into thimbles, say two plants to each, afterwards throwing away the weaker one. In the ordinary case two shifts should be afforded, the second one early in October, which should be into a small 48, and preferable a bulb pot, a small quantity of good loam being added to the peat and leaf mould. The plants should occupy a shelf close to the glass, be afforded water with great care, and only when water is necessary, too much or too little being alike fatal to the plant. A keen outlook must be kept for aphis attacks, to which the plant is very liable, the fumigator being brought into use as soon as any aphides are observed. When new growth is apparent, say in March or April, the plants should be shifted into pots not less than 8 inches in diameter, unless very early bloom is required, when 6-inch pots are to be preferred. If the plants are intended for the larger sized pot, the point of the stem should be nipped off a week or two before the repotting is carried out. This stopping once gives an increase to the number of branches or side shoots, which, when tied outwards, make a plant 15 to 18 inches in diameter, and as each carries a number of blooms, the floral display is all the greater. *F. M.*

KEW NOTES.

LARKSPURS.

THE double-flowered forms of the common Larkspur, Delphinium ajacis, are amongst the most beautiful hardy annuals, and the earliest of the annual Delphiniums to flower. The dwarf German Rocket (Hyacinth-flowered) varieties are especially good. A feature of the Range Terrace for fully two months has been four large and two small beds, each devoted to a separate colour or shade of colour. The dense spikes are very showy. The seeds can be bought in mixed colours, or in separate packets of at least a dozen shades of colour: white, apple-blossom, buff, rose, brick-red, lilac, fawn, and several shades of blue. The seeds may be sown in autumn or spring, preferably in the beds or borders where they are to flower. Thin out the seedling when large enough, leaving them about 12 inches apart. The plants average 18 inches to 2 feet in height. They require much moisture at the roots. The present season has been rather dry for them in the London district. *D. D.*

CÆSALPINIA GILLIESII.

A FINE specimen of this very handsome leguminous shrub is flowering on the front of Museum No. 1. It is about 20 feet in height. A number of the growths near the top are carrying terminal racemes, each bearing from 30 to 40 rich yellow flowers, which have very conspicuous scarlet stamens, about three times the length of the corolla. If a position on a south or south-west wall can be given it, the plant will need little or no protection. The points of the plant at Kew are occasionally cut back by early autumn frosts, but this occasions very little harm. In the warmer parts of the country, notably Devonshire and Cornwall, it succeeds in the open. A good figure was published in the *Botanical Magazine*, tab. 4,006, under the name of Poinciana Gilliesii.

MARKET GARDENING.

BROAD BEANS.

THE general or consuming public seem to know little of the distinctions gardeners and seedsmen make in what are commonly known as "Broad" Beans. Possibly that ignorance is due to the undoubted fact that the Long Pod section seldom find their way into market for public sale. Market growers, so far as they grow Beans, seem to keep to the old Windsor type as the only one likely to suit customers, and it may perhaps largely be due to that, as also to the practice of gathering these Beans for market when they are somewhat old and the skins tough, that there is now only a very limited demand for them. Perhaps, too, with the increase of edible Green Pea varieties, enabling the ordinary consumer to have that delectable vegetable whilst young and fresh, at moderate prices, the old taste for Broad Beans has been obliterated. Certainly really good Marrow Peas can now be had almost anywhere in their season cheap and good. But it is a strange fact that whilst market growers seem thus to ignore Long Pod Beans, cottagers in every direction grow them largely and well. Since the introduction of the Seville type of Long Pod many years since, with its very long, although badly filled, pods, and those but sparsely produced, there has been effected remarkable improvement. On every hand we now see varieties of such excellence that not only do they crop abundantly, but the pods, almost longer than ever, are cramfull of beans; hence, as crops, the newer varieties are some of the most profitable it is possible to grow. I have of late seen in numerous cottage gardens and allotments, and, doubtless, many others have, abundant crops of very fine long pods borne on clean, robust, and healthy plants. A remarkable feature, having regard to the comparative dryness of the season, has been the rare occurrence of black aphis, and this on all sorts of soils. It is thus evident that, if in cottage gardens and on allotments Long Pod Beans can be grown so well, they can be equally well grown on a large scale in fields. Cottagers are, apart from their liking for these Beans, much encouraged to grow them by the prizes offered at the myriad of local cottage-garden shows held in the kingdom. Now and then there is a class for Old Broad Windsor. At Colchester, for instance, one gentleman gives special prizes for Windsors only of the true broad type, although the exhibits in that class make a poor display when compared with the fine, long, handsome pods in the Long Pod class. Broad Windsor pods carry two and, sometimes in an exceptionally good stock, three Beans in a pod, whilst the best of the Long Pods have seven equally fine Beans in each pod. These long pods are produced on plants quite as freely as are the shorter Windsors. Hence it is seen that as a matter of profit the latter are far more worthy of encouragement. There are many names to the Long Pod stock, though not greatly differing in character; Minster Giant, Leviathan, Exhibition, Mammoth, Prolific, and other appellations are listed. Probably one of the very best is the Giant Green Long Pod, because of the deep green colour of the Beans and their high flavour.

Beans for competition must be long, straight, fresh, well-filled, and all selected for a "dish," and must present an even appearance. When some 20 or more dishes, all very good, are staged in a class, judges have a difficult task before them to determine which is best. Seeing how popular this type of Bean is with the working classes, market growers perhaps might do worse, especially where they have stiff soils to grow them largely, and market the pods ere too old in bundles of, say, 25, selling the pods in that way by number rather than by measure or weight. The experiment should be worthy a trial. *A. D.*

FOREIGN CORRESPONDENCE.

GLADIOLUS.

For a long period I have grown, year by year, a quantity of Gladiolus—seedlings. The seeds are sown about the beginning of May in cold frames, and the bulbs lifted in autumn and planted the following year in the open ground, &c. Several years ago I noticed a plant that began to bloom in the seed bed, but the flower spike was killed by frost before it came to full development. I selected the bulb, planted it separately, and crossed the flowers with my best flowering sorts. I selected seeds from this cross carefully, and sowed them the following year about the middle of March. Several of these seedlings began to bloom about the end of August, and I obtained some ripe seeds of the plants. Last year the first flower opened on July 23, but this year the first flower has opened on July 12. By crossing and selecting the very best and most perfect seedling plants and seeds of these, also by new crossings with pollen of the different types of Gladioli, I have in my annual type of Gladioli not only a rich collection of colours, but also all the different types of Gladioli; also last year I noticed some plants with very widely-opened flowers similar to those of Amaryllis. The beds show a continuance of blooming from July until very late in the season; the last flowers were killed by frost. On many of the flower spikes are opened five to six flowers at once. The colours vary from white to yellow, flesh, rose and pink, bright red, cherry red, blood red to maroon and brownish red, &c. Last year I noticed a few with light and deep blue flowers. The individual flowers are of good size and form. *Frederick Roemer, Quedlinburg, Germany.*

THE WEATHER.

THE FOLLOWING SUMMARY RECORD of the weather throughout the British Islands, for the week ending July 21, is furnished from the Meteorological Office:—

GENERAL OBSERVATIONS

The *weather* was mostly fair to very fine in the central, southern, and western districts, and occasionally very fine in the north and north-west also, but scarcely a day passed without measurable amounts of rain in many parts of the latter regions. Local sea fogs were experienced on our south-western coasts during the earlier days of the week. Distant thunder was heard at Swarraton on Thursday.

The *temperature* was below the average generally, but above it in England N.E. and Ireland S. The highest of the maxima occurred on Wednesday in most districts; in England E. the thermometer rose to 82°, in England S. to 81°, and in the Midland Counties to 79°. In Ireland N. and Scotland N. the respective maxima were only 69° and 66°. The lowest of the minima were recorded, as a rule, late in the week and ranged from 39° in England S. and 40 in England E. and Scotland W. to 46° in Ireland S., and to 51° in the Channel Islands.

The *rainfall* was greatly in excess of the average in Scotland N. and considerably in excess in Scotland W.; in all other districts there was a deficit, the fall in England N.E. and the Midland Counties being particularly slight. On Tuesday and Wednesday an exceedingly heavy fall of rain occurred in the north-west of Scotland, the aggregate amount for the two days being as much as 4·9 inches at Fort William and 4·4 inches at Glencarron.

The *bright sunshine* was very deficient in the Channel Islands and England S.W. and slightly in England S., Ireland S., and Scotland N., elsewhere there was an excess. The percentage of the possible duration ranged from 47 in England N.E., 43 in England E., and 40 in the Midland Counties, to 27 in Ireland S., 24 in the Channel Islands, and 21 in Scotland N.

The *barometer* and *wind*.—During the whole of the week pressure was highest to the southward of the United Kingdom and low over the north-eastern parts of the Atlantic. Several shallow depressions passed eastwards across the northern districts of our Islands without having much influence on the force of the South-westerly and Westerly winds. The only serious disturbance was one whose centre lay near the Shetlands on Thursday morning. This was very deep for the time of year and caused fresh or strong Westerly gales on the northern coasts of Ireland and Scotland.

THE WEATHER IN WEST HERTS.

Dry and variable in temperature.—The first three days of the week were rather cool, but since then the weather has remained warm during the daytime, and on the warmest day the temperature in the thermometer screen rose to 79 degrees. On the other hand on two nights the exposed thermometer fell respectively to within six and three degrees of the freezing point, the latter a very low reading for the time of year. The ground is now about one degree warmer than is seasonable, both at one and two feet deep, and at the latter depth it is rather warmer than at any time this summer. No rain worth mentioning has fallen for a fortnight, and for a rather longer period there has been no measurable percolation through the bare soil gauge. The sun shone on an average during the week for seven hours a day, or for three-quarters of an hour a day longer than is usual at this season. Light airs have alone prevailed, while the direction of the wind has been almost exclusively some westerly point of the compass. The mean amount of moisture in the air at 3 p.m. fell short of a seasonable quantity for that hour by 6 per cent.—*E. M., Berkhamsted, July 25, 1906.*

MARKETS.

COVENT GARDEN, July 25.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday, by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate, not only from day to day, but occasionally several times in one day.—ED.]

REMARKS.—English Peaches and Nectarines are cheaper owing chiefly to the large quantities that are now arriving daily. English Tomatos are cheaper and likely to continue so the whole week. Soft fruit is very plentiful. Trade generally is good. *A. H. Rides, Covent Garden, July 25, 1906.*

POTATOS.

Lincolns, 70s. to 85s.; Bedfords, 65s. to 75s.; Kents, 55s. to 100s. *John Bath, 32 and 34, Wellington Street, Covent Garden.*

COVENT GARDEN FLOWER MARKET.

Although growers complain of bad trade, I find there is a good many plants going out of the market, though prices are low except for anything specially good. Large quantities of Fuchsias were sold this morning at 2s. to 2s. 6d. per dozen, but they would not have been good enough for the florists' trade. Verbenas, being very plentiful, realise only very low prices. It is difficult to give even approximate prices for plants just now, for many are anxious to clear out and finish up for the season. Growers say that it is owing to the cold spell we had late in the spring that they are later than usual this season. Pelargoniums are not quite so plentiful, but there are still some good plants to be seen. Zonal varieties are very good in white, scarlet, and salmon,

of the latter, Mrs. Lawrence is good, but King of Denmark is still the best. Double and single Petunias are good. Campanula isophylla alba varies, but there are some well-grown plants, as there are also of C. × Mayi. Hydrangeas hold out, but there is now little trade for them. Some fine Crimson Rambler Roses were in this morning, also plants of Dorothy Perkins; prices for these are lower now. Some well flowered plants of Lantanas make from 6s. to 9s. per dozen in 48 size pots, and some larger plants have been making 2s. 6d. each. Liliums include L. auratum, L. longiflorum rubrum and L. l. album. Marguerites continue to be plentiful and good, also Chrysanthemum segetum, Heliotropes and Coreopsis. Crassulas are now nearly over for the season. In foliage plants, Coleus and Kochia scoparia are plentiful. I hear from one grower that the seed he bought for K. scoparia proved to be a different plant to what we have known under this name, and quite worthless, but he got the right plant under the name K. trichophila.

CUT FLOWERS.

Heaps of flowers are now wasted, it is impossible to sell them at any price; the supplies of Sweet Peas, for instance, are far in excess of all demands. It is much the same with Carnations; small blooms were offered at 1s. to 1s. 6d. per dozen bunches, and quite good blooms were offered at 6d. per bunch of 12 blooms, but best Americans may make better prices. Roses are equally plentiful; nice blooms of Perle du Jardin were offered at the close of the market at 4d. per dozen or even less, and other sorts at proportionately low prices. Best Lily of the Valley is not abundant, but small blooms are cheap. Outside the market the blooms were offered at 2/1 per bunch this morning. Gladiolus Brenchleyensis and G. The Bride are very good. Montbretia crocosmæflora and Liliums continue plentiful. In hardy flowers Gaillardias, Coreopsis grandiflora, Gypsophila, Statice, Asters, &c., are over abundant. Lavender being now on the market, many of the hawkers give their attention to this instead of to ordinary flowers.

GARDENERS' DEBATING SOCIETIES.

DEVON AND EXETER GARDENERS'.—The fifteenth annual outing of this society took place on the 11th inst., when members and friends, to the number of 115, journeyed to Weston-super-Mare. A special steamer was chartered to carry the party to Mumbles Head for Swansea. After a short stay on the breezy promontory, the party proceeded to the grounds of Singleton Abbey, the seat of Lord Swansea, and were conducted round the gardens by Mr. Treblle, the head gardener, and others. Two particularly fine specimens of Sikkim Rhododendrons, R. Falconeri and R. barbatum, were noticed, the former being fully 20 feet in height, while the latter was nearer 30 feet in height. Many fine and well-trained Camellias were noticed in the avenue. The great market and other interesting features of the town were also visited. It was intended to visit Clyne Castle, but a delay owing to the steamer being late prevented this being done. *A. H.*

CROYDON AND DISTRICT GARDENERS'.—On the 18th inst., about 30 members of this society journeyed to Gatton Park, Reigate, the residence of Mr. Jeremiah Colman. Mr. W. P. Bound and his excellent staff of gardeners did everything they could to make the visit enjoyable. The first thing noticed on entering the park was a fine Elm avenue, known by tradition as bordering the Pilgrim's Way. A visit was paid to the Gatton Town Hall, situated in the park, and this in itself is a great attraction. The gardens were the chief attraction. Orchids are seen here in a superb collection. Seedling hybrids of Orchids are counted by the thousand. In the kitchen garden there is a giant trained specimen of Uvedale's St. Germain Pear measuring something like 90 feet from tip to tip.

GARDENING APPOINTMENTS.

MR. F. G. FREEMAN, for the past three years Foreman in the Gardens, Southgate House, and previously three years Foreman at Blackdown House, Haslemere, as Gardener to E. M. BRISTOWE, Esq., Great Baddow House, Chelmsford.

MR. W. W. SIMPSON, for the past 19 years Gardener to the late JOHN MERCER, Alston Hall, Grimsargh, Preston, as Gardener to Mrs. CROOK, Stanley Grange, Hoghton, Preston, Lancashire

MR. J. ELWORTHY, for the past 11 years Gardener to J. W. SMITH, Esq., J.P., Ivy House, North End, Hampstead, as Gardener and Bailiff to the same gentleman at Sparrow's Herne Hall, Bushey Heath, Watford, Herts.

CATALOGUES RECEIVED.

ENGLISH.

CLIBRANS, Altrincham and Manchester—Strawberries.

JAMES DOUGLAS, Edenside, Great Bookham, Surrey—Carnations, Picotees, Auriculas, Daffodils, &c.

CARTER PAGE & Co., 52 and 53, London Wall, London, E.C.—Dahlias.

F. C. EDWARDS, Warehouse Hill, Leeds.—Bulbs.

HERD BROS., Penrith—Bulbs.

SCHEDULE RECEIVED.

Prize List of the 3rd Joint Annual Agri-Horticultural Show of the STRAITS SETTLEMENT AND FEDERATED MALAY STATES to be held in the Raffles Reclamation Ground, Singapore, on Thursday, Friday and Saturday, August 16, 17 and 18, 1906

PLANT PORTRAITS.

LYCORIS INCARNATA AND L. SPRENGERI.—*Garden Week*, July 7.

ZANTEDESCHIA REHMANNI COCCINEA.—*Gardening World*, July 1.

ENQUIRIES AND REPLIES.

GOOSEBERRY MAY DUKE.—Can any reader tell me who raised this variety, and by what firm it was first distributed? *L. N., Germany.*

PRESERVATION OF APPLES.—Would it be possible with any degree of success to keep Apples in the same manner as recommended for Potatos in your last issue? *Somerset.*

ANSWERS TO CORRESPONDENTS.

*** EDITOR AND PUBLISHER.—Our Correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the PUBLISHER; and that all communications intended for publication, or referring to the Literary department, and all plants to be named, should be directed to the EDITOR. The two departments, Publishing and Editorial, are quite distinct, and much unnecessary delay and confusion arise when letters are misdirected.

BASIC SLAG ON LAWNS: *D. B.* Basic slag is especially noted for its encouragement of Clovers both on lawns and in permanent pastures. It would be advisable in your case to apply a dressing of sulphate of ammonia, 3 ounces per square yard, mixed with a little leaf-mould to facilitate even distribution. This may be put on at once, and if rain does not follow quickly, afford the lawn a copious watering with the garden-hose. The ammonia will obliterate the Clovers and encourage the Grasses. It will also destroy Moss. During the winter give a fair coating of leaf-mould, with which may be mixed some dried and finely-sifted fowl manure. A further dressing of sulphate of ammonia in the same proportions may be given in the month of March next year. An occasional watering of soot-water (water in which a bag of soot has been suspended) will greatly tend to keep the lawn green.

CUCUMBER ROOTS: *J. E. R. N.* The plants are badly infested with Eel-worm, which being so minute are invisible to the unaided eye. There is no cure for this pest, and the only advice we can give you is that for the next crop it will be necessary to adopt preventive measures. Every particle of the old soil should be taken away and sterilised by burning. The interior of the house should be thoroughly cleansed with a strong disinfectant or insecticide. When this has been done, endeavour to procure fresh soil from a source you have reason to believe is free from this pest, or if you cannot do this, then sterilise the soil by baking or steaming it before it is conveyed into the house.

IRIS: *W. L., Finchley.* The Iris is attacked by the well-known bacterial rot. Cut away all diseased portions and soak the healthy parts for half an hour in Bordeaux mixture before planting. As the soil in which the plants have been grown will be affected, it should be replaced by fresh soil, or better, the plants should be removed to a new locality. The infected soil should be sterilised with lime or kainit.

NAMES OF FRUIT. *J. W.* The Japanese Wineberry, Rubus phœnicolasius.

NAMES OF PLANTS: *J. T. S.* Pisum arvense (Field Pea).—*W. H. D.* Mentha Requienii.—*J. W., Cardiff.* 1, Malva crispa; 2, M. sylvestris var.; 3, Impatiens scabrida; 4, Dianthus arenarius; 5 and 6, Campanula rapunculoides; 7, Œnothera sinuata; 8 and 9, Linaria hybrids, impossible to name; 10 and 11, Eucharidium concinnum; 12, Aquilegia chrysantha var.; 13, A. Jaeschkani.—*J. W.* Picea ajanensis; 2, Lonicera alpressa, Silver Milkmaid Holly; 3, Ilex aquifolium argenteo medio picta; 4, Quercus imbricaria.—*Without name or number.* The tree is Cornus mas variegata; Sempervivum sp.; Antirrhinum; Galega; Delphinium. We can do no better for you in the circumstances.—*C. H. B.* Salvia Horminum, an herbaceous perennial plant.—*Sprenger.* Xysmalobium undulatum, Rhodesia.—*E. Rose.* Æschynanthus Lobbianus. The excrescences on the Eranthemum leaf appear to have come from the leaf itself, provoked either by the punctures of insects or by uncongenial atmospheric influences.—*W. M. A.* 1, Buddleia globosa; 2, Clematis Flammula.—*W.* 1, Crucianella stylosa; 2, Fabiana imbricata; 3, Eccremocarpus scaber.—*L. C.* 1, next week; 2, Rubus micranthus; 3, leaves only perhaps Saponaria officinalis; 4, next week; 5, Campanula rapunculoides; 6, Staphylea pinnata.—*W. B., Notts.* Why pack in the worst substance you can find—cotton wool? Your plant is the Summer Savory, Satureia hortensis.—*H. R. G.* 1, Veronica spicata white; 2, Erigeron speciosus; 3, Hibiscus syriacus; 4, Spiræa filipendula; 5, Aconitum variegatum; 6, Gnaphalum margaritaceum.—*T. H. B., Powderham.* 1, Pinus excelsa; 2, Sciadopitys verticillata; 3, Abies cephalonica; 4, Tsuga Brunoniana; 5, Abies brachyphylla; 6, Pseudotsuga Douglasii; 7, Abies magnifica; 8, Abies concolor; 9, Spiræa ariæfolia. Thank you for sending such satisfactory specimens.

NECTARINE FRUITS: *A. C.* Gumming is caused by a fungus called Coryneum Beyerinckii. This fungus winters on dead shoots and spurs, from whence the spores are washed on to the surface of the young fruit. All diseased portions of the tree should be cut off and burned.

PEA HAULM: *S. W. E.* The Peas have been injured by the Pea thrips (Thrips pisivora). The Peas and Pea-rods should be burned and the ground should be well limed. It is not safe to grow Peas or Beans on land that has borne a diseased crop in the previous season.

POTATOS FOR CERTIFICATE: *Murphy.* You should show the tubers to the Fruit and Vegetable Committee of the Royal Horticultural Society, and to the judges at the National Potato Society's show, which will take place in the autumn. The R.H.S. meetings are held fortnightly—that you may write to the secretaries we append their addresses: Secretary, Royal Horticultural Society, Vincent Square, Westminster, and Mr. W. H. Adsett, Halton House, Great Queen Street, W.C.

SOLANUM LEAVES: *W. C. L.* What you see on the under side of the leaves is not the result of insects or of fungous disease, but is analogous to the out-growths from Vine leaves, being generally the result of uncongenial atmospheric influences.

STRAWBERRY PLANT: *J. F.* The plants are badly attacked by the Strawberry leaf spot (Sphaerella fragariæ). The most effective cure is to cut off all the leaves a little later in the season and allow them to lie on the ground until fairly dry, then scatter a thin layer of straw over the bed and set fire to it. By this method all diseased leaves, also all spores lying on the ground, are destroyed and the plants will break into growth again vigorously and free from disease. Next spring spray the young leaves two or three times at intervals of a fortnight with a solution of potassium sulphide—1 ounce to 3 gallons of water.

VIOLAS: *C. A. B.* There is no specific disease present that can be attributed to either fungi or insects. The particular variety of Viola appears to be rather difficult to manage everywhere, and will not bear as much water as other kinds.—*H. A. S.* Botrytis vulgaris, a parasitic fungus, is the cause of the mischief, and its presence suggests too much moisture in the soil. Open out the plants and admit air to the surface of the soil. Water with a solution of permanganate of potash (= Condy's fluid) diluted to a pale-rose colour.

THE PROGRESS OF GENETIC RESEARCH.*

IT is just eight years since, on the hottest day of a very hot summer, the first Conference devoted to Hybridisation and Plant Breeding assembled at Chiswick. Looking back on that occasion we realise, what some of us even then suspected, that we were concerned in a remarkable enterprise. No such conference had taken place before, and our proceedings were of the nature of experiment. That definite results might come from that beginning we naturally hoped, but of those who endured the heat of that stifling marquee or inspected the plants exhibited in that tropical vinery, not one, I suppose, anticipated that in less than a decade we should have such extraordinary progress to record. The predominant note of our deliberations in 1898 was mystery. In 1906 we speak less of mystery than of order.

When formerly we looked at a series of plants produced by hybridisation we perceived little but bewildering complexity. We knew well enough that behind that complexity order and system must be concealed. Glimpses, indeed, of pervading order were from time to time obtained, but they were transient and uncertain. As casual prospectors we picked up occasional stray nuggets in the sand, but we had not located the reef, nor had we any machinery for working it if discovered.

Then came the revelation of Mendel's clue, with all the manifold advances in knowledge to which it has led. The most protean assemblage of hybrid derivatives no longer menaces us as a hopeless enigma. We are sure that even the multitudinous shapes of the Cucurbits, or the polychromatic hues of Orchids—though they may range from one end of the spectrum to the other—would yield to our analysis. Methods for grappling even with these higher problems have been devised. The immediate difficulties are chiefly of extension and application. Thus the study of hybridisation and plant-breeding, from being a speculative pastime to be pursued without apparatus or technical equipment in the hope that something would turn up, has become a developed science, destined as we believe not merely to add new regions to man's knowledge and power, but also to absorb and modify profoundly large tracts of the older sciences.

Terminology.

Like other new crafts we have been compelled to adopt a terminology, which, if somewhat deterrent to the novice, is so necessary a tool to the craftsman that it must be endured. But though these attributes of scientific activity are in evidence, the science itself is still nameless, and we can only describe our pursuit by cumbrous and often misleading periphrasis. To meet this difficulty I suggest for the consideration of this Congress the term "Genetics," which sufficiently indicates that our labours are devoted to the elucidation of the phenomena of heredity and variation, in other words, to the physiology of Descent, with implied bearing on the theoretical problems of the evolutionist and the systematist, and application to the practical problems of breeders whether of animals or plants. After more or less undirected wanderings we have thus a definite aim in view.

The Uses of Conferences.

The suggestive impulse to which this great progress is due came from without, but we take pleasure in the thought that the London Conference, and no less the second gathering at New York in 1902, did much to ensure the vigorous response which that long-awaited stimulus received. Of those who have taken a chief part in the advancement of "Genetics" several were with us then, and to the interchange of ideas which ensued may be ascribed much of the keenness and solidarity of purpose with which the Mendelian clue was followed out.

Conferences, like other stimulants, are, I believe, beneficial if not indulged in to excess. There are, however, special considerations which make it desirable that people with our particular interests should occasionally confer. Genetics constitute a subject of vast range. Each worker can have experience only of some small part. Nevertheless, the various phenomena are so closely interrelated that the centre of progress may shift rapidly from one part of the field to another. No one, therefore, can safely neglect the advances made in his neighbour's territory. Sciences follow the plan of developing organisms in that they pass through stages of little differentiation, when parts are still doing the work of the whole. In these early stages inquiry must be comprehensive. The worker must be wary of narrowness. While he is engrossed, and perhaps lost, in the idiosyncrasies of Orchids a discovery may be made concerning Peas, or it may even be Mice or Lepidoptera, which is just what the orchidist requires to clear away his own obstacles. Not even the time-honoured distinction between things botanical and things zoological is valid in genetics, and I notice with satisfaction that though we meet as guests of the Royal Horticultural Society, and though by the nature of the case plants figure most in the bill, yet animals are by no means excluded.

Now Conferences, especially those informal gatherings which are to make so pleasant a feature of our present programme, offer exceptionally good opportunities for the acquisition of knowledge of this comprehensive character. In the course of these meetings we shall gain information and suggestions that would not be attainable by months of search in the best ordered library.

Practice and Science.

There is another reason why the subject of genetics is particularly appropriate to the deliberations of a Conference. I find this reason in the fact that practical and scientific workers here have equal need of each other's aid. I hesitate to add that they have equal prospects of benefiting from the partnership; for while it is clear that the mind of the practical breeder is stored with the experience that the physiologist requires, it is less certain that the practical man would recognise that the scientific experimenter had much of great value to impart to him. To this question of the practical evaluation of genetic discovery I will again refer, merely for the present noting the fact that two quite distinct classes of workers are interested in this one class of fact, and that such meetings give a capital opportunity for them to compare experiences and take stock of each other's progress. For the success of our meetings it is essential that neither the practical nor the more strictly scientific aspect should unduly prevail to the exclusion of the other. There is then abundant reason for our coming together, and it is not without due sense of the importance of the occasion that I have accepted the great honour of presiding over your deliberations.

Progress of Genetic Enquiry.

In the few moments which I can now claim it is impossible to enumerate, and much more so to demonstrate, the genetic discoveries made by various workers here and abroad since last we met. Much of this information will be given in the papers communicated to the meeting. We have with us to-day several distinguished pioneers of these inquiries. We are looking forward to hearing them speak for themselves.

It seems to me therefore that I shall most fitly inaugurate these proceedings by attempting with the utmost brevity to state the position which genetic enquiry has now reached. The difference between the present and the former standpoint is well illustrated by taking two of the common ideas current among breeders and considering how each has gained in precision. The ideas I shall speak of are those conveyed by the terms "pure-bred" and "reversion." We have at last a critical appreciation of the physiological meaning of the term pure-bred as applied to a plant or animal. In a general way every breeder is familiar with the notion that some animals and plants are pure while others are not. We have long been accustomed to distinguish the two conditions in various ways, estimating purity sometimes by truth to parental type, sometimes by the uniformity of the offspring.

* An Inaugural Address at the Royal Horticultural Society to the Third Conference on Hybridisation and Plant Breeding, by W. Bateson, F.R.S., V.M.H., on July 31.

Neither of these tests, as we now know, is valid. An individual may be impure though not sensibly different from the accepted type of its breed, and though continued breeding from an impure individual will probably in the end reveal impurity, yet several generations may be produced in succession without any such indication appearing. For example, if, in a rose-combed breed of fowls that had bred true for generations, a single-combed bird were to appear, we might formerly have supposed either that one of the parents was impure, or that a new variation had occurred. We now realise that the introduction of the single comb may have taken place in some generation indefinitely remote, and that the appearance of that feature in a perceptible form is due simply to the fortuitous meeting of two germ-cells bearing the recessive character.

The Meaning of Pure-bred.

An individual is *pure-bred* when the two cells, male and female, from which it develops are *alike in composition*, containing identical elements or characters. No long line of like progenitors is needed to produce a pure-bred plant. A purple Sweet Pea may, as we now know, have been bred from white grand-parents exclusively and yet be pure to the purple character. Conversely, a white Sweet Pea may be a seedling produced by the self-fertilisation of a purple-flowered plant, and yet be pure-bred in respect of whiteness. It matters not how the parents are bred. They may be mongrels, as heterogeneous in composition as packs of cards; but if from the two packs *similar* cards happen to be dealt, the product of these two cards is pure. And as in the cards we may consider their attributes of colour, suit and number as distinct, so in the living thing we know that the several features or physiological characteristics may be treated as distinct in the cell-divisions by which the germ-cells are formed.

From this separability or distinctness of the characters it follows that an organism may be pure-bred in one respect and cross-bred in another. I need not remind my present audience that this conception of the unity and distinctness of characters provides the solid foundation which makes the science of genetics possible. Instead of regarding genetic purity as a vague and problematical state which might or might not be attainable by a long course of selection or fixation, we now know exactly what it is and how it is produced.

It is evident that this is a piece of knowledge which the practical breeder can turn to account. In future he will work with individuals of tested composition and avoid masses, thereby greatly simplifying the work of selection and fixation. It is no exaggeration to say that in this branch of industry the breeder can now perform in four years what formerly he could scarcely have effected in twelve.

Reversion.

Take similarly the idea of Reversion, which was formerly invoked to account for the unexpected or the unwelcome, much as our ancestors appealed to the powers of evil. Reversion, as usually met with, is one of two very definite but quite distinct things. Commonly these recurrences of features the breeder supposed he had bred out are merely due to the reappearance of a recessive character. Like the single comb spoken of above, these recessives never get the chance of appearing until they are introduced into the organism simultaneously from both sides of its parentage. A proof that any given reversionary character is merely a recessive, can be got at once by observing that the reverting individuals, on being fertilised with themselves or with their like, will breed true, and at least will not reproduce the types from which they were extracted.

But in addition to this very simple sort of reversion there is another of a more complex and much more instructive kind—that which is generally known as *reversion on crossing*. The most familiar illustrations have been seen in pigeons, fowls, Sweet Peas and Stocks. This reversion to an ancestral form, which may be indefinitely distant, can occur even when types of absolute purity are crossed together. Such reversionary forms, unlike those first considered, *never* breed true in the first generation—the F_1 generation, as we call it—but in F_2 generation there must in all ordinary cases be a small but definite percentage of reversionary individuals which are then pure-bred, and thenceforth able to breed true. As we now can prove, the reappearance of the ancient characteristic is caused by the meeting together of distinct elements long parted. In some unknown way these two factors "let each other off." Both factors must be present together in order that the feature in question may be developed.

The most complex illustration yet known of the effects of interaction between factors is provided by the Ten-week Stocks investigated by Miss Saunders; where, as we now know, two independent factors must co-exist in one plant to produce hoariness in the leaves; but even if these two are together present the leaves are still glabrous unless they are also associated with two other factors which are concerned with the production of flower-colour. How much further such analysis can be carried, it is impossible to surmise. We see, as yet, no reason for supposing that the rules of inheritance now perceived in the case of the simpler properties or structures of animals and plants are not applicable also to the features we regard as higher.

There is also a special kind of reversion on crossing made famous by Darwin's experiments on pigeons. Here the reversionary type is often not perceptible in F_1—the first cross-bred generation—but appears first in F_2 when the F_1 birds have been bred together. Such a phenomenon has been made the subject of experiment by Mr. Staples-Browne, and as his results clearly indicate, the reason why the reversionary character, viz., the black barring on a blue ground, does not appear in F_1 is that this feature is obscured by the dominant blackness introduced by one of the parents. When the factors which produced the blue meet in F_2 birds, which do *not* also contain black, the Blue Rock colouring is then evident.

Such a case as this last is only an apparent difficulty. Nevertheless, I should warn you that there is a large class of alleged reversions, of a kind more economically important than these, arising in ways not yet properly understood. I allude to the appearance of reversionary "rogues" among seed-crops, where circumstances preclude the idea that we have to deal with mere recessives, and make it *prima facie* unlikely that crossing is the provocative cause. For example, in the case of Peas, such reversionary and wild-looking "rogues" with *round* seeds have been shown me by my friend, Mr. Arthur Sutton, amongst crops of highly-bred wrinkled Peas. They are regarded as indications of that general degradation or degeneration which it is supposed would permeate all highly-bred stock if selection were suspended. Now, though it is certain that in practice if the crops were neglected these hardy and productive "rogues" would soon prevail and overwhelm the pure and more delicate strain, we are no longer content to regard their presence as inevitable. In order to cope with them we must find out exactly what they are. By the strict method of breeding from individuals under proper precautions we have now the means of doing this, and not till such investigations have been made need it be regarded as the inevitable property of any high-class variety to produce rogues. Though as to this special case I make no prophecy, modern observations strongly suggest the paradoxical conclusion that there is no such thing as general degradation or degeneration. These phenomena are due to specific causes, most commonly to nothing more obscure than insect-crossing, or to unsuspected mixture with an unrecognised variety. I mention these things simply to illustrate the fact that though the precise physiological nature of reversion may seem a matter remote from practical life, it is not remote at all, but closely bound up with very important industrial considerations.

I have said that reversion on crossing is due to the meeting of long-parted factors. Conversely variation is often due to the separation or elimination of factors. In other cases it is almost certainly, though perhaps not quite certainly, due to the addition of *new* factors. Genetic research has thus provided the first indication of the physiological process which results in the birth of a variation. The consequences of this knowledge to the systematist and to the science of evolution I will not now pursue. By following the clue which the discovery of "unit characters" has provided the long range of phenomena first grouped in an orderly fashion by Darwin in *Animals and Plants under Domestication* can at last be subjected to precise enquiry. The proximate significance of many of these mysteries is indeed already made out. Only those to whom that treatise has long been a kind of *De Occultis Naturæ Miraculis* are able to appreciate what the new knowledge means to biological science.

Practical Importance.

Now once more as to the practical importance of all this. The breeder has two main objects in view, he wants to *create* novelties and to *fix* them. In the second of these objects he can, as we have already seen, expect help from genetics. As regards the creation of new forms I must not speak so confidently. Nevertheless, there is a valuable class of novelties which are really novel only in so far as they recombine pre-existing characters of known types. Such re-combinations, say of hardiness with desirable qualities of colour or shape, or of size or free-flowering habit with brilliancy, or of colours such as red and cream-yellow, belonging to distinct physiological systems, may be of great value to the breeder. If in the majority of such cases no infallible prescription can yet be given to produce the desired result, Mendelian knowledge often indicates the course which is most likely to succeed. I am not straining the truth when I say that the right course in numbers of instances is one which an operator guided by common sense alone would have studiously avoided.

But apart from any specific claim as to the immediate economic value of genetic research, let me once more take more general ground, and without fear of contradiction I will insist on the truth that with a critical knowledge of the meaning of "pure-bred" and "reversion" a new era begins. To confusion and guess-

work, knowledge and orderly experiment succeed.

The conclusions I have named and others like them have been arrived at by statistical observations of a somewhat arduous kind. An account of these technical proceedings scarcely falls within the scope of this address. I must, however, dwell for a moment on the fact that the processes of "segregation" which bring about the outward and visible facts of heredity are in essence *symmetrical* processes. It has long been known, ever since the beginning of microscopical research, that cell-division often appears to be a symmetrical process. We have now learnt that this visible symmetry is in the main a true representation of the qualitative symmetry by which the qualities or characters are distributed among the developing germ-cells. No one can yet declare that plans of distribution following some higher order of complexity do not exist; but analysis of the simple cases will keep us employed for many a year, and not till the symmetrical phenomena of heredity have been exhaustively explored can we contemplate a further expedition into the unknown. Of one thing at least we may be sure: that heredity is a regular phenomenon, in many of its manifestations simple, and amenable to experimental methods of research. To have said as much in 1898 would have been only to make a pious ejaculation of personal faith. Before our meeting in 1902 the change had begun. We could deal with simple cases involving only two types of individuals. When a family contained on an average three of one type to one of another, or equal numbers of both, we knew what the fact meant. Now we can deal with much more difficult cases. The number of types does not trouble us. We understand the ratios 9 : 7, and 9 : 3 : 4, 27 : 9 : 28, and many variations on these simpler themes. All these can be shown to be produced by the chance combinations of germ-cells, or "gametes," produced by symmetrical divisions.

The Units—their nature.

But ever in our thoughts the question rings, what *are* these units that bring all this to pass, which in their orderly distributions decide so many and perhaps all of the attributes or faculties of each creature before it is launched into separate existence? Colour, shape, habit, power of resistance to disease, and many another property that might be named, have one by one been analysed and shown to be alike in the laws of their transmission, owing their excitation or extinction to the presence or absence of such units or factors. Upon them the success or failure of every living thing depends. How the pack is shuffled and dealt we begin to perceive: but what are they—the cards? Wild and inscrutable the question sounds, but genetic research may answer it yet. Substances which excite disease or confer resistance, which preserve health or produce deformity have been extracted, and it may not be more impossible to determine the nature of the two critical factors which excite hoariness or colour in a plant.

It is not only the breeder of animals or plants who is concerned to know the truth about heredity. The results of genetic research affect every branch of physiological or sociological inquiry. Too long has science been content to explore the specialised and outlying functions of the body and to neglect the primary, central and all-controlling function of heredity, on which the rest depend. Such neglect manifestly arose from the curious delusion that the laws of breeding were untraceable. With the Mendelian renascence that dark age has ended.

As a hopeful sign it may be noticed that in the United States the Carnegie Institution has lately equipped a station for the experimental study of Evolution. In England, where through Darwin's genius the study of evolution first became a reality, the country in which the art of breeding has for ages occupied a place unequalled in other lands, no such opportunities exist. The pursuit of these objects demands facilities of a special kind such as neither technical colleges nor the laboratories of the Universities are able to supply. Sooner or later perhaps an effort will be made to provide equipment of this kind in England. Whenever such an institution as that I contemplate comes to be designed, let it not be tied down to the pursuit of directly economical results. When someone says to me—"But can't you breed a Derby winner, or do something useful?" the reproach does not disturb my equanimity. In parenthesis let me remark that though in the attempt to discriminate among animals all good enough to win, science may be as much at fault as common sense, yet it would not surprise me if science were to devise a way of breeding even race-horses which would not produce about a hundred wasters for one fit to win—and yet I understand that common sense remains content with that rather modest attainment after two centuries and a half of steady trying.

The great advances in the application of science have generally become possible through discoveries made in the search for pure knowledge. Mendel's incomparable achievement, with all that it imports both to science and to practice, was brought about by the resolute determination to get to the bottom of one particular problem in hybridisation, a problem too without any very obvious practical application, and we may rest assured that in no other spirit can natural knowledge be more profitably pursued.

NEW OR NOTEWORTHY PLANTS.

EREMURUS × MICHELIANUS.

M. Correvon sends us a specimen of a hybrid Eremurus, which originated spontaneously in the garden of the late M. Marc Micheli, near Geneva. Its parents are assumed to have been E. Warei and E. Bungei. The leaves are linear, very acute, about 68 cent. long (say 27 inches), 12 mill. (½-inch) broad, three sided, deeply channelled on the upper surface, acutely prominent beneath glaucous green, minutely denticulate at the edges. The flower scape is described by M. Correvon as flexuose. It measures about 2 metres (6 to 7 feet), and is surmounted by a many-flowered raceme, which attains an additional height of a yard and upwards. The bracts are membranous, with a broad base tapering upwards into a very long acumen. Pedicels spreading on all sides, thinly disposed, about 1 inch long, slender, brownish. Flowers about 2 cent. (¾-inch) across; perianth segments oblong obovate, primrose-yellow, channelled in the centre on the upper surface, with a prominent reddish-brown stripe on the outer surface, stamens 6, filaments slender, yellow, glabrous, equalling the perianth segments; anthers orange-coloured; ovary globose, obscurely lobed, three-celled, with numerous large wedge-shaped seeds attached to the axile placenta. Style simple, rather longer than the stamens, stigma minute.

The flowers began to open on June 20, and lasted about a month.

M. Correvon suggests that the name of M. Micheli should be attached to this plant, and that it should be named E. × Michelianus.

REMARKS ON THE CONDITION OF THE FRUIT CROPS.

(*See Tables and Summaries, ante, pp.* 64-70.)

0, SCOTLAND, N.

Orkneys.—A fortnight of very severe weather, beginning on May 20, spoiled all the fruit crops. *Thos. MacDonald, Balfour Castle Gardens.*

Sutherlandshire.—The cold, wet month of May, and the frosts which were intermittent even until the end of June, were extremely injurious. The weather in July was exceedingly dry. Our soil is of heavy loam, overlying clay. *John McIver, Skibo Castle Gardens, Dornoch.*

1, SCOTLAND, E.

Aberdeenshire.—Black Currants and Raspberries are very fine crops. Strawberries were only average. Gooseberries were almost a failure. The weather in May was disastrous, yet I never saw the trees look better than they did when in flower. *James Grant, Kildrummon Gardens, Kildrummon.*

—— The fruit crops in this district are almost a failure, owing to the continuation of frost all through April, followed by an exceedingly cold and wet May. The soil is of a heavy nature, and the subsoil is clay. Crops of all sorts are about ten days later than in an average season. *John Brown, Delgaty Castle Gardens, Turriff.*

Banffshire.—The cold winds and frosts of May 16 and 17 caused much damage to fruit crops in this district. *A. Morton, Cullen Gardens, Cullen.*

Clackmannanshire.—Rain and cold winds are worse for fruit blossom than is frost. Last year I had an Apple tree that was covered with blossom, but it rained continually when the flowers were open, and the petals became stuck to each other, no pollen was shed, and hence there was no fruit. In cold, wet weather the stigma seems dull and lifeless. *A. Bruce, Alloa Gardens, Alloa.*

East Lothian.—An abnormal amount of rain—7 inches—fell from May 1 to June 1 inclusive. Apple blossom produced no pollen. Strawberries failed through want of rain early in July. It is the worst fruit season since 1880. The soil is light, contains much gravel, and is deficient in loam. *R. P. Brotherston, Tynninghame, Prestonkirk.*

Fifeshire.—I attribute the cause of the failure of fruit here to the very cold and inclement weather we had when the trees were in bloom, and to the late frosts which stripped some of the trees after the fruits had set, especially Black Currants and Morello Cherries. *Chas. Simpson, Wemyss Castle Gardens, East Wemyss.*

Forfarshire.—There was a good show of fruit blossom of all kinds in spring, but the weather conditions were not favourable for a good set. Pears are almost a failure, while Apples are a light crop. Strawberries have been much affected by the drought, and the crop here is a small one. Small fruits are also scarcer than usual, with the exception of Raspberries. *W. McDonall, Brechin Castle Gardens.*

—— The almost entire failure of most of our fruit crops this season we attribute to cold winds when the trees were in blossom. The soil is a light loam, over a subsoil of sand. *F. Wilson, Glamis Castle Gardens, Glamis.*

—— In this district summer pruning is generally done about the middle of July, commencing with Cherries and Plums, following up with Pears and Apples. Results are good. The cold, wet, and sunless weather, with prevailing frosts during the night, throughout the month of May, had much to do with the failure of the fruit crops in this district. Along the coast the soil is of a light, sandy loam, with subsoil of gravel and sand; inland, the soil is of a heavy loam with clay subsoil. *William Allison, The Gardens, Seaview, Monifieth.*

KINCARDINESHIRE.—There is no doubt in this district what has adversely affected this season's fruit crop; it was severe frosts and cold winds, accompanied by snow and sleet, when the trees were in blossom. We had 10° of frost twice in May. The soils on Deeside are mostly light on a gravel bottom. *John M. Brown, The Gardens, Blackhall Castle, Banchory.*

MIDLOTHIAN.—Fruit trees here of all kinds had an extra quantity of blossom. Severe frosts about the middle of March, and later, completely destroyed the Plum and Gooseberry crop. Much wet weather and very low night temperatures during April and May have caused the worst crop of Apples and Pears there has been for many years past. Strawberries, Raspberries, and Currants are average crops. The soil is light and sandy, the subsoil being of gravel. *James Whytock, Dalkeith Gardens, Dalkeith.*

6, SCOTLAND, W.

DUMFRIESSHIRE.—The blossom was abundant, but late. The actual frost was not severe, and no damage could be traced to its direct agency, but the low temperature, the absence of sunshine, and the almost standstill of vegetation during the flowering period accounts for the big gap in the Plum crop. The Apple crop is much better, the weather having been bright and cheerful during the flowering period. The following varieties have a full crop, and generally give us the best results: Peasgood's Nonsuch, Ecklinville Seedling, New Hawthornden, Lord Suffield, Stirling Castle, Lane's Prince Albert, Lord Grosvenor, Tower of Glamis, and Duchess of Oldenburgh. No amount of pruning has rendered Gascoyne's Seedling or Prince Bismarck suitable for this district. Newton Wonder, Schoolmaster, Christie Manson, Byford Wonder, and Alfreston are still in the experimental stage with us. The soil is clay-loam, with a heavy clay subsoil. *John Urquhart, Hoddom Castle Gardens, Lockerbie.*

STIRLINGSHIRE.—Late frost and cold east winds in May account for the failure of the hardy fruit crops. We had 15 degrees of frost in the last week in May. The soil is a light, sandy loam; subsoil clay. *Alex. Marshall, Ballikinrain Gardens.*

WIGTOWNSHIRE.—The dry, harsh winds and frequent frosts in April destroyed the prospect of crops from Plums, Peaches, and Apricots. Late Apples are still more disappointing, for there having been no frost during the flowering period good crops were expected. Wet, dull weather for days together probably had an adverse effect upon the blossom, and prevented it setting. The soil is a good working loam, and the subsoil gravel or sand. *James Pay, Galloway House, Garlieston.*

2, ENGLAND, N.E.

DURHAM.—The late spring frosts and cold east winds when the trees were in blossom told seriously against the fruit crops. We had a splendid promise, the blossoms big abundant, but on May 23 we had from 6 to 8 degrees of frost. *James Noble, Woodburn Gardens, Darlington.*

—— The fruit crop generally was seriously affected by sharp frosts almost nightly up to May 20, also by heavy showers of hail and snow up to a very late date. *James MacIlar, Smeaton House Gardens, Howden-le-Wear, R.S.O.*

YORKSHIRE.—Bloom was abundant and promising, but except that of Apples, Strawberries, and Raspberries, all was destroyed by the general low temperatures throughout May. The soil here is moderately good loam above Yorkshire grit. *J. Simpson, Studfield, near Sheffield.*

—— In the latter part of April and early part of May, we had a long spell of frost and hail, with cold winds, which ruined a large quantity of the blossom, which before was very promising. Gooseberries are the worst crop I have had for some years. Apples are good, also Black and Red Currants. Strawberries have suffered from drought. *A. E. Sutton, Castle Howard Gardens, Welburn.*

3, ENGLAND, E.

CAMBRIDGESHIRE.—The severe frosts in April and May and the cold, north-east winds practically ruined the fruit crops here this season. *R. Alderman, Fabraham Gardens, Cambridge.*

ESSEX.—Undoubtedly the cold east and north-east winds in late spring were responsible for the almost complete failure of Plums. These, at the time of the cold winds, were in full bloom, and presented the appearance of having been scorched. Fortunately the dryness of the atmosphere and protection of walls saved Apricots, Peaches, and Nectarines. The early blooms of Strawberry, although not open, were destroyed here. *Arthur Bullock, Copped Hall Gardens, Epping.*

—— The frosts in April and in the early part of May were the cause of the almost total failure of the Pear and Plum crops in this district. The soil here is generally a sound loam, resting on a clayey subsoil. *H. W. Ward, Lime House, Rayleigh.*

LINCOLNSHIRE.—Sharp frosts and cold N. and N.E. winds killed many of the blossoms before they had set, and those that had set being weak, owing to such a wealth of blossom, could not withstand the unfavourable weather, and fell off.

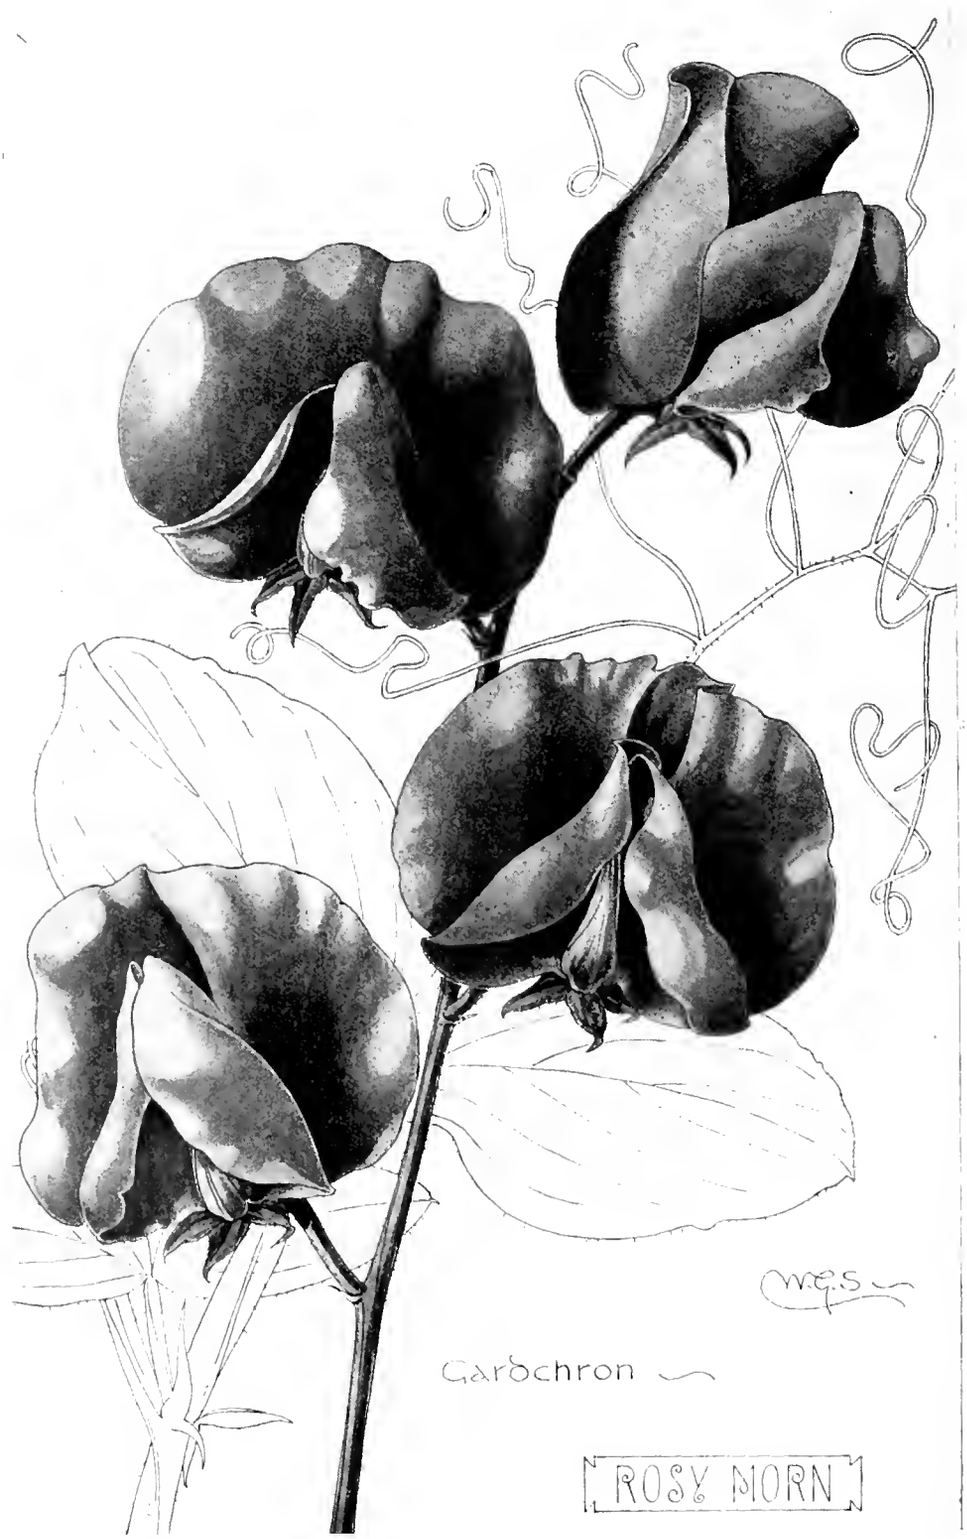

FIG. 34.—SWEET PEA "ROSY MORN," WHICH OBTAINED AN AWARD OF MERIT AT THE R.H.S. MEETING ON JULY 17 WHEN SHOWN BY MESSRS. H. CANNELL AND SONS; COLOUR REDDISH-ROSE. (See page 54.)

The soil is a brown loam on blue clay or ironstone. *H. Virden, Harlaxton Manor, Grantham.*

NORFOLK.—The partial failure of the fruit crops this year is due to the exceptionally severe spring frosts. In many places Strawberries and Apples were partly ruined before the flowers even opened. Large quantities of the latter dropped on account of drought, which, coupled with cold winds and frost, has caused most vegetation to be unsatisfactory. Pears, Plums and Black Currants, except in one or two favoured positions, are almost a complete failure. Rarely was there such a wealth of blossom as prevailed this season, but some growers complain of the ravages of sparrows and bullfinches among the Apple-buds and those of small fruits The soil and subsoil vary greatly, but for the greater part the soil is sandy, overlying chalk or gravel. *E. C. Parslow, Shadwell Court Gardens, Thetford.*

—— The fruit crops have suffered greatly from east winds, late frosts, and mildew Apples are a partial crop, and the fruits are still dropping, being badly affected with moth and mildew. Strawberries were a very good crop, but badly mildewed, the Laxton and Royal Sovereign faring worst. Raspberries are a grand crop, especially the variety Superlative. Gooseberries suffered in the young state when exposed to the east winds and frosts. Pears are badly mildewed. Early Potatos are turning out grand, and late varieties are looking well. In some places the second earlies are infested with a new disease, to be seen in the curling of the leaves, and turning rusty, with only very small Potatos at the roots. We have a mixed soil, with gravel subsoil. *J. W. Braithrook, The Gardens, Ketteringham Park, Wymondham.*

SUFFOLK.—Dry weather has most affected our fruit crops this season, as we had practically no rain in April or May. Pears and Apples set well, but dropped later in large quantities, owing to the drought. The soil is mixed, some being very heavy, and others the reverse; the subsoil is of gravel and sand. *Thos. Simpson, The Gardens, Henham Hall, Wangford.*

(To be continued.)

OUR PORTRAIT SUPPLEMENT.

THE portraits which we are privileged to lay before our readers in this issue are those of several who are participators in the Hybridisation Conference as active members, as guests or as hosts.

The President is Mr. WILLIAM BATESON, of Cambridge, a thinker and investigator who has been foremost in reducing to law and order the chaotic mass of detail relating to variation and heredity. A keen observer in well-trodden fields of activity, he has also broken new ground by his patient investigations. He has dealt with the question of "Sports" or discontinuous variations, he has not only rescued from oblivion the remarkable experiments and inferences of Mendel, but has greatly extended them by applying them to poultry as well as to Chinese Primroses, Sweet Peas, Stocks and other plants. Whereas before his time we had to rely on casual observation and haphazard experiment, we have now learnt that these matters may be co-ordinated, and reduced to system and numerical proportion. The vague and indefinite has, through his experiments, become to a large extent and in an ever-increasing degree replaced by what is fixed and capable of demonstration. If we have had to unlearn some of our cherished convictions and abandon some of our shibboleths, what is that in comparison with the establishment of the truth and the influx of light in previously dark places?

M. MAURICE DE VILMORIN, the brother of the ever-lamented Henry, is one of a family that has accomplished so much for the benefit of humanity in experimental horticulture that he needs no introduction to our readers. The arboretum at Les Barres formed by M. MAURICE DE VILMORIN is one of the richest and most remarkable of its kind. His relations with Chinese explorers and missionaries has enabled him to get together a most interesting selection of plants. To him has fallen the honour of being the first in Europe to flower the Davidia, of which an illustration was given in our columns in June 2 last, p. 346, M. DE VILMORIN has raised some hybrid Roses, crosses between R. rugosa and R. foliolosa.

LEOPOLD DE ROTHSCHILD, Esq., C.V.O., comes of a family renowned, amongst other things, for their patronage of science and art, including horticulture. Both at Ascott and at Gunnersbury, Mr. DE ROTHSCHILD exercises his tastes for gardening, and the members of the Conference who availed themselves of his hospitality at Gunnersbury on Friday had the opportunity of seeing one of the most interesting and remarkable gardens in England, the more remarkable as it is in immediate proximity to London and Brentford, not the most favourable localities for the pursuit of gardening.

Prof. JOHANNSEN, of Copenhagen, demands cordial recognition at our hands, not only for his researches on heredity, but also for his fruitful experiments on the action of ether in first retarding growth and then in promoting the flowering of plants. What the refrigerating chamber does with some plants, the ether treatment does for others. M. JOHANNSEN occupies a very high position among those who, by their scientific experiments, have promoted the progress of modern horticulture. M. JOHANNSEN, in a recent work, shows a weak place in most experiments quoted in favour of "selection." He proves that to obtain really new and stable varieties plants should not be chosen which show a particular characteristic most clearly, but the descendants of one or more races that have possessed from the beginning the qualities which it is sought to intensify by selection should be isolated for observation. Selection, properly so called, consists of the wholesale selection of a number of plants belonging to different generations. Cultivation by pedigree, by isolating each year the descendants of a plant of pure origin, accompanied with the exact determination of the variation of characters, is the only rapid and sure way of discovering aberrant and new, sometimes better, forms which occasionally occur in cultivation.

M. A. PEETERS, of Brussels, one of our guests, finds an appropriate place in our columns as the raiser of various hybrid Orchids. Among the better known crosses raised by M. PEETERS are:—Cattleya Mrs. Myra Peeters, one of the finest, pure white Cattleyas obtained between two albinos—C. Gaskelliana alba and C. Warneri alba, and therefore interesting as it proves that abnormal characters such as albinism may be perpetuated by seeds, Odontoglossum × Lambeauianum vars., illustrated in the *Gardeners' Chronicle* November 4 and December 23, 1905; Cattleya × Fabia Marie de Wavrin, Lælio-Cattleya × Herode (L.-C. elegans × C. O'Brieniana); Lælio-Cattleya × Stepmanni, Lælio-Cattleya × Wrigleyi (L. anceps × C. Bowringiana). This is also raised by Messrs. VEITCH.

M. NÖEL BERNARD, of the University of Caen, is an investigator whom we rejoice to welcome among us. His researches into the "symbiosis" or co-operative action observable between certain fungous moulds and various Orchids, opens up a new and most interesting branch of study, the practical importance of which needs no pointing out. If we know now why the culture of some Orchids is relatively easy, whilst others have so far taxed the resources of our cultivators, it is M. BERNARD'S researches that have furnished a clue to what was previously mysterious.

Prof. PFITZER, of Heidelberg, is well known among botanists and Orchid-lovers for his valuable work in the classification of Orchids. Former students have been content to base their researches mainly on the differences in floral structure, but Prof. PFITZER has shown that very valuable points of distinction are to be found in the mode of growth of the living plant. In this manner he commands the sympathies of the Orchid-grower as well as of the botanist.

PHILIPPE DE VILMORIN. What shall we say of him, but that he is the son of his father, the late HENRY DE VILMORIN, who was so well known and so much beloved among us? In taking part in this Conference he only does what his father did before him, and indeed in experimental horticultural generally, PHILIPPE DE VILMORIN worthily carries on the traditions of his house.

Prof. WITTMACK, till lately the secretary of the Prussian Horticultural Society at Berlin, has had a long and honourable career as a botanist He has devoted his talents to the elucidation of many problems in horticultural and agricultural science. He has visited the United States with the same objects in view, and is deservedly held in the highest esteem among his colleagues

There are many who took part in the former Conference whose portraits are not repeated on this occasion, though we are happy in the knowledge that we have them still working among us, nor have we thought it necessary to repeat the portrait of the president of the Royal Horticultural Society, who has done so much to promote the success of this gathering.

ROTHAMSTED INVESTIGATIONS.*

The memoranda of the Rothamsted agricultural experiments issued yearly by the Lawes Agricultural Trust, mainly for the use of visitors, has this year been entirely altered in character and usefulness; it now assumes a valuable brochure, not only as a "guide to the experiments," but a handy manual for those who undertake the teaching of agriculture.

The work includes many illustrative diagrams and much important matter taken from Mr. A. D. Hall's (the director) exhaustive book of the Rothamsted experiments.

The story of the invaluable work done at Rothamsted has been so frequently told that we need give but a brief resume of the new brochure before us.

The experiments were commenced by the late Sir John B. Lawes, Bart., in 1843, on a soil which is described as a rather heavy loam resting upon chalk, capable of producing good Wheat when well manured; not sufficiently heavy for Beans, but too heavy for good Turnips or Barley.

The average produce of Wheat in the neighbourhood is about 22 bushels per acre, Wheat being grown once in five years. The rent varies from 20s. to 26s. per acre, tithe free. The soil is fairly uniform in the different fields, and consists essentially of a heavy loam containing little coarse sand or grit, but a considerable amount of fine sand and silt and a large body of clay. In consequence, the soil has to be worked with care, becoming very sticky and drying to impracticable clods if moved when wet. It "runs together" if heavy rain falls after a tilth has been established, and then dries with a hard, unkindly surface, these difficulties being much exaggerated on the plots which have been farmed for a long time without any supply of organic matter in the manures.

AGDELL FIELD. CROPS GROWN IN ROTATION.

This field was put under experiment in the year 1848, and is farmed on a four-course rota-

* Rothamsted Experimental Station. Guide to the Experimental Plots. 1906. John Murray, Albemarle Street, W.

tion of Swedes, Barley, Clover (or fallow), and Wheat. It is divided into three main portions, one of which has received no manure; the second, phosphates and potash; and the third, phosphate, potash, and nitrogen. The manures are applied for the Swedes only, the other three crops of the course being grown without manure.

In this field the long-continued cropping on the portion without manure affects the successive crops in rotation very differently. The Swede crop is least capable of growing in the impoverished soil, and is reduced to less than a ton per acre; the Clover and Barley crops are also small, but the deep-rooted Wheat crop is comparatively little affected, and yielded as much as 19·6 bushels per acre in 1903, the 56th year without any manure. With phosphate and potash, but without nitrogen, the Swedes continue to give a fair crop; the Barley and Wheat are but little better than on the unmanured plot, while the Clover grows almost as freely as on the completely manured plot. When the portion allotted to Clover grows a good crop, the residues of the Clover have a very beneficial effect upon the succeeding crops of the rotation; the Wheat is increased by something like 15 per cent.; the roots (although manured) are slightly better, and the Barley following the roots still shows the value of the preceding Clover. No such residue seems to be left behind by the Bean crop whenever that is taken in the rotation instead of Clover.

On the unmanured portion the Clover shows no effect on succeeding crops, because there its growth is too small to leave behind any residue of nitrogen.

BARNFIELD. MANGEL WURZEL.

The experiments upon Mangels began in 1876, but the land had been receiving similar manures for other root crops since 1856.

The value of farmyard manure in growing Mangels is strikingly evident, especially when they are grown continuously on the same land.

In favourable seasons it is possible to obtain good crops by the aid of artificial manures alone, as seen in 1905, when 31½ tons per acre were obtained, but in ordinary years the bad texture of the soil which results, and its tendency to lose water on account of the lack of humus, affect both the germination of the seed and the growth of the plant in its early stages.

THE PARK. GRASS-LAND GROWN FOR HAY EVERY YEAR.

The experiments upon the mixed herbage of grass-land began in 1856. The land has been in grass as long as any recorded history of it exists, for some centuries at least. The plots, of which there are 20 in all, are variously manured, two of them remaining without manure during the whole of the 50 years. Taking the average of this long period, the unmanured plots have produced rather more than a ton of hay per acre per annum, and there is no sign of approaching exhaustion or great falling off in crop from year to year. The impoverishment of these unmanured plots is more to be seen in the character of the herbage than in the gross weight of produce. Weeds of all descriptions occupy the land, and the relative proportion they bear to the grasses and Clovers has increased from year to year, until they now constitute nearly one-half of the herbage.

BROADBALK FIELD. WHEAT.

The experiments on the continuous growth of Wheat were begun in 1843, but for the first eight years the manuring was of a varied description, so that only three of the plots have received the same treatment during the whole of the sixty years. The plots as seen to-day began in 1852. On plot 3 Wheat has been grown without manure every year since 1843; for four years previously no manure had been applied, so that the present crop (1906) is the

FIG. 35.—GRAMMATOPHYLLUM SPECIOSUM AS IT FLOWERED IN SIR TREVOR LAWRENCE'S COLLECTION. (From a photograph obligingly supplied by Sir Trevor.)

sixty-seventh without manure. After a drop in production during the first few years the yield has been practically constant for the last forty years, fluctuating only with the seasons, and showing no immediate prospect of declining. The average crop has amounted to about 12½ bushels per acre, approximately equal to the average Wheat yield, taking the whole world over. With potash and phosphates alone, very little more Wheat is produced than without manure, but the crop is found to increase with each addition of nitrogen, rising from 24 bushels to 37 bushels of grain; but the straw is even more affected by the free supply of nitrogen, increasing from 21½ cwts. to 41 cwts. per acre as the nitrogen is doubled or trebled.

HOOSFIELD. BARLEY.

Experiments on the continuous growth of Barley were begun in 1852. The manures applied to each plot have practically been unchanged since, so that the plots to-day show the effect of more than fifty years' continuous cropping of Barley under the same treatment. The great importance of phospheric acid to the Barley crop is most strikingly manifest both in the general appearance of the plant and in the total produce. Where nitrate of soda is used as the source of nitrogen, the soda liberates sufficient potash from the soil to supply the needs of the Barley, but with ammonium salts the omission of potash tells upon the yield.

Particulars of experiments with Wheat alternated with bare fallow are also given, and in another field investigations on the residual value of manures is being carried out. Experiments on Potatos and various leguminous crops are conducted, and meteorological observations, including the measuring of the rainfall in a gauge which is one-thousandth of an acre in area, have been taken since February, 1853. *J. J. Willis, Harpenden.*

BURFORD, DORKING.

(See Supplementary Illustration and fig. 35.)

THE cool, shady entrance to the charming estate of Sir Trevor Lawrence, Bart., between tall trees, with their trunks clad with Ivy and the ground beneath carpeted with Ivy and Ferns, the carriage drive between rows of pyramidal Cypres, across the smooth lawn, bordered by shrubberies and bounded by the steep, crescent-shaped slope of Box Hill, the chalky soil of which shows white between the thick growth of Yew, Box, Viburnum, and other bushes which clothe its surface are well adapted to the pleasant homestead and pretty gardens surrounding it.

Sir Trevor and Lady Lawrence, who are among the most liberal supporters of horticulture, have always taken the greatest interest in gardening matters, and the Burford Gardens have world-wide fame, especially for their magnificent collection of Orchids.

But to many visitors the out-door gardens are the most interesting, as in them are always found a number of new or rare novelties, flowering for the first time, and an equally interesting lot of fine old plants displaying themselves in great beauty.

In the enclosure between the plant houses delicate plants are tried, and many are rendered quite hardy. Here the scores of fine white and rose coloured heads of bloom on the many specimens of Crinum Moorei, C. Powelli, and its pure white variety, all of which have been grown without protection for many years, are in great beauty. Other species are being tried in the same way. Near by Gerbera Jamesoni is also acclimatised, and freely sending up its vermilion-coloured flowers. Eucomis punctata and some other Cape bulbs are also now in flower; a pyramidal bush of Asparagus acutifolius is a large specimen, and other species are being tried out-doors. In the centre the Burford plan of growing the showy rose and yellow-coloured Water Lilies in compartively small tubs sunk in the ground is well exemplified, the plants being now in bloom, and arranged beside the tubs are many-flowered specimens of the white Lilium longiflorum and the yellow Cassia corymbosa, which, like the tall blue Solanum Wendlandi and a few other plants, proved to be not quite hardy in this locality, are sheltered in the winter. Lathyrus pubescens, a pretty, light blue

MR. W. BAIN, HEAD GARDENER AT BURFORD.

variety, is in bloom, and in the beds beyond, bounded by Sweet Peas, Sweet Briar, and Penzance Briars, and set out with pillars and arches of Roses, are many beds of uncommon plants in flower. Of the Roses an arch and pillars of Dorothy Perkins display it excellently, and Lady Gay and others are very effective.

Members of the Poppy family and of the Campanulas thrive well at Burford, and the handsome white Romneya Coulteri has many of its satin-like blooms. A bed of the double Welsh

MR. W. H. WHITE, ORCHID GROWER AT BURFORD.

Poppy Meconopsis cambrica flore pleno is a mass of flower; so also is the bright yellow Hunnemannia fumariæfolia and the copper-orange coloured Eschscholtzia crocea Mandarin. Shirley Poppies are always beautiful, and the beds at Burford show them at their best. Among the Campanulas a bed of C. macrostyla is a mass of lilac and purple flowers; a Burford novelty, for which a First-Class Certificate was obtained, Platycodon grandiflorum flore pleno, is of a fine purplish blue. To find the best varieties and to plant them in sufficient quantities to show them at their best is one of the methods tending to the success obtained at Burford, and hence the beds of Pentstemons, Phloxes, Violas, Delphiniums, and other hardy perennials are very effective.

Nor are the lesser Alpines neglected. A bed of various species of Gentian contains an interesting set, including the new Gentiana Lawrencei, which, it is hoped, will flower soon.

Passing through the winding walks we note beds of Richardia hastata and another Richardia fully in bloom, and which have been acclimatised out-doors; a fine and fragrant bush of Sambucus canadensis, pretty in leaf and flower, and which ought to be more frequently planted; the Flame Nasturtium (Tropæolum speciosum) trailing over some of the shrubs; some pretty arches of Clematis, of which C. Etoile Rose is the best, both for freeness of flower and growth; a plume-bearing mass of Apera arundinacea; a patch of Calochortus clavatus, which is one of the showiest; another of the bright blue Dropmore variety of Anchusa italica, one of the best of hardy blue flowers; Verbena "King of Scarlets," large in truss and bloom, and of brilliant colour; Tamarix hispida, flowering Heath-like, in small plants; and a large number of other pretty and rare flowers.

In the deep, shady dells, with tall, slender trees, and an undergrowth of interesting plants and shrubs, are a number of very strong Eremurus, which have just passed out of flower; some good specimens of Bamboos, Ferns, Azaleas, Rhododendrons, &c.

From the house there is a fine view across the smooth lawn, with its ornamental fountain and basin of coloured Water Lilies, the lobe-shaped beds around which are planted with dwarf scarlet bedding Begonias and blue Lobelias. To the right the scene expands over the meadows, and in front rises the steep face of Box Hill. Pretty and fragrant plants are arranged in the beds, some of which are of Heliotropes, others of Cannas, Nicotiana Sanderæ, Rehmannia angulata, Bamboo-like Eulalia japonica variegata, and Zebrina (quite hardy here), and a number of the newer decorative plants. The soil and situation of Burford present peculiarities which it is requisite to understand before such success can be had; but Mr. William Bain, for so many years head gardener there, and whose photograph we present to our readers, has long ago learned how to turn even the seeming difficulties to some advantage.

THE PLANT HOUSES.

In the cool houses is a fine batch of the blue Lobelia tenuior; also one of the Burford strain of Streptocarpus, celebrated for its large flowers and for the prettily-marked rose-coloured forms. The warm houses contain a very fine lot of scarlet and white spotted, and scarlet Anthuriums; some grand red-scarlet heads of bloom on Ixora macrothyrsa; the large blue Nymphæa gigantea; a case containing the Jewel-plants (varieties of Bertolonia, Sonerila, &c.; the reddish-salmon Crossandra undulæfolia—a very pretty decorative plant; a collection of Eucharis, some in flower; Strelitzia juncifolia, sending up bloom, etc.

THE ORCHIDS

have been frequently noted in these columns. Too much cannot be said of the richness of the collection, or the vigour of the plants under the care of Mr. W. H. White, the writer of our weekly calendar on "The Orchid Houses." In the cool Masdevallia house are some brilliantly-coloured Masdevallias and some pretty small species; the Epidendrums and Sobralias now, as always, have some in bloom; Platyclinis filiformis has over 100 spikes showing; Vanda "Agnes Joaquim" and the remarkable hybrid V. "Marguerite Maron," are finely in bloom, as are also some show Cattleyas; Lælio-Cattleyas and a few of the splendid collection of Phalænopsis; an interesting lot of Bulbophyllums, including

a large mass of the fine B. longisepalum; Barkeria spectabilis, and a host of other pretty things.

But the most remarkable sight at Burford, perhaps, is the long stage of hybrid seedling Orchids, which closely cover the surface of the pots in which they are pricked off, and at a distance resemble a batch of mosses as grown by market gardeners for decorative purpose. At fig. 35 we reproduce a photograph of the giant Orchid Grammatophyllum speciosum as it flowered at Burford, the only place at which it has flowered in this country. A fine portrait of Sir Trevor Lawrence was given as a supplement to our issue for July 30, 1904.

THE ROSARY.

THREE GOOD ROSES.

Two Roses that have done exceptionally well this rather dry summer are the beautiful pink Baroness Rothschild and the bright red Cheshunt Hybrid. In a Hampshire garden they have been in full bloom since quite early in the summer, and the constant succession of blossoms, particularly in the case of the Cheshunt Hybrid, makes them very valuable varieties to any amateur. Both kinds do well even in a rather dry sandy soil of shallow depth, and in the garden referred to they thrive in the midst of a far too luxuriant growth of Evergreen shrubs, with several Lime, Beech, and Fir trees in close proximity. The only fault to be found with Baroness Rothschild is that it has no scent, but after all, even if wanted for cutting, this is not a very great drawback, and you may grow plenty of varieties which have exquisite perfume but not half the beauty of this fine sort. Madame Carrière, the free-blooming climber, has done wonderfully well also this year on a pergola in this same Hampshire garden. *East Sussex.*

CULTURAL HINTS FOR AUGUST.

The budding of the Manetti and Multiflora stocks can be proceeded with, and where there have been abundant rains the stocks will now run freely. The earliest budded plants which have "taken" should have the ties loosened at the first opportunity to prevent them cutting into the bark. If the first buds have failed on the Standard Briars, there is yet time to insert others, which should be put as near the first as possible. The shoots on the early budded Briars may be shortened back to within 8 inches of the bud towards the end of this month. All the Hybrid Perpetuals, Teas and Hybrid Teas, that have flowered during July, can be pruned back a little to induce fresh growth and a later display of bloom. With regard to the climbing varieties, when the flowering wood is cut away it is a good plan to lay in the best ripened shoots of the current year's growth for next year's flowering and then apply a good surface mulch of manure to the roots, following this with a good watering. The following varieties will respond admirably to this treatment: Année Vibert, Climbing Perle des jardins, Madame Bernard, Belle Lyonnaise, and W. A. Richardson. All the above are useful alike for growing upon pillars, arches, pergolas, &c. Bush Roses that have grown too large or have lost their shape, but are of a good variety and desirable to keep, can be layered, the wood being now sufficiently firm for the purpose. Take out a trench some distance from the stem, and according to the length of the shoots, then bend them down against the back of the trench which will support them nearly upright. After making an incision halfway through the wood about 1 inch long, and before filling in the trench, work in some leaf-mould, sandy grit, and burnt earth. Now fill in the trench and secure each shoot with a thin stick, making all firm. Short-jointed cuttings obtained from side shoots taken off with a heel of the Hybrid Tea and Tea-scented varieties will root freely if inserted at the present time. Remove the lower leaves and insert the cuttings in well-drained sandy loam in a cold frame in a shady position; afford a good watering, and provide shade as required. The earliest forced Pot Roses that have been standing out in the open air can now be repotted or top-dressed. If the plants were freshly potted last season a good top-dressing will suffice now. This can be done by taking off a few inches of the surface soil and replacing it with good turfy loam and a liberal proportion of bone-dust, soot, and burnt earth. Examine the drainage and make it perfect. For the Tea and Noisette section add a little sand and leaf-mould. In repotting, shake out most of the old soil and, according to the condition of the roots, use the same sized pot, or pots 1 inch larger in diameter, which should be quite clean. For drainage use one large crock placed hollow-side downwards, and then make up to about an inch in depth with a few knobs of charcoal and bones. The same compost used for top dressing can be employed for repotting. If the loam had been stacked with a little manure some months in advance of being used so much the better. Pot firmly with a potting-stick, and when finishing leave a clear inch below the rim of the pot for watering; thoroughly soak the soil through, but afterwards water rather sparingly during the autumn. Place the plants outside on a base of ashes in a shady position. *J. D. G.*

The Week's Work.

THE ORCHID HOUSES.

By W. H. White, Orchid Grower to Sir Trevor Lawrence Bart., Burford, Surrey.

Orchids, and especially the warmer-growing kinds, appear to thoroughly appreciate the extra sun heat we are now having. The Dendrobiums are growing fast, and roots have become plentiful. These plants now require plenty of root moisture until growth is fully completed, and if the foliage is well syringed underneath several times during the hottest part of the day, insect pests will be kept in check, and growth greatly assisted. Such plants as Catasetum, Cycnoches, and Mormodes, that are suspended close up to the roof glass, dry very quickly at the root, and therefore, as many of them are producing flower spikes in conjunction with the young growths, the plants should be carefully examined every morning. It is not advisable to spray this section of Orchids overhead, the growths being very tender. The deciduous Calanthes should by this time have filled their pots with new roots, and copious waterings must be applied each time a plant becomes dry. Such plants as Aerides, Vandas, Saccolabiums, Renantheras, Sarcanthus, &c., which do not possess pseudo-bulbs, and are potted only in crocks and sphagnum-moss, should be watered often enough to keep the moss on the surface in a growing condition. The Phalænopsis must be very carefully watered at all times, as their leaves are apt to become spotted and diseased if saturation of the rooting material is maintained for any length of time. Their top-dressing of growing sphagnum-moss should be allowed to dry till it becomes of a whitish-green colour before water is given, and then it should be very lightly sprinkled with a fine-rose watering-can, or the syringe which is generally advocated for spraying purposes. When affording water to Phalænopsis, it is better practice to sprinkle the roots around the sides of the basket or pan than to pour water in close proximity to the collar of the plant. Well-rooted plants of the various Cypripediums may be given almost any amount of water whenever they appear to be dry, and they delight in a gentle spraying overhead, both in the morning and at closing time in the afternoon. Habenaria pusila (militaris), H. carnea, H. Susannæ, &c., that have their growths now well advanced should be raised well up to the roof of glass, and the plants must be copiously supplied with moisture until the flowers open. H. rhodocheila just starting into growth should be repotted at once, and be treated as advised for its congeners in a former Calendar. In fine weather, when the nights are warm, there is no need to use much fire heat in either division. Even in the East Indian house the pipes should feel only moderately warm at night. Admit air freely through the top ventilators during the day, but close them early enough in the afternoon to allow the sun to raise the atmospheric temperature to between 80° and 90°. Damp well between the pots, under the stages, &c., so as to get the house thoroughly charged with moisture. During the evening the top ventilators may be slightly opened again, leaving a "chink" of air on through the night.

In the cool house such plants as Odontoglossum Rossii, O. Cervantesi, O. Madrense, O. Duvivierianum, O. Oerstedii, O. Humeanum, O. aspersum, O. nebulosum, O. uro. Skinneri, O. Bictonense, and O. cordatum are starting to grow, and as the young growths will soon produce new roots they may be re-potted at once. The same remarks are applicable to Cochlioda Noetzliana, C. vulcanica, and C. sanguinea. The stronger growing varieties as O. nebulosum should be grown in pots, but the dwarf kinds are best suspended well up to the roof glass in the ordinary flower pot or shallow Orchid pans. Good drainage is essential, and the potting mixture should be of peat and sphagnum-moss in equal ratios, pressing this moderately firm about the plants. Keep the surface of the compost well supplied with water until growth is completed, when moisture should be slightly diminished, but immediately the flower spikes appear increase the quantity. This house should be freely ventilated at all hours. Keep the paths, stages, &c., damp, and see that the plants are thoroughly shaded from sunshine.

PLANTS UNDER GLASS.

By B. Cromwell, Gardener to T. Sutton Timmis, Esq., Cleveley, Allerton, Liverpool.

Nepenthes.—Any plants that have been allowed to grow up on a single stem should be cut down to within 2 or 3 inches of the base, for they will not pitcher freely in this condition. If the tops of the shoots are pinched out every time three or four leaves are made, pitchers will form freely on the young growths. A little fresh sphagnum-moss, with some fibrous peat mixed with it, will form a good compost for top-dressing the baskets. Keep a sharp look-out for thrips and scale, for these are capable of quickly destroying the foliage.

Marguerites.—Plants which have been cut back and are intended to produce cuttings should be closely watched for the leaf-mining grub. Frequent spraying with the XL-All insecticide will act as a deterrent to the fly (which is now on the wing) laying its eggs on the young leaves, and by such timely attention much anxiety in growing these plants may be averted. When once the maggot is in the leaf it is most difficult to destroy without injury to the plants. Fumigation with the XL-All vaporiser has a wonderful effect in checking the progress of this pest.

The Stove.—Specimen plants in flower of Clerodendron, Ixora, Bougainvillea, Stephanotis, Allamandas, and Anthuriums may now with safety be transferred to the corridor or conservatory and allowed more sunshine and ventilation, which will the better help to ripen their growths. Care in the application of water, both in regard to quantity supplied and to its temperature, will be necessary while the plants are retained in the cooler and more ventilated structure. Increase the ventilation in the stove and extend the time of closing to 4 p.m. on fine days; at the same time gradually reduce the shading from the present time onward, as the thorough ripening of the wood is essential if free flowering specimens are desired. This applies especially to specimens that are planted out in the borders and trained over the roof.

Chrysanthemums in pots will soon be showing their flower buds, and in this district growers will be on the alert to secure the buds shown from the present time until the first week in September. The plants, having filled their pots with roots, would derive much benefit from light applications of a fertiliser, as these would induce increased root action just at the time when the buds are forming. It is advisable to take notes of the dates on which buds are "taken" (selected) of the newer varieties for future guidance. Keep the plants perfectly free from insects, otherwise many of the buds will be deformed. A light spraying with an insecticide

once a week will ensure cleanliness, and earwigs, which are usually so troublesome, will not so readily take up their quarters on the plants.

Bouvardias which have been planted out in frames will require a few small stakes and ties to keep them in their places. A little weak liquid manure may be afforded the plants about twice a week if they are not making gross wood, which is sometimes the case with old plants when planted out.

Richardias (*Callas*) *in pots.*—These will again be growing freely, and any that require repotting should have immediate attention, so that the young roots may have the benefit of the new compost, and the vigour of the plants be maintained. The early flowering of Richardias will much depend on the liberal treatment the plants have received in the early stages of growth. Good turfy loam, used in a rough state, with dried cow manure and coarse sand, is the best compost for these useful plants. Afford an abundant supply of water to the roots of plants growing in trenches.

FRUITS UNDER GLASS.

By T. W. Birkinshaw, Gardener to Lt.-Col. Sir Chas. Hamilton, Bart., Hatley Park, Bedfordshire.

Peaches and Nectarines.—Now that the fruit is all gathered from the early house, and this season's bearing wood has been cut out from the trees, abundance of air should be admitted during night and day. Continue to use the syringe as a prevention against insects, and keep the borders well supplied with water, alternating this with an occasional dose of weak liquid manure. It may be necessary in some cases to bring trees that are growing on the walls outside into the forcing houses. If such trees are planted in the borders, make an incision in the ground with a spade, commencing about 2 feet from the stem of the trees. This operation will cause the trees to make more fibrous roots, and thus be in a better condition for removing later on.

Late Houses.—Where fruit is required as late as possible, the houses should be liberally ventilated so that the atmospheric temperature will be kept comparatively low both day and night, but without causing cold draughts. Afford abundance of water and liquid manure to the roots during the second swelling of the fruit, and syringe the trees early in the morning before the sun shines fully on the foliage, and again soon enough in the afternoon, for the leaves to become dry again before night. Cut out to one leaf all sub-laterals as they appear, and expose the fruits well above the foliage, so that they may receive the benefit of the sun. If the last thinning of the fruit has not been completed, it should have immediate attention. Young trees planted in new borders usually make very strong and vigorous growths, therefore the strongest shoots should be stopped in order to obtain a balance over the whole tree.

Houses affording Ripe Fruit will require to have a little air left on at night. Gather the fruits very carefully as they approach ripeness and place them in boxes lined with cotton wadding, putting them in the fruit room. By adopting this method they may be kept fresh for several days. All bruised or undersized fruits can be used up in the kitchen. The trees should be carefully examined occasionally to see that the ties are not cutting into the bark; this would cause "gumming."

Peach Crimson Galande.—This is a splendid variety for growing in the second early house. The fruits are of a good size, finely formed, and beautiful in colour. In order to send it to the table in perfect condition, it should be gathered a little before it is ripe and kept for a few days, which will improve its flavour.

Late Melons.—Where these delicious fruits are required late in the season, the plants should be put into their fruiting quarters at once. A small house should be set apart for them where a night temperature of not less than 65° can be maintained when the days become shorter and colder. It is necessary at this date to have strong, sturdy plants to put out, so that they may make an uninterrupted growth from the start to finish. The plants may in some localities require a thin shade until they get established. Two or three fruits to each plant will be ample for this late batch. Cut out any side laterals that are not required for fruiting.

THE FLOWER GARDEN.

By Hugh A. Pettigrew, Gardener to the Earl of Plymouth, St. Fagan's Castle, Glamorganshire.

Time for Note-taking.—The present is an appropriate time, when the flower garden is resplendent with a blaze of colour, and the majority of plants in borders and beds are appearing to their best advantage, to make observations on the attractiveness or defects in the different subjects; to record opinions on novelties; to assign positions for special plants, and at the same time to note the harmony of colours of particular flowers when in proximity to one another. If a re-arrangement of herbaceous plants in the autumn is contemplated, or an improvement in the annual flower border next spring, notes taken now, with the plants and colours of flowers in front of one, will greatly facilitate the work when actually taken in hand. There are plants in the borders which, because of the brevity of their flowering period, or because of their blooming later or earlier than their companions, or their habit of growth is disappointing, must needs be eliminated to enhance the attractiveness of the border. Now is the time to make note of these, and decide on their substitution. The same is applicable to the formation of new ideas and work, insofar as it refers to flowers and colour, as obviously in planning new features in the garden it is so much easier to design and picture the effect and judge of its success, when the actual colours of materials are in evidence before one for reference and comparison, than if left until necessary to depend entirely to the retentiveness of the memory.

THE KITCHEN GARDEN.

By J. Gibson, Gardener to His Grace the Duke of Portland, Welbeck Abbey, Notts.

Winter Onions.—The end of the first week in August is a very good time to sow for this crop. At any earlier date there is always the chance of a large proportion running to seed, and, if sown much later, the plants do not become sufficiently large to be able to survive severe weather in winter. Sow the seeds on soil that has been trenched and liberally manured. Make the surface moderately firm when sowing the seeds, so that the roots will not ramble quickly and cause growth of a too robust and soft nature. Some of the varieties usually sown in the spring are very suitable to sow at this date, especially Sutton's Al and Perfection. Ailsa Craig, however, is not so reliable, owing to its extreme liability to run to seed. Of the well-known varieties, Giant Lemon Rocca is one of the best, and for a variety to mature quickly Sutton's White Leviathan is the best I have tried.

Cauliflowers.—At this season there is much trouble to get the early autumn varieties to "turn in" with that purity of curd that is so essential in a good "head." The lack of moisture in the soil and air, and the presence of much sunshine seem to be the causes. The plants should therefore be afforded copious supplies of water, both overhead and at the roots, tying also the leaves over the curds as soon as the latter begin to form. When they are large enough for use in the kitchen pull them up and store them in a cool, moist place, and if they are not required immediately they will keep good for a week or ten days, if the decaying leafage is taken off before it damages the curd. Loosen the surface soil between young plants, and if they are growing in a windswept position earth up the stems to prevent the plants suffering damage through "rocking" by the wind. Plant out any seedlings of early varieties that may be at hand; they will furnish useful "heads" before winter sets in.

Mushrooms.—The collecting of material for the making of beds to yield an early autumn supply indoors should not be further delayed. Daily gathering from the stables is much better than having it in quantity when it has had all its good properties spoiled by exposure to the weather. Add to the droppings as they become dry some good soil, from an old pasture land for preference. In the meantime the Mushroom house should be put in order, and any necessary repairs made to the beds or stages. Let the walls be limewashed. Early beds should be made on the ground level when possible, as this is cooler than the stages.

Tomatos.—Plants growing out of doors should have the tips taken out of the leaders just above a truss of blossom. There is no gain in letting the growth at the tip proceed further, as the fruits which set late in the autumn would not ripen. Keep all side growths rigidly pinched off, and if the plants are well set with fruits, liquid manure would help them materially. Sow seeds for raising plants to fruit in winter if this has not been already done.

Herbs.—Many herbs will require to be cut and stored from week to week. Select a dry day for doing this. Gradually harden the herbs before hanging them up in a freely ventilated store-room. Label all the bunches correctly, so that anyone may collect herbs without making mistakes. Encourage young plants to make growth by affording them water in dry weather.

THE HARDY FRUIT GARDEN.

By W. A. Cook, Gardener to Sir Edmund G. Loder, Bart., Leonardslee, Sussex.

Raspberries.—Lose no time in cutting down the old canes to the ground level, so that the energy of the plants may be solely devoted to the young growths that will furnish the crop next season. If it is the practice to train the young canes to strained wires or a trellis, let them be tied up, cutting away any weak shoots. If stakes are used, leave about four to six canes to each stake, and tie them up loosely, so that the air may easily circulate amongst the leaves. Clear the ground of any weeds, and hoe the surface lightly. The roots will require to be kept as moist as possible.

Vines on Buildings, Walls, etc., should have the leaders nailed in shapely, and the laterals cut back with a sharp knife to three or four leaves; allow room for each leaf to develop, and expose the fruit to the light. Syringe the plants with sulphide of potassium [½ oz. to the gallon of water, avoiding the paint which would be discoloured] to prevent mildew, and where it is necessary to afford the roots liquid manure.

Strawberry Beds.—Old plants may now be destroyed if not required to supply further runners. The supply of runners should have been obtained by this time, except perhaps in the most northern counties. Old plants should be raised with a digging fork (not cut off), and taken to the fire heap. The ground will be serviceable for a crop of Broccoli after it has been hoed and cleansed. Clean other Strawberry plantations and remove runners from the plants. Forced Strawberry plants put out early in the season should be kept clean and free from runners, and any flower-spikes showing should have the flowers thinned out, leaving only a few of the strongest, which will then produce serviceable fruits later on. Perpetual fruiting varieties of the St. Joseph and Alpine class should be freely supplied with liquid nourishment. They will presently provide an agreeable addition to the dessert.

Loganberry and Varieties of Rubus.—These are now bearing profusely, and should be supplied with water should the weather be dry. Thin out the shoots similar to Raspberries, and lightly secure those remaining to the columns by tarred string.

Wasps.—Keep a sharp look-out for these, and trap any that can be caught. Hunt for nests, and destroy them without delay.

Watering.—Keep all fruit trees supplied with moisture, especially those that are bearing heavy crops. Peach trees that have ripened a crop should be syringed daily, using occasionally some insecticide.

Espalier-trained Apples.—This method of growing Apples is capable of producing good fruits, and an abundance of them. These should now be finally "summer pruned," if it is not already done. Tie the leading shoots in to the wire or other supports, and if the trees are growing on the edge of vegetable quarters they may need extra nourishment. The fruits on the upper side of the branches of espalier trees usually gain a very high colour, and are easily protected from the birds in dry weather. Early varieties succeed well grown in this particular style.

General work.—This will include the watering and syringing of trees during hot weather. Spray under the foliage as a good preventive of red spider; tie and nail growths to the wall or fence. Protect fruit by netting it if birds are numerous. Prepare nets that have been used upon Strawberry and Raspberry plantations to be stored away dry, labelling each one with its size, &c. Keep the fruit room cool, dry, and well ventilated.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, *as well as specimens and plants for naming, should be addressed to the* **EDITOR, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but left as a guarantee of good faith.*

Special Notice to Correspondents.—*The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.*

Illustrations.—*The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, etc., but he cannot be responsible for loss or injury.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.*

Local News.—*Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matter which it is desirable to bring under the notice of horticulturists.*

APPOINTMENTS FOR AUGUST.

TUESDAY,	Aug. 7	Leicester Hort. Sh. in Abbey Park (2 days).
WEDNESDAY,	Aug. 8	Roy. Hort. Soc. of Ireland's Autumn Sh.
FRIDAY,	Aug. 10	Roy. Bot. Soc. (anniversary meeting). Huddersfield Hort. Sh. (2 days).
SATURDAY,	Aug. 11	Dutch Gard. Soc. meets.
TUESDAY,	Aug. 14	Roy. Hort. Soc. Comm. meet. Exmouth Hort. Sh. (2 days).
WEDNESDAY,	Aug. 15	Taunton Deane Hort. Sh. (2 days) Wilts Hort. Sh. at Salisbury.
THURSDAY,	Aug. 16	Manchester & North of England Orchid Soc. meet.
SATURDAY,	Aug. 18	Sheffield Hort. Sh. German Gardeners' Soc. meet.
TUESDAY,	Aug. 21	Brighton Hort. Sh. (2 days).
WEDNESDAY,	Aug. 22	Shropshire Hort. Soc. Sh. at Shrewsbury (2 days). Harpenden Hort. Sh.
THURSDAY,	Aug. 23	Roy. Hort. Soc. of Aberdeen Exh. (3 days).
FRIDAY,	Aug. 24	Devon & Exeter Hort. Soc. Sh.
SATURDAY,	Aug. 25	Dutch Gardeners' Soc. meet.
TUESDAY,	Aug. 28	Roy. Hort. Soc. Comm. meet.
WEDNESDAY,	Aug. 29	Bath Floral Fete (2 days).

AVERAGE TEMPERATURE for the ensuing week, deduced from observations of Forty-three Years at Chiswick—63·2°

ACTUAL TEMPERATURES:—

PROVINCES.—*Wednesday, August* 1 (6 P.M.): Max. 71° Guildford; Min. 62° Land's End.

The Hybridisation Conference. The Conference which the R.H.S. has this week instituted, and which is in progress as these pages are passing through the press, may be looked on as a "sign of the times." It is one which reflects credit on the old Society and shows that its directors are conscious of the responsibilities that rest upon them, and are desirous not to limit their energies to the holding of exhibitions and the distribution of medals. Darwin's "Origin of Species," and more particularly his "Animals and Plants under Domestication," in the preparation of which he availed himself so largely of the observations of cultivators, drew special attention to the subject of heredity. For a time it seemed as it this were a subject that could not be studied with much chance of success. The explanation of the various phenomena seemed to be beyond our grasp. There was, as Mr. Bateson said, more of mystery than of order. But conditions have changed. Mr. Bateson, the President of the Conference sitting this week, rescued Mendel's observations from oblivion; De Vries worked in the same direction; Correns and Tschermak have repeated Mendel's experiments. In our own country, besides Bateson, Hurst and Biffen, Miss Sanders and many others are now engaged in reducing to order and symmetry facts and observations which were previously in a more or less chaotic condition. Vagueness and conjecture are giving place to exact numerical proportion, according to the "law" of segregation, to the great advantage of physiological science, and ultimately assuredly to the great benefit of the practitioner. This great change has been brought about, not merely by careful observation and comparison, but by actual experiment. The student of what it is proposed to call "genetics," if he is to make progress, must not rely on text-books or the teachings of a master; he must not be content with the laborious comparison of dried specimens in the herbarium, or the more or less casual inspection of plants in the trial-grounds, he must conduct carefully-planned experiments, and, by their aid, he will obtain answers to his questions which can be supplied by no other means.

This is the work for the coming generation in particular. Observers of a former generation will have much to unlearn, they will find it difficult to shake off old routine and divest themselves of old prejudices. A battle like that between the "artificial and the natural system" will have to be fought under new circumstances, and, judging from the past, there can be no doubt as to the result. The natural system is ideally perfect, but, in practice, an artificial system is still, and must always be, a necessity. Whatever advance may be made by the Mendelians, and the students of cytology, however widened may be our conception of "species" and "varieties," in practice we shall still have to trust in the judgment and discrimination of the systematic botanist. There will be room for both classes of observers and workers, and each will derive assistance from the other. Push analysis as far as we may, synthesis will still be needed to co-ordinate results and make them intelligible to students in general. The old Linnean "species" are now recognised as too comprehensive to be taken as units (unless purely for convenience sake). How, then, are we to get at the real units, if such there be? The answer is, by microscopical analysis of the nucleus of the cell and its "chromosomes," but especially by experimental cultivation and rigorous determination of genealogical position. Take a seed from a self-fertilised plant and isolate the seedling. When in time it produces flowers, screen them from all possible advent of pollen from other sources. By a continuance of this practice of self-fertilisation for several generations under like conditions and by eliminating all "rogues," we may hope to obtain a "specific" form which will perpetuate, without change, its characters we shall then arrive at the elementary species. In this way, M. L. Blaringhem, who has a most valuable paper in the April number of the "Journal de la Société Nationale d'Horticulture," has obtained at least eight perfectly distinct forms from the barley, Hordeum distichum of Linnæus. Hugo de Vries, in demonstrating by experiment the origin of what are called "elementary species," has supplied the method of discovering new types from which improved and stable forms may be procured. M. de Vries has also shown the strong tendency there is for certain abnormal forms to become hereditary. Amongst other cases he cites the case of the twisted teasel. In ninety-five per cent. of his seedlings he has observed the twisted conditions to be reproduced. Here we may remark that these results do not always occur. Several years since Professor de Vries kindly supplied us with seeds of his twisted variety. These seeds were sown, but no twist was observed in the offspring. Seeds come up year by year in our garden, the descendants from those originally sent by M. de Vries, but in no single instance has a twist of any kind been observed, except in one case, last year, where, after repeated pinchings and other mal-treatment, we induced a slight twist in one of the side branches of one of the specimens operated on. In a similar manner M. de Vries has observed the splitting-up of the "species" Œnothera Lamarckiana into nine distinct "mutations," or sports, these sports having all the attributes of species as regards constancy and hereditary transmission. Of course, there is no doubt whatever as to the correctness of M. de Vries' observations which have been confirmed by other observers, but he has been fortunate; such mutations are not always to be found in Œnothera. No such change has been witnessed by others, and we have had opportunities of seeing them, and have watched for them for several years. In like manner we observed, some years in succession, a very large patch of Impatiens Roylei in a deserted garden. The plant had, in fact, usurped the whole space, but no "mutations" were visible. Negative evidence of this kind is, of course, unimportant, save as showing that "mutations" of this kind only occur under certain circumstances, which are at present mysterious.

As to Mendel's experiments, they are, of course, the subject of remark in Mr. Bateson's address and in other papers. We would only remark that one very important point brought out is that in hybridisation there is juxtaposition but no actual blending or fusion of parental characters; the male cells remain unaffected, the female cells are unchanged, though some "characters" may become "dominant," others latent or "recessive," till, by a so-called process of reversion, the latent character may reappear.

The subject is too extensive and complicated for us to deal with in the course of an article. The papers read at the Conference were so numerous, and in many cases so highly technical, that we can do little more than enumerate them. The reader has before him in the present issue the text of Mr. Bateson's lucid summary, and we look forward with great interest to the volume in which the R.H.S. will no doubt enshrine the full proceedings of this Conference. That these somewhat recondite researches will lead to important practical results is certain. M. Blaringhem, in support of his view, concludes his paper with a reference to the "marvellous" progress in the improvement of agricultural plants effected in the experimental grounds at Svalöj, in Sweden, by Dr. N. Hj. Nilsson. In this matter, as in most others, it is researches, made originally for purely scientific purposes, that turn out in the end to be far

the most fruitful in practical results, and hence, whilst technical schools are necessary, indeed, indispensable establishments for original research are of even greater importance, albeit their value to the practical man may not be immediately apparent.

Next week we shall give a report of the proceedings after these pages had gone to press. In the meantime we may congratulate the Society on the large number of distinguished scientists that have responded to their invitation, and we hope that they will be pleased with their reception.

National Amateur Gardeners' Association.—A lecture on "Violas," by Mr. D. B. Crane, and exhibition of flowers, &c., will take place at Winchester House, Old Broad Street, E.C., on August 7, at 7 p.m.

The Board of Agriculture.—Mr. Robert Henry Rew has been appointed to be an assistant secretary to the Board of Agriculture and Fisheries, in the place of Major P. G. Craigie, C.B., who retires from the public service as from August 1.

The late William Farrer.—Mr. William Farrer, whose death occurred last April, was best known to the agricultural world for his experiments with Wheat. According to the *Agricultural Gazette of New South Wales*: "For the past twenty years Farrer had been engaged on the self-imposed task of the improvement of Wheats, and though his aims were more immediately directed towards the satisfaction of local requirements, the thoroughness of his methods and the broad scope of his investigations have been productive of results of value to every Wheat-producing country in the world. The problem which he set himself was the systematic improvement of Wheat by cross-breeding and selection, particularly in the direction of producing types which should resist our two principal scourges—rust and drought, and in the maintenance of a high milling standard, more especially in the production of strong flour Wheats." The result of his endeavours was the production of cross-breds superior for the purposes required of them to any varieties formerly in use, not merely in his adopted country, but throughout the world.

M. Ed. Andre.—It is with great concern that we hear of the very serious illness of our friend and colleague the Editor of the *Revue Horticole*.

Le Bambou.—The July number of this periodical published by M. Jean Houzeau de Lehaie, Ermitage, Mons, Belgique, contains among other matter of interest to Bamboo cultivators a complete list of all the species cultivated in Europe, together with their synonyms, and indications of their native country.

The Oldest Living Tree.—A correspondent of the *Times* writes:—"It is difficult to realise, in these days of scepticism and higher criticism, that it is possible to see and handle portions of the branches of a tree under the shade of which both St. Luke and St. Paul, according to Dean Farrar, probably rested. In the island of Cos, in the Ægean Sea, there stands, jealously guarded, a huge plane tree, measuring nearly 18 yards in circumference. It is surrounded by a podium, or raised platform, breast high, doubtless built to support the trunk of the tree after it had become hollow and weak from age. The lower branches are still well preserved, and have been shored up by pieces of antique columns, over the upper ends of which the branches have grown like caps in consequence of the pressure of their own weight. Close by the tree is a solid marble seat, which is said to be the chair of Hippocrates, the father of medicine, and it is supposed that he taught the art of healing from that seat. He was born at Cos 460 B.C. This gives a clue to the age of the celebrated plane tree, which must be considerably more than 2,000 years old. Dr. Edward Clapton, formerly physician at St. Thomas's Hospital, whose devotion to archæology is well known, sent an agent a year or two ago to procure some fragments of the tree. This was done, but at considerable risk, as the Sultan, who attaches great importance to its preservation, has given strict orders that no one is to touch the tree, which is therefore guarded day and night. The specimens which Dr. Clapton obtained have now been generously handed over to the Royal College of Surgeons, where they will be displayed in the museum. They consist of two pieces of branch, a bundle of twigs from the branches, and a small box of leaves and round button-like catkins of the plane tree." [There can be no doubt as to the antiquity of this tree, but we fail to recognise any direct evidence of the extreme age attributed to it.]

Country Life in France.—We note the publication, from 3, Rue de Navarin, Paris, of a paper somewhat on the lines of our contemporary, *Country Life*. *Villas et Maisons de Campagne* deals also with gardens pleasurable and profitable, with the farm and orchard, and with country industries, sports, and interests in general. The first number is interesting, and we wish success to the venture. There are plenty of illustrations from photographs, as well as some working plans in the new paper, the sub-title of which includes the word "home," for which, as is well known, neither "villa" nor "maison" is an exact translation.

Economic Meteorology and the Fruit Crops. Mr. A. O. Walker, F.L.S., of Ulcombe, Kent, writes us as follows:—"In your last issue (p. 70) you remark on the 'neglect of fruit cultivators in the matter of raising late-flowering varieties and the selection of sheltered localities.' As regards the first of these questions, I do not consider it of much importance, for frosts and cold winds have no fixed time, and the best crop of Cherries I had this year was on the earliest flowering variety, the amount of blossom on all the trees being about the same. But it is surprising that no organised effort has been made to ascertain and record the situations where the fruit crops suffer least from adverse weather influences. In August, 1905, I called attention to this question, and to the great difference between the climate of this place and Maidstone (*Nature*, vol. lxxii., p. 342). The question is a difficult one, and complicated by conditions of soil, exposure to winds, methods of cultivation, &c., but its great economical importance, where the fruit industry is as large and increasing as it is in Kent, surely warrants some expenditure on the part of the county authorities. The appointment of two or three county agricultural inspectors, who would report every year on the climatic conditions at the blossom time, and the state of the crop in the summer, the good and bad localities being indicated exactly on the 6-inch Ordnance map, with the co-operation of the fruit growers, should in time lead to a practical knowledge of the best sites for orchards. And the duties of the inspectors should include enquiry into all kinds of insect and fungus pests, for which they are sadly needed. They might be assisted by an association of economic meteorology for the county, who could supply the meteorological data. The South Eastern Counties' Agricultural College at Wye might be the scientific centre of the movement, in the same manner as Liverpool University has been for the Lancashire Sea Fisheries. I am quite aware of the danger of suggesting any addition to the rates, but I fancy the salary of two or three inspectors (who must, however, be thoroughly competent or they will be worse than useless) would only amount to a small fraction of 1d. in the £, while the saving in preventing the planting of orchards in such unsuitable positions as in the case of many in this neighbourhood would eventually be enormous."

FLORISTS' FLOWERS.

THE RUNNING OF THE COLOURS IN CARNATIONS.

There were not many examples of run flowers in the classes for Bizarres seen at the recent show of the National Carnation and Picotee Society. So far as my experiences go the reasons for the "running" of the colours in Carnations are not to be ascribed to anything connected with the cultivation of the plants, but to the natural sportive nature of the Carnation. A variety may run in one year, and the next year the flowers will be quite clear and finely marked, and the chances of clean blooms are equal whether layers are taken from plants that have produced run flowers or from clean ones. The chief points to be observed in cultivating these florists' varieties are: to avoid the use of crude or excessive quantities of manure in the compost; to make use of pasture loam that has been one year in stock; not deprived of its fibre, and where the loam form two-thirds of the whole. If the loam be of a heavy nature, it may be necessary to add some road grit or sharp sand, not otherwise, for the fibre of the grasses and other plants of which the sward consists will afford sufficient porosity.

Any substance added to the compost which would engender excessive vigour to the plants should be avoided. Seeing that moisture is more to be guarded against than frost, I would advise the raising of the beds above the general ground level. For the same reason the plants wintered in pots in cold frames should be plunged in coal ashes of sufficient depth to make sure of the rapid passage of water from the pots. *F. M.*

KEW NOTES.

THE GREENHOUSE.

Some of the species of Isoloma and Tydæa (the latter are now included under Isoloma by botanists) hybridise freely, and there are now a large number of interesting hybrids in this house (No. 4). A group of a dozen plants is to be seen here. The heavily spotted flowers are very freely produced, and grown several together in 6- or 7-inch pots the plants form nice specimens. The long, tubular, scarlet flowers of Gesnera cardinalis imantha are very effective, and the plants are used here as a groundwork for red and white Balsams. Baskets of Achimenes suspended from the roof appear more at home than when growing in pots. Especially good are A. coccinea and A. longiflora var. macrantha. The pure-white flowers of A. (Dolichodenia) tubiflora are sweetly perfumed. It is a distinct plant, 2 feet high, with four to ten flowers on a panicle. Saintpaulia ionantha, the African Violet, is now to be had in varying shades of colour, from white to deep purple. It is very easy to raise a stock of any particular colour desired, as pieces of the leaves make roots readily if laid on fibre, or other similar material, in a moist house. Streptocarpus and seedling Gloxinias are also flowering freely. The large and handsome flowers of Lilium sulphureum cannot fail to attract attention growing in the beds. A number of L. philippinense in 3½ and 5-inch pots look almost as if the white trumpet flower is too heavy for the slender stem and elegant foliage. L. tigrinum var. pseudotigrinum is also flowering in pots, and planted out in one of the beds. Mimosa pudica, the sensitive plant, is very popular with visitors. The small globose pink flowers and pinnate leaves are ornamental, dotted amongst plants with brilliant flowers. The varieties of Salvia splendens are now numerous, and can be had in flower almost the whole year round. The hybrid Statice profusa (S. puberula × S. Hol-

fordii) lasts a long time in flower. Francoas make useful subjects for greenhouse decoration. If the house is a small one, plants can be raised from seeds and obtained in flower in six to nine months. For larger greenhouses the plants may be grown on for several years. Those at present in flower vary from one and a half to three years old. The racemes of flowers are freely produced, and vary in colour from white to deep pink. They are hybrids of the three species—F. appendiculata, F. ramosa, and F. sonchifolia. The variegated Lily of the Valley tree, Clethra arborea variegata, is useful as a foliage and a flowering plant. The white flowers are abundant at the ends of the shoots. In the warmer parts of the country it succeeds in the open.

Standard plants of varying kinds are always useful for dotting amongst groups of low growing plants. By this method the flowers of some plants are seen to much greater advantage. This is especially so with Abutilons. The hanging, bell-shaped flowers can be seen much better than when grown as bush plants. Other plants grown in this way are Fuchsias, Acers, Zonal Pelargoniums, and Heliotropes.

The Glory Pea of Australia, Clianthus Dampieri, with its bright red and black flowers, is conspicuous both in baskets suspended from the roof and in pots. Little success is obtained by growing the plant on its own roots. All the plants flowering here were grafted on Colutea arborescens in the seedling stage. *D. D.*

SOCIETY FOR HORTICULTURAL SCIENCE.

SUMMARY OF PAPERS READ AT THE CORNELL MEETING, JUNE 27-28.

President L. H. BAILEY's address was on "The Field for Experiment in Horticulture." Prof. JOHN CRAIG presented a paper on "Plant Growing by Artificial Light." Prof. LAZENBY spoke on "Plant-Growing under Different Coloured Cloths." Unfortunately, these papers have not yet come into the reviewer's hands, and hence abstracts of them cannot be given at this time.

Mr. W. T. MACOUN spoke on "The Relation of Winter Apples to the Hardiness of the Tree." To withstand a test winter in Ottawa, a tree or shrub must ripen its wood early. Winter killing is liable to be more severe after a season when the growth has been strong than when it has been short. The more moderate the climate where a variety originates, the less resistant is it to the winter killing. The hardiest two varieties of Apples are those that have originated in Russia and are summer or autumn varieties. This is because these ripen their wood most thoroughly, whereas winter varieties continue growth later in the season. Unless the fruit of a variety reaches a certain, but, as yet, undetermined, stage of development every season a certain time before it has to be picked, owing to danger from frost, that variety is not a safe one to plant. The basis for the production of the desired winter Apple for the north should be a variety which has withstood test winters in a similar climate, and is also the latest keeper of such varieties.

Prof. WILLIAM STUART presented a general discussion of the use of anæsthetics in the forcing of plants, and summarised his own experiments with Rhubarb.

The experience of a number of investigators indicates that some classes of plants will stand larger doses of anæsthetics than others. As a rule, these doses vary from 7 to 15 c.c. per cubic foot of air space. The time of treatment varies with the season of the year, the class of plants and the temperature at time of treatment. As a rule this variation is from 24 to 72 hours. Etherisation of rhubarb plants for winter forcing results in an increased yield.

Freezing, at least early in the season, is a necessary process. Etherisation does not seem to perform the same function as freezing. Actual freezing for late forcing may not be necessary.

In a paper on "Pollination Methods," Prof. S. W. FLETCHER presented a "symposium" of his own experience, and that of a considerable number of other plant-breeders. The ideal time to emasculate blossoms is as late as possible before the anthers dehisce, but it may be done when the buds are still quite small. If complete accuracy is not essential, and when working on blossoms that do not mature stamens and pistils simultaneously, the blossoms need not be emasculated. In crossing, select mature trees of moderate growth and perfectly sound. On such trees select buds borne high on the outside of the tree on well-nourished branches on the side of the tree opposite from the direction of severe prevailing winds. As to the instruments for emasculating, in the majority of cases a small scalpel is to be preferred, specially for the stone and pome fruits. As to the location of the cut, the general opinion is that it should be made at the insertion of the stamens above the nectary, though the author himself prefers to make it as high up as possible. The safest time to pollinate is near the beginning of the receptive condition of the pistils or perhaps twenty-four hours before. A receptive stigma usually glistens when it catches the sunlight, and in most fruits it is beginning to be slightly brownish.

Brush-pollinating is often most practicable when many blossoms must be pollinated in a short time. For our common trees, however, some workers use the thumb or forefinger. As to the percentage of successes seven pollinators of experience placed their averages variously at from 50 per cent. down.

"Some phases of pollination" were presented by Prof. N. O. BOOTH. The period during which fresh pollen is available for study may be lengthened by forcing twigs in the laboratory. If pollen is taken from the orchard at normal blooming season, it is advisable to take twigs with still unopened buds, and let them open indoors. This assures freedom from foreign pollen. Pollen of the same varieties differs greatly in germination when trees are grown under different conditions. Determinations of the percentage of the germinating pollen is an index to the capacity of such trees for self-pollination in such localities, and hence for plant in solid blocks. Very few Apple varieties have the pollen all good, and none, so far, all bad, most varieties showing different proportions of mixed forms. Pollen from the same tree may differ with the condition of the tree. Tompkins King and Esopus Spitzenburg have notably weak pollen, and are successfully raised only in neighbourhoods where conditions are favourable for pollen production. Varieties with particularly strong pollen, as Johnathan and Ralls, are of wide adaptation, and are often liable to overbear, the fruits being consequently under size.

Prof. FRED. W. CARD presented a "symposium" of experiences as to the advantages of double-working Apples on vigorous stock. The value of top-working to increase hardiness of stock in a trying climate is unquestioned. It markedly reduces injury from certain diseases. Northern Spy especially promises to reduce injury from the woolly aphis in the south. Weak-growing varieties are benefited by the practice. Early bearing can be promoted by top-working on a weak stock, although at the expense of productiveness and, doubtless, of longevity. But for ordinary varieties in favourable regions the advantages of top-working are outweighed by the disadvantages.

Mr. EARLE J. OWEN discussed the importance of selection in plant-breeding, citing several striking examples of its application.

Prof. L. C. CORBETT raised the query, What is to be the future application of the term horticulture? To the already recognised sub-divisions of horticultural interests in America, namely, Olericulture, Pomology, Floriculture, and landscape gardening, the author would add plant-breeding and plant-propagation. Under the latter heading is comprised nursery work and the increasing of annual plants from seed or from herbaceous cuttings.

Mr. H. J. EUSTACE gave an account of investigations on Apple decays in commercial cold storage. Several varieties were inoculated with black rot, brown rot, bitter rot, soft rot, or blue rot, and a species of Alternaria, and at once put in a cold storage under standard temperature conditions, that is, where the temperature was held constantly at 30 to 32 degrees F. At the end of two months none of these diseases had developed except the soft or blue rot. Later, when the inoculated fruit was taken out of storage, the other diseases also developed, showing that the low temperature of the cold storage simply retarded the fungi in their development, but did not destroy them. In another experiment, where the temperature ranged from 37 to 56 degrees, decays developed slowly, except the soft rot; but when the temperature ranged from 54 to 65½ degrees, all decays developed and in most cases very rapidly. Peaches similarly inoculated, and held in cold storage two weeks, had developed decays in about one half of the specimens.

Mr. H. P. GOULD described the recording Phenological date for pomological uses as has been carried on by the U.S. Department of Agriculture for several years past.

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

THE BEDDING IN BATTERSEA PARK.—There is much experimental work of value to the gardener carried on here every year by the superintendent, Mr. Rogers, this chiefly taking the form of new combinations of plants in the flower-beds, and as there are but few examples of geometrical parterres in the park, the comparative failure in good effect of a bed or two never mars the general effect. Such mischances are extremely rare, although some hazardous combinations and risky ventures are made. Nothing but praise can be meted out for the planting of the beds in the "sub-tropical" garden, which remains this year, as always, the showpiece of the whole. A noticeable innovation is the employment of tall plants for the middle area of a large bed with standard Heliotropes, Fuchsias, Solanum jasminoides, Plumbago capensis, and other tall-growing, graceful plants set out at regular distances apart amongst these; next to this, broad bands of dwarfer plants form a border 4, 5, and 6 feet in width, instead of one or two lines, as formerly was universal. As a finish there is usually an edging of one or two rows of quite dwarf things next to the turf. I will describe a capital example of one of these beds, which stands at the corner of the "sub-tropical" on the south-west side. The shape is roughly that of a heart or a bird with extended wings, and may measure 20 feet in width. The middle area is filled with a very tall and strong-growing intermediate Stock, having purple-coloured flowers, widely planted so as to grow to their fullest size, and now just touching each other; placed among these are standard Fuchsias having red flowers, and around this central area is a border 6 feet in width furnished not too thickly with tuberous rooted Begonias, then a broad band of pale blue Viola intermixed with Iresine Herbstii, the colours of the leaves of which make a not too violent contrast with the flowers of the Viola; and the back line consists of a variegated-leaved Pelargonium. Here and there, as relief points to the masses of floral display, are small groups of Kochia, the foliage now green, but which will change to claret-red as the season advances. There are several such beds, each planted in a dissimilar manner and all equally good in effect. It may be here remarked that Violas play a leading rôle in the park this year, being employed as the groundwork plant in some beds, edgings in others; and in the panel parterre, near the botanical garden, near the river, they are planted in oblong sections of about 20 feet in length, the varieties being arranged in opposite pairs. Considering the dryness and heat of the present summer and the steepness of the slope on which they are planted, these Violas are flowering abundantly and promising a rich display for a long time to come. Ivy-leaved Pelargoniums of the Mad. Crousse and Souvenir de C. Turner type are largely made use of in big beds, together with a setting of Violas in variety beneath them. These beds are very charming. Begonias of the semperflorens and floribunda types are much planted in the smaller beds, but tuberous rooted varieties are planted but tentatively, the soil or the air of the district being unfavourable to their well-being as a class of bedders. B. Count Zeppelin, having good-sized crimson-scarlet flowers, is very effective among varieties with fibrous roots. It grows to the height of about 1 foot and has a bushy habit of

growth. The various Palms have come forth from the winter quarters in excellent condition, and they are, together with Musas of species, and Dracænas, arranged so as to form a grade in the "sub-tropical" garden, each specimen being sunk into the turf. Of beds of succulent plants several were noted; the Agave Americana specimens, both green and variegated, being sunk as regards their pots and tubs to half their depth, and mounds then formed round them, these being carpeted with Echeverias, Sempervivums and other dwarf succulent plants. The arrangements adopted with these plants are the best that I have hitherto observed here. A little plant almost dropped out of cultivation, viz., Kœniga maritima, having a dwarf habit and abundant globular white flowers of long duration, is largely employed in small beds with good effect. *F. M.*

APPLE AND PEAR SCAB.—I have read with much interest the contribution on the Apple and Pear scab by Mr. E. S. Salmon in your issue of July 14, 1906. Having gone into the question, especially during the past three years, I beg leave to give the results of my investigations. It is, in my opinion, not an external, but an internal, disease. The cause is in the choice of stock used, the nature of the soil, and the mode of planting. I find the disease is more prevalent, in fact abundant, wherever the subsoil is chalk or of a chalky composition. A Pear tree planted in a soil where there is such a subsoil, and which has been grafted on the common Pear, takes the disease so soon as its roots come in contact with the soil which is chalky, whilst a Pear grafted on the Quince is, I find, always free from the disease, because its roots keep close to the surface. The same applies to the Apple worked upon the Crab; the roots descend, and the mineral properties contained in the soil (of a chalky nature) act upon the constitution of the tree as in the case of the Pear, and the tree becomes contaminated, whereas Apples worked upon the Paradise stock, whose roots keep near to the surface, are always free from the scab. If trees worked upon the common Pear or Crab stocks are desired, the best preventive of disease is to pave the bottom of the hole before planting the tree with slate, tile, or brick in a conical form, so that the water may not hang about the roots. Trees thus treated are kept free from the fungus for a very long time—it may be for several years. Outward washings with insecticides are, I am afraid, useless. The best preventive I know is to paint the infested branches with train oil. I find the disease does not spread from one tree to another through space. In these nurseries there are growing side by side Pears on the common Pear and on the Quince; the former are eaten up with scab; the latter are perfectly clean and healthy because their roots are not in contact with the chalky subsoil, which is the nature and character of the soils in this locality over a vast area. *John Smith, Salisbury.*

YELLOW AND RED RASPBERRIES.—I have a row of Raspberry canes in my garden; they have been in the same place for about six years, and during all that time the fruits have been red with the exception of two plants at the farther end, which were yellow. This year they are all yellow, and there is not a red one amongst them; there are about 45 roots in the row. *J. Pettitt, Corn and Seed Stores, Windsor.* [Assuming that no mistake has been made, the circumstances seem to indicate that the plants have sported. ED.]

HYBRID BELL-FLOWERS.—With reference to Mr. Jenkins' remarks on this subject appearing on p. 28, I may say that I was not aware of the existence of any doubt as to the parentage of Campanula × Hendersoni, and was likewise unaware that any other plants than C. carpatica and C. alliariæfolia had been cited as its progenitors. Mr. Jenkins' copy of the "earlier editions of Nicholson's Dictionary of Gardening" must differ somewhat from my own, as I see therein no such statement as is advanced to support the opinion stated on p. 28. What I do see is C. × Hendersoni placed as a sub-variety of C. carpatica, while the *Century Supplement* gives: "C. Hendersoni (Henderson's), a variety of C. carpatica." Judging from the following remarks appearing on p. 28, I should say that the plant known by me and grown generally by the trade as C. × Hendersoni is not known to Mr. Jenkins. "If, however, C. alliariæfolia is one of its parents, such important features as the hoary tomentum, the type of inflorescence, the form of the flowers, and much of the form, as well as the leaf substance have all been obliterated, which is unusual." But have they? I think not. For editorial inspection, I enclose dried leaves of:—1, C. alliariæfolia; 2, C. carpatica; 3, C. × Hendersoni; 4, C. × Fergusoni; 5, C. pyramidalis. It will be noted that the "hoary tomentum" is almost, if not quite, as marked a feature of the leaves of C. × Hendersoni as it is of C. alliariæfolia, while "the form as well as the leaf substance" have in no sense been "obliterated," but remain as visual evidence of direct relationship, especially when compared with the leaf of C. × Fergusoni (an acknowledged result of the contended parentage C. carpatica × C. pyramidalis), which is quite glabrous and of remarkably thin texture. *E. Horton, Neston, Cheshire.*

GOOSEBERRIES.—In the matter of Gooseberries the consumer has but little choice as regards varieties, the most abundant bearers being alone offered for sale, superior eating qualities being not thought worthy of consideration by market growers. There must be tons of this fruit disposed of weekly in the suburb in which I reside, but were I to ask my greengrocer to supply me with a dish of Red Champagne, Red Warrington, Farmer's Glory, Woodward's Whitesmith, Taylor's Bright Venus, Smiling Beauty, or Pitmaston Greengage, he would regard me as a most unreasonable person, a Gooseberry being to him simply a fruit without any distinctive quality either good or bad. Those I have named are what are called "dessert" varieties, and the first two and Bright Venus may be kept in good condition for two or three weeks after being fully ripe by matting up the bushes, and trained fanwise on a north wall, and protected from the birds, the fruit may be kept in good condition much longer. The variety Red Warrington is one of the best for jam, in this respect excelling the first named. Cheshire Lass has large oblong fruit, skin white, thin and downy, and ripening early. Whitesmith has fruit of a similar shape and colour to the last named variety, and the exposed berries when quite ripe assume a brown hue. It is one of the best flavoured Gooseberries extant. Yellow Champagne has small, almost globular, berries of a pale yellow colour and very hairy. It ripens a fortnight later than Early Sulphur, to which it bears great resemblance, and is finer flavoured. The whole of the above are old inhabitants of our gardens and still well worthy of being grown, as not being excelled by any of the new introductions, although some of these raised by Messrs. J. Veitch & Sons run them very close in flavour and thinness of the skin. *London Suburb.*

BROAD BEANS.—Whilst cordially agreeing with what your correspondent writes in the *Gardeners' Chronicle* last week concerning Broad Beans, I am surprised to find him ignoring the old Cluster variety and especially Beck's Green Gem, a variety of this. The latter is dwarf and bushy in habit, and a profuse bearer far exceeding in the number of the pods per plant any Longpod, Aqua Dulce, or Giant, and the Beans are small in size, as opposed to the large Green Windsor and the others named. Being dwarf, it is a suitable variety for small gardens, or for intercropping with other low-growing vegetables. The plant comes into bearing very early in the summer, and its only fault is the rapidity with which its seeds become aged and mealy, calling therefore for close picking, if tenderness in eating is a *desideratum*. It needs no "topping," like the taller Broad Beans, and if only for its earliness in coming into use, the variety is worthy of the notice of the cultivator, and the pleasant green colour of the Beans when cooked. *F.M.*

CAMPANULA × STANSFIELDI.—We enclose you herewith a photograph of our new hybrid Campanula [not suitable for reproduction, ED.], which the late Rev. Wolley Dod described as the best hybrid Campanula which has yet appeared. The history of this interesting hybrid is not well known. It originated in our nurseries at St. Luke's Road, Southport, some 12 years ago. Its appearance there is quite a mystery. It was quite apparent that the new arrival was different from anything in our collection which numbered some 50 species and varieties. As the plant began to develop and show its character it was quite distinct from anything we had then growing upon our place. The plant is somewhat a slow grower, and it was several years before it was introduced to the general public. Fortunately for the present stock of this plant a few were given to the late Mr. Wolley Dod. He at once planted it in his rock garden where the plant grew much better than it did at Southport, and in the course of a couple of years grew into fine plants which flowered abundantly. The flowers are borne upon thin wiry stems about 6 inches high; they are of a rich violet-purple colour, almost as deep as those of Campanula pulla. Upon the removal of our stock from St. Luke's Road to Kew, Southport, we lost the whole of this interesting hybrid Campanula. In the meantime the Rev. Wolley Dod's plants had grown well. He began to send a few notes both to the *Gardeners' Chronicle* and other papers mentioning my name as the raiser of this unique plant. Mr. Dod was of the opinion that it was a cross between Campanula carpatica, the pollen plant, and Campanula Waldsteiniana, and yet taking more of the character of Campanula Thommasiniana, a name not recognised in De Candolle *Monograph of Campanulas*, although it is a plant well known to Alpine plant growers, and quite distinct from C. Waldsteiniana. In the case of C. Tommasiniana the plant is of an extremely wiry character with pendant pale blue flowers, while those of Campanula Waldsteiniana are always erect and almost flat; both are extremely beautiful and graceful rock plants, and I believe I am right when I say that the late Mr. Wolley Dod had raised both plants from seeds which had ripened in his garden at Edge Hall. During a visit to Messrs. Isaac House's Nurseries at Westbury-on-Trym, I saw several clumps of this new hybrid Campanula. The plants were growing so strong and vigorous that I hardly knew the plants as grown in the south-west of England. It is a plant that delights in plenty of sunshine, and the plants growing at Westbury-on-Trym were doing much better than they do at Southport. The foliage, too, had taken on a new character not uncommon among hybrid Campanulas, namely, a yellowish colour like a well-known form of Campanula G. F. Wilson and also well known in Campanula Haylodgensis. *W. H. Stansfield, Kew Nurseries, Southport.*

Obituary.

ROBERT COCK.—We regret to have to record the death on Sunday last of Mr. Robert Cock, Instructor in Horticulture, Bee-keeping, and Poultry-keeping to the Staffordshire Education Committee. Mr. Cock was an occasional contributor to these pages.

WILLIAM CHESTER.—On Saturday, July 28, Mr. W. Chester, head gardener to the Duke of Devonshire at Chatsworth, passed away suddenly. Deceased, who has lived at Chatsworth for nearly half a century, succeeded to the position of head gardener there on the appointment many years ago of Mr. Owen Thomas to be head gardener at Windsor. The funeral took place on Tuesday last.

JOS. FORSYTH JOHNSON, the landscape gardener, who was well known in London some 20 years ago in connection with the landscape work of the Alexandra Palace, and, previously to that was connected with the Manchester Botanic Gardens, died suddenly in New York, U.S.A., on July 17. Mr. Johnson was suddenly stricken during a period of particularly torrid weather while sitting in the dining-room of the hotel where he had resided for several years. He was taken to a hospital, and died within a few hours. Since leaving England, some 18 to 20 years ago, Mr. Johnson has been engaged in landscape gardening in the neighbourhood of New York chiefly, and nearly always on private estates. We are requested by our New York correspondent to suggest that anyone directly concerned in the affairs of the late Mr. Johnson should communicate with Mr. Patrick O'Mara, 35, Cortlandt Street, New York City, who will be pleased to attend to whatever matters may arise, especially in connection with his family. Mr. Johnson was the author of a work on landscape gardening and was an occasional contributor to this journal.

ROYAL HORTICULTURAL SOCIETY.

International Conference on Hybridisation and Cross-Breeding.

UNDER the auspices of the R.H.S. there has been held during the week an International Conference on Hybridisation and Cross-Breeding, in which many prominent British and Continental horticulturists took part.

On Monday evening there was a conversazione at the Society's Hall, Vincent Square, Westminster, when the delegates from abroad were introduced to their British fellow-scientists. Sir Trevor Lawrence, the President of the R.H.S., welcomed the guests. He said he did so, not only in the name of the Society, but, he was sure, of the whole world who were interested in horticultural pursuits. A few words about the R.H.S. might be interesting to many of the guests. The Society was in the 103rd year of its existence. During that long period it had had many ups and downs. A good many years ago part of its work was to send collectors abroad, with the object of gathering such shrubs, plants, trees, seeds and bulbs as might be considered advisable, but in that respect private enterprise had taken the place of the Society, and it was a matter for congratulation that the Society was now able to devote its energies to guiding and protecting the horticultural interests of this country. The gardening industry of this country was a very important one, and, he might say, was at the head of the minor industries of this country. He was sure they would listen with interest and pay the greatest attention to the papers that would be read to the Conference. They owed a very great deal to the enterprise, intelligence, and sagacity which had been at the root of all the progress that had been made. As illustrating the great strides that had been made he pointed to the display of Begonias at Holland House. He could, he said, point to many other things, but the Begonias were the most immediately striking. The same procedure had been followed in many other classes of plants, fruits, and vegetables, and the general public did not fully realise—as it was desirable that they should—the great obligation they were under to plant-breeders. He had often thought what would have been the position of this country but for the industry and sagacity of the horticulturist. We should be left with a few trees, a few shrubs, and, speaking comparatively, a few plants; but now there was scarcely a garden however humble that did not contain some plants that owed their existence to the intelligence of plant-breeders. He did not think that this country grasped the importance of the subject, and he believed we were very much behind other countries in this respect. Why had that eminent scientist, Dr. Perkin, to take his remarkable discoveries to other countries? He ventured to remind them of Huxley's words that the scientific spirit was more valuable than any of its results. That was the spirit needed in this country, and it was a remarkable thing that the present House of Commons did not contain a single person whose scientific knowledge was worth a ——, and the President snapped his fingers. With regard to plant breeding—and he did not claim to be a scientist—he had devoted a certain amount of attention to the cultivation of Orchids, and he could recommend it as a most instructive pursuit. Before long the supply of Orchids from abroad would cease, and we should be entirely dependent upon our own breeders. There was scarcely a collector who had not got his house full of seedlings. They were all in that position. They were often disappointed; but he only mentioned the subject to show what was being done in that direction. A number of interesting papers had been promised, and it was known that they were of great value, judging by the names attached to them. All the papers would appear fully in the *Journal*. He again extended the welcome of the Council to their guests.

THE CONFERENCE.

The Conference opened on Tuesday morning, when W. Bateson, Esq., F.R.S., V.M.H., President of the Conference, presided over a large gathering.

Sir Trevor Lawrence again spoke a few words of welcome, and said it was quite unnecessary for him to introduce to the meeting so eminent a man of science as their Chairman.

The Chairman of the Conference then rose amid cheers to deliver his opening address, which is printed in full on pp. 81, 82, and 83.

The first paper which was read on conclusion of the President's address was entitled:

"DOES HYBRIDISATION INCREASE FLUCTUATING VARIABILITY?"

Professor Johannsen, of Copenhagen, read a paper on this subject. He said the question of heredity was a very important one, and the results of statistical and other forms of research did not always agree, and it was their business to discover the reason. He regarded statistical data as very misleading, because Mendel's researches could not account for all the problems of heredity, and the question whether evolution was continuous or discontinuous could not be fully elucidated by Mendel's researches. Research showed that discontinuity was a fact in nature.

The Chairman said the problem was one of extreme difficulty. What happened when pure types differentiated by small fluctuations when they were crossed was not known, but there was the suggestion that what took place was the same in animals as in plants.

Professor Plate, of Berlin, said if they took a pure type and kept to self-fertilisation they could not expect variation; but as soon as the outward conditions were changed there would be fluctuation, and Professor Johannsen had not convinced him that continuous variation did not exist.

Mr. G. U. Yule, University College, London, said he had not been entirely won to the professor's views. The data, however, at their disposal was quite inadequate, and they must suspend their judgment.

The Chairman agreed that their judgment must be suspended, and that the answer must come from later generations.

"MENDELIAN CHARACTERS IN PLANTS AND ANIMALS."

Mr. C. C. Hurst, of Hinckley, dealt with this subject. In view of the discussion which had taken place, he said that for the last two years he had been carrying out experiments of the same nature as those of Professor Johannsen. He chose the Dutch rabbit for his subject, but the results had been purely negative. He described experiments he had made with Sweet Peas, and pointed to all the different grades of colour. He thought it would be found that the supposed continuous variations were really discontinuous, and that the continuous variation was merely somatic and altogether apart from heredity. He described one of the Sweet Peas as white, whereupon Miss Wheldale, of Newnham College, Cambridge, asked if what Mr. Hurst described as white was a true albino.

Sir Michael Foster said it was extremely desirable that spectrum nomenclature should be adopted. That would do away with the confusion of calling cream white.

The Chairman asked whether there existed a spectrum nomenclature which ordinary people could comprehend?

Sir Michael Foster said there would be no difficulty about that, and he supposed everyone had seen the rainbow.

Professor Wittmack said much could be done by microscopical investigation. Sir Michael Foster agreed, and Professor Plate mentioned that there already existed a German work giving 700 colours.

[*The Repertoire de Couleurs*, published under the auspices of the French Chrysanthemum Society, a copy of which was procured from the Lindley Library, was here produced. Many other speakers took part in the discussion.]

"ANIMAL BREEDING."

Mr. A. Darbishire, Royal College of Science, London, contributed a paper on "Recent Advances on Animal Breeding, and their Bearing on our Knowledge of Heredity." He illustrated his remarks by basing them on the sexual history of snails.

Dr. Lotsy spoke in confirmation.

MENDEL'S LAWS.

Mr. G. Uday Yule, of University College, London, followed with a paper dealing with "The Theory of Inheritance of Quantitative Compound Characters on the Basis of Mendel's Laws."

The paper was so exceedingly technical, and as no one responded to the Chairman's invitation to discuss the subject, the Chairman observed amid laughter that they seemed to have reached the limit of their capacity to grasp anything further.

In the afternoon meeting on Tuesday the first paper read was one on certain "Complications in Cross-Breeding of Stocks," by Miss Saunders, of Newnham College, Cambridge. She dealt at great length, but very lucidly, on the results of crossing hoary with glabrous stocks; but so technical was her paper that she illustrated it with the following diagram, showing that hoariness could not be manifested in the absence of sap-colour.

Any glabrous sap-colour × any glabrous sap-colour.

|

F1 = all sap-coloured glabrous.

F2 = all sap-coloured glabrous.

Any glabrous sap-colour × any glabrous non sap-colour (white or cream)

|

F1 $\frac{1}{1}$ all sap-coloured hoary.

F2 = 9 sap-coloured hoary: 3 sap-coloured glabrous: 4 non sap-coloured glabrous.

White glabrous × cream glabrous.

F1 = all sap-coloured hoary.

|

F2 = 9 sap-coloured hoary: 7 non sap-coloured glabrous.

Miss Sanders added that there seemed to be a curious connection between flower colouring and the occurrence of doubling.

The Chairman said the matter was very complicated. They had the single variety throwing off the double parent, and yet the double form did not set seeds. There was also the remarkable paradox that a great number of single varieties gave 80 per cent. of double Stocks. That was due to some physiological cause entirely unknown, and he hoped Miss Sanders would succeed in solving the problem.

Mr. Fenn thought it might be the result of planting double Stocks in conjunction with the single Stock, and that gave predominance of the double Stock from the single variety. Whether it was done by the bees he did not know.

Mr. Arthur Sutton said the question of single Stocks giving double flowers was an intensely interesting one. He did not think there was much in Mr. Fenn's theory. There seemed to be something absolutely inherent in the strain. He hoped Miss Sanders would soon elucidate the mystery.

Mr. Dippe, Quedlinburg, said he was still engaged on investigations to discover the effect of sowing Stocks in pots or in the open ground, with reference to the production of double flowers.

Miss Sanders said the suggested explanation that it was caused by planting the double with the single was merely a tradition. The double Stock was absolutely sterile. If they were to get any further results it would have to be through individuals.

Mr. Fenn asked what the bee was doing in the double Stock if there was no pollen? He thought the bee was after the pollen.

Miss Sanders: No, because there is none.

The Chairman: Perhaps the bee goes to try.

Mr. Fenn said he had seen the bee work in the double and directly afterwards in the single, and he should certainly rely upon it as an evidence of cross fertilisation.

M. P. de Vilmorin said there were no practical means of determining which plant will produce double flowers.

Infertile Hybrids.

Dr. John H. Wilson, F.R.S.E., of the University of St. Andrews, Scotland, contributed a paper on "Infertile Hybrids," and accompanied his observations with many beautiful lantern slides. He said the whole history of fertilising hybrids was one of failure. Infertility was the most outstanding feature of hybrids. He would not believe that they had got to the bottom of the subject yet. He had experimented with the following. (A list of Dr. Wilson's exhibits is given in another column.)

Mr. Fenn, who is perhaps the oldest living member of the R.H.S., told how as far back as 1827 he experimented with Potatos, and in 1845 it struck him that if a Pelargonium could be cross-fertilised, why not a Potato? He immediately set to work on the Black Potato, which he received from New York. He was poohpoohed by the R.H.S. of that day, but eventually he succeeded.

The Chairman suggested that they should not get away from the question of the sterility of hybrids.

Prof. Lotsy said they had been hybridising species of Carex in Leyden, and they had never got a single seed. They had tried with thousands of individuals.

Dr. Woordjun, of Groningen, Holland, followed with a paper on the breeding of Canaries.

Hybrid Cattleyas.

Mr. R. A. Rolfe, of Kew, dealt with this subject. The object he had in view he said was to collect together the natural hybrids of the Cattleya group, which had become rather numerous. The cause was not far to seek. Orchids were largely dependent upon insects for the fertilisation of their flowers, and as insects seldom confined their visits to one particular species, the pollen was very likely to be interchanged, and thus hybrids might occur whenever allied species grew together. In this group, as in some others, it was evident that hybridisation was largely a question of opportunity, for hybrids occurred between some of the most structurally distinct species, where they happened to grow intermixed, uniting the genera Cattleya, Lælia, and Brassavola. From a botanical standpoint it was important that these curious intermediate forms should be taken at their true value, for they destroyed the natural limits of species, sections and genera, and in practice it was found that unless their real origin had been recognised from the outset, they had been classed as anomalous forms or varieties, or as distinct species, according to the amount of difference they presented from existing forms. Mr. Rolfe then gave a historical survey of the subject, from which it appeared that the earliest published allusion to the occurrence of a natural hybrid among Cattleya that he had found occurred in 1856; and he went into great detail as to the homes of the various species.

Hybridisation as a Proof of Natural Affinity in Orchids.

Prof. Pfitzer, of the University of Heidelberg, treated this subject in a very technical paper. He said that the natural arrangement of Orchids was not yet quite settled, but he held the opinion that, if it were possible to get a hybrid between two genera of Orchids, they were certainly nearly related.

Odontoglossum Hybrids.

Mr. de Barri Crawshay, of Sevenoaks, gave an interesting account of many experiments he had made, and he showed to the Conference a number of beautifully-coloured plates.

"The Influence of the Parents on the Colour of the Hybrid."

Mr. F. J. Chittenden read a paper on this subject, of which the following is a summary:—

The statement that the colour of the flowers of a hybrid are more influenced by the pollen parent than by the seed parent has very frequently been made, and the belief that this is true is still widely held. Upon this belief is founded the advice often given to choose the flower with the more brilliant colouring as the pollen parent.

Others who have worked at hybridisation have denied that this belief is true, and have brought forward many examples showing the exact converse.

A knowledge of the laws of inheritance is obviously of importance if the work of hybridising is to be anything more than haphazard, and these laws can only be formulated after careful examination of numbers of hybrids. For this reason, and because, in the first place, in the first generation reciprocal crosses usually produce offspring that are as little different from one another as are the offspring of a pure species, and, in the second place, the recent investigations into the truth of Mendel's laws of inheritance have shown that the first law, which states that of certain characters one of a pair only is dominant and apparent in the first generation, is of wide application, the present investigation was undertaken.

The records of 183 hybrids (mostly first crosses), of which the parentage appeared to admit of no doubt, belonging to 67 genera, were carefully examined, and a comparison of the colours of the hybrids with those of their parents made. Of these 183, 19 had parents whose flowers were alike in colour, and of the remaining 164 42 showed a predominance of the coloration of the male in their flowers, 46 showed a predominance of the female, three had characters not possessed either by the male or the female, and the remaining 73 were intermediate in their coloration.

It is therefore concluded that no general rule of dominance of male over female or vice versa, so far as the coloration of the hybrid is concerned, can be formulated; but we must look to the discovery of the dominating characters (which are the ones to appear in the first generation of the hybrids), whether possessed by the male or the female, before any general rule upon the subject can be formulated.

Several other papers were taken as read.

DINNER TO DELEGATES.

A dinner to the Foreign and British delegates took place at the Hotel Windsor, on Tuesday evening. The delegates were the guests of the Horticultural Club. Sir J. T. D. Llewelyn, Bart., President of the Club, presided, and he was supported by Mr. Harry J. Veitch (Vice-Chairman), Mr. E. T. Cook (Hon. Sec.), Mr. Bateson (President of the Hybrid Conference), Sir Trevor Lawrence, Bart., &c.

After the loyal toasts had been duly honoured, Sir Daniel Morris, K.C.M.G., proposed "The Royal Horticultural Society," congratulating the President, Secretary, and all concerned on the great success which had attended their untiring efforts to bring the Society up to its present standard. He alluded to what Baron Schroeder had done for the Society.

Sir Trevor Lawrence responded. He said the Society had been through dark and troublous times, and he gladly seconded all that had been said about Baron Schroeder. Their finances were now on a sound basis; they had a magnificent hall, which cost upwards of £40,000, all absolutely paid for; and they had a garden which was given them by Sir Thomas Hanbury, to whom they were greatly indebted, because it was exactly the sort of garden they needed. Indeed, they were so flourishing, and the membership had grown so, that he feared they would soon have to close the list of members. (A laugh.)

The Chairman then proposed "Our Guests." He said horticulture was useful, elevating, pure, healthy, and progressive, and it was with great heartiness they welcomed around them those who were doing so much to further its interests.

Mr. Bateson was the first to respond. He said he wished he could express some part of what he felt in rising to return thanks for the guests. That was a very different occasion from the one in 1898 when he had the honour of being the guest of the Horticultural Club. Then the company numbered about thirty, and included the members of the Hybridisation Committee. One had only to look round to see how wonderful had been the development since those days, how the interest had increased, as well as the quality of the subjects discussed. That entertainment had been princely. He regretted deeply that Professor De Vries was not with them that night—that professor who in 1898 startled the scientific world by his discoveries. Like many British works of art, he had been absorbed—for the time being—by American enterprise, but, happily, unlike works of art, he would come back. (Cheers.) Then Professor Correns was absent—a gentleman whose name would live as long as science itself. They were very sorry ill-health kept him away; but there were many present that evening who would make that gathering distinguished. When he asked himself the meaning of all that princely hospitality he really could give no answer. He wondered sometimes whether they really had a valid position; but he felt, after all, that science and practice in horticulture should go hand in hand, and they were there that night to declare their belief that the promises made on behalf of that union would yet be fulfilled. He never could believe that all their efforts would be wasted, and there was a solidarity in their union which would last for many a day to come. The great thing was not to promise too much. Science could not do the impossible. They could not get a yellow Pea from a white, or a red from a yellow, if the white and the yellow were non-existent; but if the colours were there, science would get at them. He believed, however, if the scientific were successfully combined with the practical, they would be able to produce something very remarkable. One thing was taught them by science and that was patience. (A voice: "Rather!" and laughter.) He did not refer to that patience necessary to watch a seed grow, but to that patience which was needed when scientists were speaking about matters which were absolutely unintelligible. (Laughter). The present union of science with the practical was most bizarre—each got something from the other. He felt every confidence that that union would last for many years, and would be extraordinarily prolific. The day was past when their subjects would suffer from want of interest. There would be quite sufficient interest to carry them over the dead point, and then their work would become a living reality. If some things could only be understood, he believed that quite a new era for plants and animals would begin. (Loud cheers.)

M. Philippe de Vilmorin, of Paris, M. Johannsen, of Copenhagen, and Prof. Wittmack also responded.

Lieut.-Col. D. Prain proposed "The Chairman," and called for a hearty toast for "a good gardener, a great sportsman, and an all-round English gentleman."

Sir John Llewelyn briefly responded, and thanked Col. Prain, who, their friends would like to know, was a Fellow of the Royal Society, and the distinguished head of the great national garden at Kew—a garden of which they were all exceedingly proud. He also paid what he said was but a well-deserved tribute to their Secretary, Mr. Cook, and to the members of that Club, especially their old friends Mr. Paul, Mr. Veitch, Mr. Bunyard, and Mr. May.

CONFERENCE.—WEDNESDAY.

The Conference resumed on Wednesday morning.

Origin of New Forms.

Dr. E. Tschermak, of Vienna, read a paper on "The Bearing of Hybridisation on the Origin of New Forms." Up to a few years ago, he said, it was the opinion of scientists that hybridisation was of no great consequence for the production of new forms with direct reference to a study of the descent or pedigree. Practical breeders, on the other hand, had long learnt to regard scientific crossings as a means which, in certain cases, influenced the production of apparently new forms. In any case, no sort of general laws seemed to exist. So as to secure even the commercial benefits of lucky accidents, the cloak of secrecy was thrown by many breeders over the origin of their new products. Consequently, even now many forms were wrongly described as hybrids or bastards; and, on the other hand, many novelties, the origin of which was not given, led back with certainty or probability to an intentional or an unintentional cross. Already hybridisation possessed a much greater importance for the formation of new groups from the possibility of a production of new Mendelian combinations of characteristics and component characteristics. The most striking feature in the evolution significant of hybridisation showed itself in the occasional unexpected evolution of wholly new forms through crossing.

Hybrid Rose.

M. Maurice de Vilmorin communicated a note on a new hybrid Rose, a painting of which he passed round for the examination of the Conference, between Rosa rugosa and R. foliolosa, which had the advantage of flowering late in the season.

Mr. Paul congratulated Mr. de Vilmorin on his acquisition.

The Chairman said he should like to ask whether the long flowering was in any way connected with not setting seed?

M. Vilmorin said it was not—it produced good seed.

Professor Rosenberg, of Stockholm, read a most important paper on "Cytological Investigations on Plant Hybrids," and Herr C. H. Ostenfeld, of Copenhagen, followed with one dealing with "Castration and Hybridisation in the Genus Hieracium."

VISIT TO BURFORD.

The Conference then adjourned till the next day to enable the delegates to visit the delightful country seat of Sir Trevor Lawrence, at Burford.

At the luncheon the pleasant duty of proposing the health of Sir Trevor and Lady Lawrence fell to Professor Wittmack, who was full of praise for all that had been done for the entertainment of the guests.

We shall refer in our next issue to the proceedings on Thursday and Friday.

Exhibits Bearing on Hybridity, Law of Heredity, &c.

There were numerous exhibits having to do with the subject of the Conference in one form or another but chiefly on the questions of heredity, and the "dominant" and "recessive" characters in various plants. In most cases there were insufficient particulars given of these crosses for the average visitor to be much interested by them, even assuming that he possessed some knowledge of the subject. The exhibitor knew just why the particular crosses were made, and the value of a knowledge of the results which followed, therefore the final results especially should have been set out together with the bearing it was assumed they might have on the general question. Otherwise the mere enumeration of crosses with the separate results is of little value at an exhibition. They require to be published that the details may be studied by all interested in the subject, but this defect will be remedied when the volume in which the proceedings are to be published is issued

Mr. C. T. Druery exhibited Scolopendrium hybridum, which is presumed to be a natural hybrid between S. hemionitis (?) or S. vulgare, and Ceterach officinarum. Only one plant was found on an old wall in a vineyard near Portozigale in the Island of Lossin (see *Briton's European Ferns*, p. 137). Although presumably a hybrid since it partakes of the characters of both attributed parents, its spores are perfectly fertile and reproduce the type exactly. The plant shown was raised from spores by Dr. Rosenstock.

From Miss Saunders, Cambridge, were contributed many interesting exhibits. Some of these were as follow: Mercurialis annua, to show that plants produced parthenogenetically are all female; seedling Stocks showing that the produce of a hoary crossbred, produced by crossing two glabrous types, were of mixed character—some hoary and others glabrous, also the flowers were very varied—some white, others coloured, some selfs, others bicolors. But those which were hoary and those glabrous appeared to be unaffected by each other, these characteristics apparently remaining unmixed in the individual plants. Some growing plants of Salvia Horminum were shown for the purpose of illustrating that S. rosea (*b*) was recessive to S. violacea (type) (*b*), and S. alba (*c*) recessive to S. rosea (*b*) In the first generation, from seeds obtained from a cross between *b* and *c*, where the white parent contained B two plants were shown which were purple. In the second generation, from seeds obtained from crossing white with pink, where the white parent did not contain B there were three pink-flowered plants to one white-flowered plant In the second generation, from seeds obtained by crossing white with pink, where the white parent contained B there were nine purples, three red, and four whites

Some seedling Primulas were shown by Mr. W. Bateson and Mr. R. P. Gregory, showing that in one dozen plants there were nine palm leaved (dominant) and three fern-leaved (recessive). This proportion appeared in the F 2 (second generation) from a cross effected between the types It may be remarked that the fern-leaved type (recessive) breeds true.

On the subject of inheritance of sex some plants of Bryonia alba and B. dioica were shown to illustrate and confirm the experiments of Correns. Bryonia alba is monoecious and B. dioica is dioecious. Between these species reciprocal crosses give dissimilar results. B. alba ♀ × B dioica ♂ gives ♂'s and ♀'s in equal numbers, but B. dioica ♀ × B. alba ♂ gives only plants which are ♀ except for rare ♂ flowers at bases of stems. All these hybrids so far have been totally sterile.

The rules of heredity were further illustrated by Mr. W. Bateson and R. C. Punnett. There were numerous specimens to illustrate the findings, some of which appeared to be as follow: White Sweet Peas when "selfed" breed true. When, however, a cross is made between certain strains of whites, all the offspring are purple; such purples on "selfing" give purples, reds, and whites in the proportions of 27: 9: 28. White × with another white produced purple, and the purple self-fertilised produced 29 purples, nine red, and 28 whites. On raising a subsequent generation from the F2 plants, the 27 purples are found to consist of four different kinds, namely:—

(*a*). Those giving purples, reds, and whites, 16 in number.
(*b*). Those giving purples and whites, eight in number.
(*c*). Those giving purples and red, two in number.
(*d*). Those giving purples only, one in number.

Similarly among the nine reds there were:—

(*a*). Eight giving red and whites.
(*b*). One giving reds only

(These reds never give a purple, and the whites always breed true)

The chance of a purple coming in the F2 (second) generation is, therefore, 1 in 27, and of a pure red is 1 in 9. Moreover, the composition of each plant is shown by its offspring Consequently, by saving from individuals which are thus proved to be pure, these types may at once be fixed.

A curious case of reversion was illustrated in a cross between White Cupid (round pollen), a dwarf plant of procumbent habit, and White Bush (long pollen), a variety growing 3 feet high. The seedling was very much taller than the taller parent and it had purple colour, being, therefore, both a reversion in height and colour.

An autograph letter from Mendel to Naegeli, referring to experiments with Hieracium, was sent by Professor C. Correns, of Leipzig, and was published in Gregor *Mendel's Briefe*, p. 219

A very large number of crosses with Peas were shown by Mr. R. H. Lock, in which a considerable number of characteristics was illustrated and the dominant and recessive characters proved. Some specimens of Maize grown by the same exhibitor in the Royal Botanic Gardens, Peradeniya, Ceylon, 1902-1904, were also exceedingly interesting, because visitors could easily see the results of heredity in such cases where all the variations are exemplified in each single aggregation of fruits. One curiously proportionate result was a case in which yellow smooth was crossed with white wrinkled, the seedlings containing 25 per cent yellow smooth, 25 per cent. yellow wrinkled, 25 per cent. white smooth, and 25 per cent. white wrinkled.

Messrs. Laxton Brothers, Bedford, exhibited fruits of the Loganberry, and of a cross between the Loganberry and the Raspberry, and other interesting things.

From Mr. G. Yeld, York, come flowers of Hemerocallis Thunbergi (seed parent) and H. aurantiaca (pollen parent), and of a number of seedlings from this cross, &c.

Some coloured drawings of Pine Apple fruits showed by W. Fawcett, Esq., of the Imperial Agricultural Department of the West Indies, represented crosses which had been made with varieties of these

A whole series of crosses between varieties of Antirrhinum involving much detail was shown by Miss Wheldane and Miss Marryat, all giving results bearing on the subject of heredity.

Dr. John H. Wilson exhibited mounted wheats to illustrate what happens when a bearded was crossed with a beardless variety. The segregation showed the now well-known fact that the bearded condition was recessive. The effect of crossing Sugar Pea with Gradus was shown in pods of the first generation, the inner membrane, characteristic of the pod of the ordinary Pea, being seen to be dominant. Amongst crossed Rubi were shown crosses between Japanese Wineberry and Raspberry, Blackcap and Strawberry-Raspberry, Loganberry and Raspberry. A cross between Gooseberry and flowering Currant was also shown. It had never flowered. Dr. Wilson gave, at one of the meetings of the conference, a lantern demonstration of hybrids which he had found to illustrate infertility. He described crosses in Foxgloves, and he found that when the white Foxglove was crossed with Digitalis lutea the resulting hybrid was distinct from that having the purple Foxglove as parent. The reciprocal crosses, too, were also different in many respects. All these Foxglove hybrids were infertile. Amongst Begonias, Dr. Wilson described a number which had refused to flower, others which flowered and bore good seed. In the cross between B. foliosa and B. fuchsioides he found that the hybrid produced progeny like itself, and no evidence of Mendelian segregation. The cross between Rubus occidentalis and R. rosæfolius was quite sterile. The Loganberry was, as was well known, a spontaneous hybrid, bearing good seed.

Mr. R. J. Lynch, curator of the Botanic Gardens, Cambridge, made an exhibit which contained the following plants:—Kalanchoe kewensis, K. flammea, K. Benti; Sarracenia Drummondi × variolaris, good plant, S. Drummondi, S. variolaris; Nepenthes Allardi, raised by E. J. Allard (N. Veitchi × N. Curtisi), N. Veitchi (cut pitchers only), N. Curtisii (cut pitchers only); Begonia × Weltoniensis (Col. T. Clarke's hybrid), B. Sutherlandi, B. Dregei; Senecio squalidus × vulgaris, a weed in the Cambridge Botanic Garden, S. vulgaris and S. squalidus; Aloe Lynchi, A. albocincta, Gasteria verrucosa; Aloe cantabrigiensis, A. somaliensis, A. Schimperi; Cineraria, single plant, containing common garden Cineraria and all the allied species that have been cultivated in the Cambridge Botanic Garden; Kalanchoe grandiflora × Kirki, K. cantabrigiensis, K. grandiflora, K. Kirki; Begonia Pearcei, the parent from which came the yellow colour in tuberous Begonias; Cytisus Adami, branch, C. Laburnum, raised from the Laburnum part and certainly pure Laburnum (raised 1898), C. purpureus (not yet flowered), raised from a corresponding part of Adami; Polypodium Schneideri, P. aureum, P. vulgare var. elegantissimum; Scolopendrium vulgare × Aspl. Ceterach, Clematis coccinea and hybrids, with "Star of India."

Experiments on heredity in pigeons was illustrated by stuffed birds and considerable data from R. Staples Browne, Esq.

From Mr. L. Doncaster came rats' skins and data referring to heredity in respect to colour, and he states assuming that every albino rat is a grey or a black rat with the pigment undeveloped, the general results obtained from the crossings are in agreement with the Mendelian principles. Mr. Doncaster exhibited some very beautiful specimens of the Lepidoptera bearing on the same question.

Ducks were shown by Mr. J. L. Bouhote, and illustrations of colour crossings in mice by Miss F. M. Durham

Dominant and recessive characteristics in fowls' combs were brought out in a series of crosses made by Prof. W. Bateson and Mr. R. C. Punnett, also of colour in Andalusian fowls and in game bantams.

Mr. C. C. Hurst, who contributed the article on the Mendelian Theory published in our pages on March 24 last, p. 187, exhibited skins of rabbits, also of crosses in Sweet Peas and Antirrhinums. The results in the Sweet Peas were somewhat similar to those obtained by Prof. Bateson, but the varieties experimented with were not the same as those he used.

The inheritance of horns in sheep and of face colour was illustrated by data and pictures contributed by Mr. T. B. Wood.

A. D. Darbishire, Esq., exhibited Japanese waltzing mice, and crosses between these and others of the ordinary type.

The Committees.

July 31.—The meeting of the Committees on Tuesday last in the Hall in Vincent Square being simultaneous with the opening of the Hybridisation Conference, this latter event claimed a large share of the day's interest. Many of the exhibits were really conference exhibits, and even in the ordinary contributions from accustomed exhibitors something or other having some bearing on the subjects of genetic variation and heredity was generally included. The display of Orchids was excellent for this late season, and eight novelties obtained the Orchid Committee's approval, four of which were awarded First-Class Certificates, and four Awards of Merit.

The FLORAL COMMITTEE recommended five Awards of Merit to plants which are described below.

The exhibits before the FRUIT AND VEGETABLE COMMITTEE were of small extent.

The attendance during any part of the day was only moderate, but with the hot sunshine directly upon the glass roof the atmosphere of the building was very warm, notwithstanding the lack of visitors, other than members of the conference.

Floral Committee.

Present: H. B. May, Esq. (in the chair), and Messrs. R. Wilson Ker, G. Reuthe, Geo. Nicholson, W. G. Baker, Jno. Green, J. F. McLeod, W. Howe, C. R. Fielder, J. W. Barr, R. W. Wallace, Chas. Dixon, H. J. Cutbush, C. E. Pearson, W. P. Thomson, E. H. Jenkins, R. C. Notcutt, Amos Perry, J. Hudson, and R. Hooper Pearson.

Coleus Pride of Chesham was exhibited by Mrs. W. MATTHEWS, Chesham Park, Anerley (gr. Mr. C. Thrower). The leaves were very narrow, restricted, much serrated, and at a short distance had something of the appearance of a Codiæum. The colours were red and bronze.

Messrs. KELWAY & SON, Langport Nurseries, Somerset, contributed a fine display of Gladioli, in the numerous choice varieties raised by this firm, and showing, as usual, very superior cultivation. Picard, a large flower of salmon-pink colour, with yellow blotches spotted with the general colour of the flower was conspicuous, and of the nnmerous other sorts we can only mention here Mrs. J. W. Skittery, yellow; Agalla, rich rosy-crimson with yellow blotches; Triptolemus, cherry-red; Duchess of Leeds, white with pink blotches; and Lady M. Digby, sulphur coloured with a little richer yellow around the blotches of reddish crimson. (Silver Banksian Medal.)

Mr. L. R. RUSSELL, Richmond Nurseries, Surrey, exhibited a very fine group of Ivies of the Hedera arborea type, standard and dwarf plants arranged in a corner of the hall where they had a very pretty effect. The golden varieties were richly coloured, and included H. helix flavescens, H. arborea spectabilis aurea, Russell's Golden, &c. The silver and green-leaved H. arborea elegantissima was very bright.

Messrs. H. B. MAY & SONS, Edmonton, put up a very fine group of Ferns, chiefly varieties of their own raising. Nephrolepis were represented by some remarkably distinct forms. N. angustata cristata, N. rufescens Mayi, N exaltata superba, N. exaltata rugosa, N. rufescens falcata, N pectinata concinna and N. cordifolia elegans were all interesting and pretty forms; N. cordifolia crispata congesta, a curious little fern. Osmunda palustris Mayi, Pteris cretica generosa, P cretica grandiceps, P. c. Summersi, P leptophylla princeps, Asplenium Herbstii, A. Mayi, &c. (Silver Gilt Floral Medal.)

Messrs. H. CANNELL & SONS, Swanley, put up a good exhibit of double-flowered tuberous rooted Begonias and some interesting hybrid Fuchsias, also the old variety Venus Victrix from which so many varieties have been raised.

Messrs. SUTTON & SONS, Reading, filled a table with magnificent Gloxinias. The pure white flowers were very fine, and there were also spotted varieties and flowers of various shades of colour, the plants were barely five months old from the time of sowing the seeds, but they were very freely flowered. (Silver Floral Medal.)

Messrs. R. & G. CUTHBERT, Southgate, arranged a large group of flowering plants, including Lilium auratum, L. longiflorum and L. speciosum (lancifolium), good Rambler Roses, Verbenas, Palms, Ferns, &c, interspersed with each other to afford a good effect.

Mr. G. REUTHE, Keston, showed some choice hardy flowers, among them Campanula grandiflora macrantha, Desfontainia spinosa, Lilium canadense, L. superbum, Cytisus nigricans, Veratrum nigrum and other pretty things.

Messrs. J. LAING & SONS, Forest Hill, showed a group of Codiæums, in well coloured plants of a useful size for table decoration.

Mr. R. C. NOTCUTT, Woodbridge, Suffolk, showed a good collection of hardy flowers, including Statices in white, yellow, and blue shades.

Mr. R. HOFFMANN, Tower House, Streatham (gr. Mr. T. Tomlinson), sent a good group of Caladiums, for which a Bronze Medal was awarded.

Varieties of Chrysanthemum maximum were shown by Mr. J. G. HAWLEY, Rotherham, and Mr. A. ANDREWS, Campsea Ashe, Wickham Market.

Messrs. W. PAUL & SON, Waltham Cross Nurseries, Herts, exhibited an interesting collection of Roses, chiefly varieties of their own raising, and showing flowers of the parents with them, for instance with Earl of Warwick, The Queen and Mrs. W. J. Grant, the two parents. The hybrid China × Teas were pretty.

Messrs. CARTER & CO., Holborn, exhibited Ten Week Stocks (double) in a variety of colours.

Messrs W. BULL & SONS, Chelsea, put up a group of Hydrangea Hortensia nivalis, a very pretty variegated variety, the white markings being linear and very distinct.

Messrs. R. WALLACE & Co., Colchester, exhibited some choice hardy flowers, including very fine varieties of Montbretias, including the variety Prometheus, also Liliums and Stokesia cyanea præcox, a great improvement on the old form.

Mr. AMOS PERRY, Winchmore Hill Nurseries, had a large group of hardy flowers, including Nymphæas in variety, Campanula grandiflora, Stokesia cyanea præcox, Asclepias tuberosa, Calla Mrs. Roosevelt and Allium sphærocephalum. (Silver Banksian Medal.)

Mr. M. PRICHARD, Christchurch, Hants, also exhibited a large collection of hardy flowers, Kniphofias, Delphiniums, Gladioli, &c., being among the principal species.

Mr CHARLES BREADMORE, Winchester, exhibited a fine collection of Sweet Peas, one of which gained an Award of Merit (see below). (Silver-Gilt Banksian Medal.)

Messrs. CHEAL & SONS, Crawley, put up a nice group of hardy flowers, and in addition Cactus Dahlias were shown in about two dozen varieties.

PERENNIAL PHLOX.

Messrs. T. S. WARE, Feltham, had a showy group of flowers, herbaceous Phlox being the chief feature. Lathyrus latifolius grandiflorus albus, &c, were also well shown.

Mr. PERCY WATERER, Fawkham, Kent, arranged a large, circular group of herbaceous Phloxes in the centre of the hall, it was a well-disposed group, and consisted of the finest varieties. Aurore, Flambeau, Crepuscule, Josephine Gerbause, Mrs. Barr, Fiancée, Delicate, La Cygne, and others were good. (Silver-Gilt Floral Medal.)

Messrs GUNN & SONS, Olton, Birmingham, also made a fine exhibit of the same type of Phlox. Sylphide, Mrs Pemberton, Toreador, Flambeau, Sheriff, Ivory, and Iris were among the most distinct varieties.

The KING'S ACRE NURSERY COMPANY, Hereford, filled a 50 feet long table with Roses put up in large bunches. Some good flowers of various sections were shown, but they suffered much from the excessive heat

CARNATIONS

were shown by several of the trade cultivators of this popular flower. Messrs. WM. ARTINDALE and SON, Nether Green Nurseries, Sheffield, had a display comprised chiefly of border varieties, arranged in bunches with natural foliage, in the ordinary green jars. The flowers were of very good quality, and some of the yellow-ground varieties particularly pretty (Silver Flora Medal). Mr. A. F. DUTTON, Iver Nursery, Bucks, had a display of the tree varieties, mostly those of American raising. The immense shower bouquets of Enchantress and Mrs. T. W. Lawson, slightly depending from tall trumpet-shaped glasses, had an exceedingly good effect (Silver Gilt Banksian Medal). Another collection of similar varieties from Messrs. W. CUTBUSH & SON, Highgate Nurseries, Herts, was associated with border varieties and some excellent flowers of Sault and other Souvenir de la Malmaison varieties (Silver Banksian Medal). Another collection of Carnations at this meeting was one of choice border flowers from Mr. JAMES DOUGLAS, Edenside Nurseries, Great Bookham. These flowers were fresh looking and of very good quality, besides which they represented some of the very best self-coloured sorts, fancies, yellow grounds and other types (Silver Flora Medal). There was still another collection of Carnations, and it was shown by Mr F. M. BRADLEY, Nurseryman, Peterborough. This was the only exhibit on Tuesday in which cut flowers were provided with paper collars. The colours in these flowers were very charming, but they were not enhanced by the collars, especially the pure white flowers. At the back of these were numerous other border varieties, from the same firm, exhibited more naturally in tubes and in Bamboo stands with natural foliage and Gypsophila inflorescence among them.

AWARDS OF MERIT.

Caladium Dorothy Peto, a small-leaved variety with excellent habit as shown. The leaves are very pale rose coloured in the centre, with pea-green margins, the green also extending a little towards the centre in the form of irregular blotches. Shown by Mr. R. Hoffmann.

Nephrolepis pectinata caniculata.—An erect habited plant, with twisted and channelled pinnules, which had also a sort of feather-like growth upon them. Shown by Messrs. H. B. MAY & SONS

Nymphæa atro-purpurea.—This is the richest coloured variety of Marliac's type, having curled anthers, the orange-yellow colour of which is very effective. It is a magnificent flower of large size as well as rich colouring. Shown by Lord HILLINGDON (gr. Mr. A. R Allan).

Stokesia cyanea præcox.—This is a very valuable variety by reason of its early blooming habit, the type rarely flowering before September. S. cyanea præcox grows only about 1½ feet high. Shown by Mr. AMOS PERRY and Messrs. WALLACE & Co.

Sweet Pea Audrey Cuer.—A soft, yet rich-pink coloured variety which has already been described in these columns, shown by Mr. CHAS. BREADMORE, Winchester.

Orchid Committee.

Present: J. Gurney Fowler, Esq., in the Chair, and Messrs. Jas. O'Brien (Hon. Sec.), De B. Crawshay, R. Brooman-White, H. Little, W. Boxall, A. A. McBean, Arthur Dye, W. H. Young, H. G. Alexander, H. Balfantine, F. J. Thorne, W. Bolton, J. Charlesworth, F. Sander, R. G. Thwaites, H. A. Tracy, and Harry J. Veitch.

Messrs. SANDER & SONS, St. Albans, were awarded a Silver Flora Medal for a fine group, in which were examples of the handsome Cattleya Warscewiczii Sanderiana, out of which has flowered the handsome C. W. saturata, which secured a First-Class Certificate (see Awards). Other fine hybrids were Cattleya triumphans, a pretty hybrid of C. Rex; C. Prince Edward (Warscewiczii × Schilleriana), a very showy hybrid; Cypripedium Black Prince (Enryades × Rothschildianum), with nearly black lines on the dorsal sepal; the new O. Fletcherianum, which secured an Award of Merit; O. formosum, a large, pure white flower, with light violet blotches; a fine hybrid between O. Rolfeæ and a spotted O. crispum; O. Ioochristyense, and other good hybrids. In the centre of the group was a batch of Odontoglossum Uro Skinneri; and among others noted were Stanhopea saccata; a nearly white Masdevallia Harryana; Miltonia vexillaria J. Gurney Fowler, with very large, white flowers, tinged with pale lilac, &c.

Messrs. CHARLESWORTH & Co., Heaton, Bradford, secured a Silver Flora Medal for a fine group, rich in good hybrids, the best of which was the beautiful Cattleya Claudian (see Awards). In the group were plants of the fine strain of Odontoglossum Rolfeæ, raised at Heaton, and the richly-coloured O. Harryanum augustum and O. Pescatorei, which are the parents; O. Ossulstoni, O. amabile, and other hybrids; Lælio-Cattleya callistoglossa splendens, with a very large and richly-coloured labellum; Cattleya Fabia, C. Lord Rothschild, a fine specimen of the pure white C. Mossiæ Wageneri, several good forms of Phalænopsis Rimestadtiana, the one named aurea having a yellow base to the lip; the rare P. fasciata, yellow, barred with red; P. intermedia Portei and its parents, P. rosea and P. Aphrodite; Cattleya Leopoldi, C. granulosa Dubuyssoniana, Cymbidium Huttoni, Oncidium stramineum, &c.

Major G. L. HOLFORD, C.I.E., C.V.O., Westonbirt, Tetbury (gr. Mr. H. G. Alexander), staged an interesting group, for which a Silver Banksian Medal was awarded. All the plants shown were raised at Westonbirt. Three are mentioned under "Awards," others composing the group including several remarkably fine Lælio-Cattleya callistoglossa, a nice, light-petalled variety of L.-C. Clive, two L.-C. Baroness Schroder, Cattleya mollis, and two singular hybrids, the one a Cypripedium between C. insigne Sanderæ and C. Maudiæ, but the progeny gives unexpected results, being yellowish in colour with brown markings, and resembling a light-coloured C. Ashburtoniæ; and the other a Lælia between Jongheana and tene

brosa, with very narrow segments of a dull rose colour.

R. I. MEASURES, Esq., Cambridge Lodge, Camberwell (gr. Mr. Smith), was awarded a Silver Banksian Medal for a small group of Anaectochili, in which were several very finely-grown Dossinia marmorata (A. Lowii) and Macodes Petola. Mr. MEASURES also showed Lælio-Cattleya Ingrami Ladymeade variety.

Messrs. STANLEY & Co., Southgate, staged an effective group of Dendrobium Phalænopsis, nine plants of Cypripedium A. de Lairesse, Cattleya Harrisoniana, &c. (Silver Banksian Medal.)

Messrs. HUGH LOW & Co., Enfield, staged an effective group, in which were several good Cattleya Mossiæ, one compact plant having 17 flowers, C. granulosa, C. Leopoldi, a brightly-coloured C. Gaskelliana, C. Loddigesii excellens (a finely-coloured variety), Dendrobium Leeanum Enfieldense (of a light rose colour), Odontoglossum Wallisii, Epidendrum Parkinsonianum, E. campylostalix, E. virens, Broughtonia sanguinea, Bulbophyllum Lobbii, Cypripedium hirsutissimum, C. Frau Ida Brandt, C. gigas Corndean variety, &c. (Silver Banksian Medal.)

FRANCIS WELLESLEY, Esq., Westfield, Woking (gr. Mr. Hopkins), showed Lælio-Cattleya Ihryne albens (L. xanthina × C. Warscewiczii albens), with white sepals and petals, the lip being rose-coloured in front and with an orange disc; L.-C. Miss Gilberta Blount (L.-C. Epicasta × C. aurea), a pretty hybrid, with rosy-lilac sepals and petals, the openly-displayed labellum having an orange-coloured disc, the front and edges of the side lobes being of an intense reddish-maroon colour, darkest around the disc; and Cattleya Eldorado Orange Queen, a very large and fragrant flower, with the sepals and petals light rose-pink, the base and centre of the lip dark orange-coloured. It is nearest to the plant named by the late Professor Reichenbach Cattleya crocea.

Sir FREDERICK WIGAN, Bart., Clare Lawn, East Sheen (gr. Mr. W. H. Young), sent Lælio-Cattleya Ira (L. longipes × L.-C. Schilleriana), a singular cross, with narrow, nearly equal segments, the sepals and petals white, tinged with rose, the lip yellowish, with purple front; also Zygopetalum (Promenæa) stapelioides, which was one of the parents of Z. Crawshayanum.

DE B. CRAWSHAY, Esq., Rosefield, Sevenoaks (gr. Mr. Stables), showed his Zygopetalum Crawshayanum, which had received an Award of Merit, and the finer Z. C. Theodora, a large, bright yellow flower, with dark, reddish bars on the inner parts of the segments; also Z. citrinum, one of the parents.

J. GURNEY FOWLER, Esq., Glebelands, South Woodford (gr. Mr. J. Davis), showed the handsome Cypripedium I'Ansoni, which had previously secured a First-Class Certificate, the bright, purplish-crimson Lælio-Cattleya elegans Proomeana, and the fine L.-C. Atalanta Fowler's variety (see Awards).

Messrs. EDGAR & Co., Montrose, Derby Road, South Woodford, showed a selection of Cypripediums including C. glaucophyllum and C. Kimballianum.

AWARDS.

FIRST-CLASS CERTIFICATE.

Cattleya Lord Rothschild Westonbirt variety (Gaskelliana × Dowiana aurea), from Major G. L. HOLFORD, C.I.E., C.V.O. (gr. Mr. H. G. Alexander).—A superb variety, with large, fragrant flowers. Sepals and petals bright, dark rose, the front of the broad labellum ruby-purple, the base and centre of a rich orange colour.

Odontoglossum crispo-Harryanum Rosslyn variety, from H. T. PITT, Esq., Rosslyn, Stamford Hill (gr. Mr. Thurgood).—One of the finest, largest, and best-grown hybrid Odontoglossums yet shown. The splendid spike bore 14 flowers. Sepals and petals broad, white, with purplish blotches, the tips of the petals being pale rose. Lip very large, white, with violet blotches on the basal half.

Cattleya Warscewiczii aturata, from Messrs. SANDER & SONS, St. Albans.—A great improvement on the remarkable form described many years ago by the late Professor Reichenbach, and the peculiarity of which consists mainly in the almost entire obliteration of the two yellowish patches seen on the lip of typical C. Warscewiczii (gigas). In this case the flower is of the Sanderiana class, large, bright rose, with the extraordinarily-developed lip of a rich, ruby crimson, darkest in the centre.

Cattleya Claudian (Lüddemanniana × Schilleriana), from Messrs. CHARLESWORTH & Co., Heaton, Bradford.—The largest of the hybrids of C. Schilleriana, and a most beautiful flower. Sepals and petals as large as in Cattleya labiata, rosy-lilac, lip formed as in C. Schilleriana, but much larger, beautifully veined with rose-crimson.

AWARD OF MERIT.

Cattleya Atalanta Fowler's variety (Leopoldi × Warscewiczii), from J. GURNEY FOWLER, Esq., Glebelands, South Woodford (gr. Mr. J. Davis).—A very good form and a remarkable colour variation from others of the cross, the flowers having the tints of a good L.-C. elegans. Flowers purplish-rose, with purplish-crimson labellum.

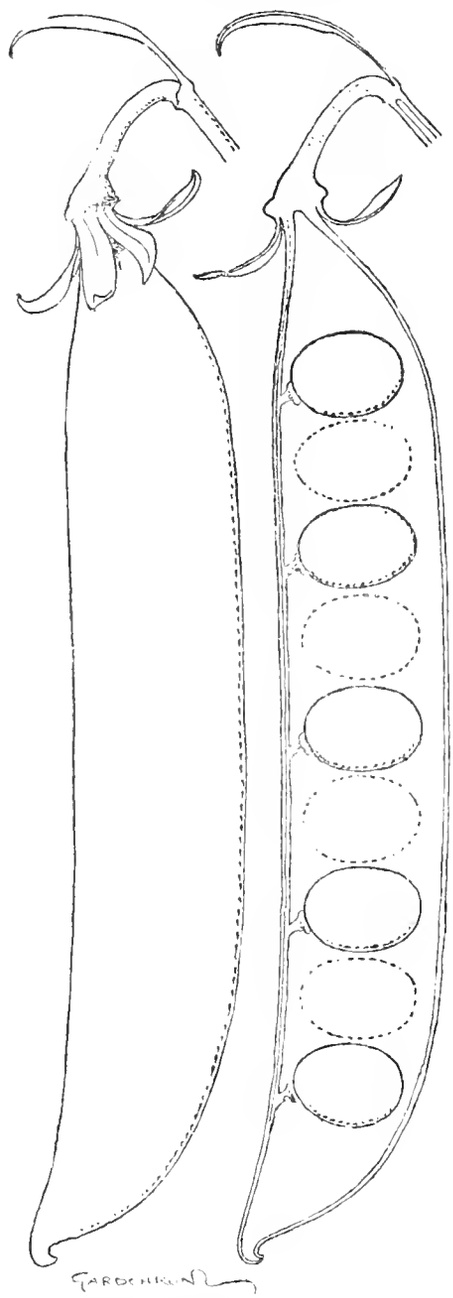

FIG. 38.—NEW CULINARY PEA "QUITE CONTENT," WHICH HAS GENERALLY NINE, AND SOMETIMES ELEVEN, PEAS IN THE POD.

(Shown by Messrs. J. Carter & Co.)

Cattleya Ashtoni Westonbirt variety (Harrisoniana × Warscewiczii), from Major G. L. HOLFORD, C.I.E., C.V.O. (gr. Mr. Alexander).—A very large, rose-coloured variety, the lips having a yellow disc and freckling of purplish rose in front. The fine spike bore four flowers.

Sophro-Lælia Phroso (L. Jongheana × S.-L. læta orpetiana), from Major G. L. HOLFORD.—A pretty addition to these brightly-coloured dwarf hybrid Orchids. Flowers glowing rose-purple, with orange base and crest to the lip.

Odontoglossum Fletcherianum (Edwardi × cirrosum), from Messrs. SANDER & SONS, St. Albans.—A novelty in the group of O. Edwardi crosses of the O. Thompsonianum class, which variety it resembles in all but the cirrosum-like form of the flowers. Sepals and petals dark, reddish-claret coloured, lighter at the apiculate, re-curved tips. Lip one-third shorter than the other segments, formed like O. cirrosum, claret colour at base, rose in front, callus yellow.

Fruit and Vegetable Committee.

Present: Jos. Cheal, Esq., in the chair, and Messrs. H. Parr, W. Bates, Geo. Woodward, S. Mortimer, Alex. Dean, W. Pope, A. R. Allan, J. Davis, Geo. Kelf, F. Q. Lane, G. Reynolds, J. Willard, P. W. Tuckett, C. G. A. Nix, P. C. M. Veitch, Owen Thomas, and W. Poupart.

Messrs. SPOONER & SONS, Hounslow, exhibited a number of fruits of Apple Early Red Margaret. These fruits were of moderate size, of reddish colour throughout, and perfectly ripe, even mealy.

Mr. EDWIN BECKETT, Aldenham House Gardens, Elstree, exhibited pods of the new variety of culinary Pea named "Quite Content" (fig. 38), also excellent roots of Carrot "Blood Red."

Peach "Early Albert," as grown at Holland House, was shown by Lady ILCHESTER (gr. Mr. C. Dixon).

HORTICULTURAL CLUB.

VISIT TO HALTON AND TRING.

Members and friends of the Horticultural Club had their annual outing on Thursday, July 26th, when a visit was made to the gardens of Alfred de Rothschild, Esq., Halton, and those of Lord Rothschild, at Tring Park. The arrangements, undertaken by Mr. Harry J. Veitch, were of the most complete character, and they were carried out to the letter. The weather was glorious, and there were more interesting things to be seen than the party could possibly inspect in the time at disposal. The company numbered nearly seventy ladies and gentlemen, and the journey to the little station of Wendover was commenced at 10.5 a.m., in saloon carriages, from the Great Central terminus in London. Upon arriving at Wendover, a number of brakes conveyed the party to Halton, about five miles distant, and instead of alighting on reaching the residence, the drive was continued—now under the guidance of Mr. Rothschild's steward, Mr. Hubbard, and his gardener, Mr. Sanders—through some picturesque and shady woods, which, if not remarkable for the large size of their timber, were specially agreeable to the visitors for the sylvan character of the varied scene, and for the views of the district obtainable from the top of the hill. Returning to the residence, the party was invited to inspect the rooms on the ground floor of the dwelling-house, which is remarkable for the valuable pictures and expensive French furniture it contains, all of which are of the brightest description possible.

Emerging from the house the visitors found themselves in the front flower garden, and immediately noticed that the bedding was of the gayest description. For a time there was nothing extremely novel, the beds, many of which were raised, being planted with the usual species of flowering plants, but they were exceptionable for their first-class condition.

Presently, however, as an approach was made to some groups and borders of shrubs, which had smaller borders around them as a fringe, so to speak, gay with bedding plants, an unfamiliar effect was observed. Over the face of the shrubs in one border there were circular patches of pink colour, and over those in another border were patches of deep rose or red colour, and the patches were continued up sloping banks to the top of the highest shrubs at the back. The effect was curious. Everyone wondered what the explanation would prove to be. Were they Roses or what? The present writer hurried across the sward and found that the pink colour was that of Ivy-leaved Pelargonium Madame Crousse, and the rose or red colour also of Pelargoniums, but of the newer and deeper-coloured varieties. The plants were in great wire baskets, supported on pedestals at different heights, just so that the plant and its profuse flowers could peep through the face of the shrubs. The feature was unique, and one stepped back again to take another look. This part of the garden did not appear as if in its

everyday aspect, but more as an exhibition for a particular event. Yet this was not the case. By this time Mr. Veitch hurried the party off to the brakes again, which were to take the members to the pavilion in another part of the estate, where Mr. Alfred de Rothschild had provided lunch. This was partaken of, and a telegram of thanks despatched to Mr. Rothschild, votes of thanks given also to Mr. Hubbard, Mr. Sanders, and Mr. Veitch, and the drive to Tring Park commenced without needless delay, the party reflecting on the extraordinary good condition of everything at Halton, indoors and out of doors.

At Tring, a halt was made at the Hon. Walter Rothschild's museum, which contains very much that is interesting in animal, bird, and insect life. Time was insufficient for anything but the most cursory glance at this extraordinary collection of natural history specimens. Leaving the museum, tea was partaken of, which had been provided by the kindness of Lord Rothschild, and a telegram of thanks was despatched to his lordship. After tea, the party divided, and one part made an inspection of the dairy, Jersey cows, &c., and the other part accompanied Mr. Dye, the head gardener, through the gardens, for which purpose, however, the time was all too short. The same order and magnificence was seen here as at Halton, and the style is even more formal. A magnificent specimen of Cedrus atlantica glauca and another of a Weeping Holly excited general admiration. Those who made a tour of the glass-houses and saw the extraordinary specimens of Phalænopsis, and the excellent condition of the extensive collection of Orchids generally, and other plants and fruit trees, were well repaid. Another long drive to Wendover, and the party entrained again for London, reaching the terminus at 8.45 p.m.

SCARBOROUGH FLOWER SHOW.

JULY 26 & 27.—The first flower show held at Scarborough for many years past took place on the above dates. The show was promoted by a local gentleman to benefit the Scarborough Hospital. The whole of the prizes and expenses were subscribed privately, so that the total receipts will be handed to the institution. The show was held in the Belvedere Gardens, by kind permission of the owner, G. Lord Beeforth, Esq., J.P., D.L. These grounds have an extensive frontage to the sea, and as twelve vessels of the Channel Fleet paid a visit to Scarborough at short notice on the show days, an exceedingly fine view was to be had. Those exhibitors who were up early on the Thursday morning staging their exhibits had an opportunity to see the arrival and anchorage of the fleet.

As the Belvedere Gardens are noted for their collection of Roses, an effort had been made to make Carnations the leading feature of the show.

In the class for a group of cut flowers of American or Tree Carnations arranged for effect, Mr. A. F. DUTTON, of Iver, won the 1st prize. In the same tent an exhibition of cut Tree and "Malmaison" Carnations was exhibited, not for competition, by Messrs. W. CUTBUSH & SONS, of Highgate. (Gold Medal.) Silver Medals were also given to Messrs. G. BOYES & CO., Leicester, and Mr. CHAS. A. YOUNG, West Derby, for non-competitive groups of Carnations.

In the class for groups of Carnations in pots, Messrs. WALSHAW & SON won the 1st prize. In the class for Border Carnations, Messrs. WM. ARTINDALE & SON were placed 1st.

The other outstanding features of the show were the Sweet Peas, the hardy flowers, and the bouqets and baskets. The class for twenty-four vases of Sweet Peas in distinct varieties occupied almost the whole of a 70 feet tent, and although four prizes had been offered, they were increased to six to recognise the merit in the collections shown by the numerous competitors.

The collections of hardy flowers provided a mass of colour in another tent, and here again an extra prize had to be given. The 1st prize was won by Messrs. WM. ARTINDALE & SON.

Very effective trade groups were put up by Messrs. KENT & BRYDON, Darlington, and by Messrs. J. LAWRENCE & SONS, Scarborough, each of whom was awarded a Silver-gilt Medal.

There was only one group of Orchids staged, that by Mr. JOHN ROBSON, but this attracted much attention.

The 1st prize for a collection of six dishes of ripe fruit was taken by Mr. C. CROOKS, of Hadzor, Droitwich.

There were also classes for Melons, Peaches, and Tomatos, which were well competed for.

The show proved to be an exceedingly pretty one, and was held under almost ideal conditions; but the strong counter-attraction of the inspection of the warships had a great effect on the attendance. In spite of this, however, it is probable that the hospital funds will benefit to the extent of about £250.

CARDIFF & COUNTY HORTICULTURAL.

JULY 25 & 26.—The annual show was held in the Sophia Gardens, Cardiff, on the above dates in delightful weather. The show was one of the largest held by the society, and the exhibits generally were of the highest order of merit. The arrangements, carried out by the executive committee and their energetic secretary, Mr. H. Gillett, both for the exhibitors and the general public, were admirable.

In the class for a group of miscellaneous plants, occupying 150 square feet, and in which competition was keener than it has been for several years, Messrs. J. CYPHER & SON were awarded the 1st prize, H. OAKLEY, Esq., Caldicote (gr. F. Wood) being 2nd.

For a group of miscellaneous plants arranged to produce the best effect on a space of 50 square feet, Mrs. EVAN LEWIS, Llandaff (gr. G. Wall) took first honours, and J. HOWELLS, Esq., Cardiff (gr. A. Bloom) was 2nd.

Mrs. LEWIS was also awarded the 1st prize in a class for a group of the same size, from which Orchids were excluded.

The only collection of tuberous Begonias to occupy a space of 40 square feet was shown by W. GREEN, Esq., Cardiff (gr. J. Netford). The same exhibitor also obtained the 1st prize for six tuberous Begonias distinct, with very fine specimens; 2nd, W. EDWARDSON, Esq.

For six plants suitable for table decorations, S. WHITE, Esq., Clifton (gr. J. P. Bruce) was 1st, and Lady HILL 2nd. For six table plants distinct Mr. WHITE was again 1st.

For specimen Fuchsias exhibited in pots not exceeding 18 inches in diameter, Mr. G. N. NURSE was 1st.

Roses were shown exceedingly well, considering the unfavourable weather just previous to the show. In the class for twelve distinct varieties, three blooms of each, and twelve blooms, distinct, of Tea or Noisette varieties, Messrs. J. JEFFERIES & SONS, Cirencester, was 1st with a very clean lot; 2nd, the KING'S ACRE NURSERY CO., LTD., Hereford.

For eighteen blooms of Tea or Noisette Roses, Messrs. J. JEFFERIES & SONS were against 1st, and for twenty-four distinct varieties.

Messrs. JEFFERIES & SONS were awarded the Royal Horticultural Society's silver medal for the best exhibit in the above classes.

In the class for the best collection of Roses shown with their own foliage and buds, and occupying a space of 9 feet by 4 feet 6 inches, the competition was very keen; 1st, Mr. J. C. CROSSLING, Penarth; 2nd, Mr. J. MATLOCK, Oxford; 3rd, Mr. W. TRESEDER, Cardiff.

Carnations and Picotees in a class for twelve blooms distinct were very well shown by Messrs. BLACKMORE & LANGDON, Tiverton; 2nd, Mrs. BROOKS SMITH, Marychurch, Devon. For six vases of Carnations and Picotees, distinct, shown with their own foliage, Messrs. BLACKMORE & LANGDON were again 1st, and Mr. W. J. GODFREY 2nd. For the collection of Carnations and Picotees shown with their own foliage and occupying a space 6 feet long by 3 feet, Messrs. BLACKMORE & LANGDON and Mr. J. GODFREY again won 1st and 2nd prizes in this order. The best collection of hardy flowers was shown by Mr. W. TRESEDER, and the best twelve vases of flowers cut from herbaceous plants came from General LEE, Dinas Powis (gr. W. Horne).

Sweet Peas made a fine show, and occupied the greater part of two large tents. For nineteen varieties distinct, shown with their own foliage, Mr. THOMAS JONES, Ruabon, won the 1st prize, and Mr. HENRY PITT, Abergavenny, was 2nd. Mr. JONES also won the prize given by Mr. R. Sydenham for twelve distinct varieties, and the prize given by Mr. Henry Eckford for the best twelve distinct varieties of Eckford varieties. For six varieties, distinct, Mr. T. JONES won the 1st prize with the varieties—John England, Mary Malcom, Dora Breadmore, Henry Eckford, Helen Lewis, and Dorothy Eckford.

DECORATIVE SECTION.

The 1st prize for a dinner table 8 feet by 4 feet completely laid for six persons was exhibited by Mr. W. TRESEDER, Cardiff, who had a beautiful arrangement of Cattleyas, Odontoglossums, Oncidiums, etc.; 2nd, Messrs. CASE BROTHERS, Cardiff.

Mr. W. TRESEDER had the best hand bouquet, lady's bouquet, bouquet of Roses, two baskets of flowers, single basket of flowers, and lady's spray.

FRUIT.

There was a good display of fruit, all classes being keenly contested. For six dishes of dessert fruits, the Rt. Hon. W. H. LONG, M.P. (gr. W. Strugnell) won the 1st prize with Alicante Grapes, Sea Eagle Peach, Holborn Favourite Melon, Brown Turkey Fig, Humboldt Nectarine, and Large Early Apricot. Mr. H. PITT, Abergavenny, was 2nd. For two bunches of black Grapes, Rt. Hon. W. H. LONG was again 1st.

Vegetables were good all round, the best being shown by Lord ALDENHAM.

TRADE EXHIBITS.

Gold medals were awarded to Messrs. SUTTON & SONS, Reading, for a group of Gloxinias; Messrs. BLACKMORE & LANGDON for cut Begonias; the KING'S ACRE NURSERY CO., LTD., Hereford, for a collection of fruit-trees in pots; Messrs. J. JEFFERIES & SONS for a group of Conifers; Mr. MAURICE PRICHARD, Christchurch, for hardy flowers; Mr. HENRY ECKFORD, Wem, for Sweet Peas; and Messrs. DOBBIE & CO., Rothesay, for Pansies and Violas.

Silver medals were awarded to Messrs. GARRAWAY & CO., Clifton, for hardy flowers; Messrs. DICKSONS, LTD., Chester, and Mr. N. LEWIS, Bridgwater, for hardy flowers, and Mr. VINCENT SLADE, Taunton, for Pelargoniums.

Bronze medals to Mr. A. LL. GWILLIM, New Eltham, Kent, for Begonias; Messrs. JARMAN & CO., Chard, for Centaureas, etc.; and Mr. W. J. GODFREY, Exmouth, for a miscellaneous exhibit.

DURHAM, NORTHUMBERLAND, AND NEWCASTLE HORTICULTURAL AND BOTANICAL.

JULY 25, 26, 27.—This show was held in conjunction with the Northumberland Agricultural Society's show in ideal weather, and there was a record attendance, at any rate, on the first two days. The show was one of the finest ever seen in Newcastle. The competition in almost all the classes was very good, and the exhibits were excellent. The chief feature was constituted undoubtedly by the Roses, those shown by Messrs. HUGH DICKSON, of Belfast, in the collection arranged for effect being of exceptional merit. Worthy of note also were the specimen stove and greenhouse plants in flower, which displayed remarkable cultural ability. When it is considered that all the best plants were grown by enthusiastic pitmen, whose occupation only permits of limited time for the care of their plants, the exhibits were the more praiseworthy. The groups for effect were not so numerous as formerly, and the quality of them was below the usual standard. The hard-working new secretary, Mr. J. Wilfred Pace, and his assistants are to be congratulated, and the larger and more roomy tents secured by the council aided the better display of exhibits.

In the open classes, that for a group of miscellaneous growing plants was won by Messrs. ORD BROTHERS, Newcastle, Messrs. LIDDONS being 2nd. For six specimen stove and greenhouse plants, Mr. J. ELLISON, Cramlington, was 1st, the fine plants of Allamanda grandiflora, Stephanotis, Bougainvillea, Rondeletia, and Clerodendrons being excellent. Mr. E. GARDINER, Dunston, was a close 2nd.

For six table plants, Mr. J. C. McPHERSON (gr. to the Earl of Londesborough), Market Weighton, was 1st, and Mr. J. TRANTER, Hexham, 2nd. In the class for a collection of Roses arranged for effect, Messrs. HUGH DICKSON were 1st, and Messrs. J. COCKER & SONS, Aberdeen, 2nd. For thirty-six Roses in twelve distinct varieties, Messrs. ALEX. DICKSON & SONS, LTD.,

Newtownards, were 1st, and Messrs. HUGH DICKSON 2nd. For forty-eight blooms in twenty-four distinct varieties, Messrs. HUGH DICKSON were 1st; and for twenty-four blooms in twelve distinct varieties, Messrs. A. DICKSON & SONS. For the best twelve Roses of any one variety of H.P., Messrs. SIMPSON & SONS were 1st, and for twelve Tea Roses of one variety.

For twenty-four bunches of herbaceous and border flowers (Roses excluded), Messrs. HARKNESS & SONS, Bedale, were 1st. The best eighteen bunches of hardy flowers were shown by Messrs. GIBSON & Co. For six specimen glasses, each containing six blooms of Carnations, Messrs. J. THOMPSON & SON won the 1st prize. The cut flower classes were all well filled, and there were some close competitions for the bouquets and baskets of cut flowers, &c.

In the fruit classes, it is worthy of note that local exhibitors were particularly successful. This is the more encouraging when it is considered how few of them had previous experience in exhibiting. For a collection of eight dishes of fruit, Mr. J. C. MCPHERSON was 1st with fine dishes of Grapes, Apples, Pears, Peaches, and Nectarines; Mr. J. TULLETT, Raby Castle Gardens, was 2nd.

For four dishes of fruit (Pines excluded), Mr. J. TULLETT won the 1st prize, and Mr. MCPHERSON was 2nd. For four bunches of Grapes, in not fewer than two varieties, Mr. W. ROME, gr. to C. Bewick, Esq., Close House, Wylam, was 1st with fine examples of Muscat of Alexandria and Black Hamburg; Mr. J. TULLETT was 2nd. For two bunches of White Muscat, Mr. W. MARK was 1st; and for two bunches of any other white Grape, Mr. MCPHERSON. Mr. W. MORGAN, gr. to Sir W. Eden, Wendlestone Hall, had the best two bunches Black Hamburg; and Mr. BELL the best two bunches Black Grapes any other variety, with fine bunches of Madresfield Court. Melons, Peaches, Nectarines and Tomatos were also shown well. In a class confined to cultivators residing within three miles of Newcastle for four dishes of fruit, Mr. BRIGGS won the 1st prize.

The best collection of eight distinct kinds of Vegetables was shown by Mr. R. ELLIOTT; and in Messrs. Sutton & Sons' class for six distinct kinds, Mr. KEITH was 1st.

In Mr. Robert Sydenham's competition for a collection of Sweet Peas, Mr. KEITH was an easy first. This class was one of the most attractive features of the exhibition. The whole of the amateur classes were keenly contested, and the display was in every way satisfactory.

There were trade groups (not for competition) from Messrs. J. BACKHOUSE & SONS, LTD., York (Gold Medal); Mr. J. FORBES, Howick (Silver Medal); Messrs. CUBRANS, Altrincham; and Messrs. LAING & MATHER, Kelso.

NATIONAL CHRYSANTHEMUM.

VISIT TO DORKING.

JULY 23.—The members held their annual outing on Monday, July 23, when a visit was paid to Dorking. The party, which numbered about 100, on arrival at Dorking Station at once proceeded to Deepdene. By kind permission of her Grace Lily Duchess of Marlborough, a full tour of these beautiful gardens and grounds was made under the guidance of Mr. F. Chamberlain, the head gardener. The Orchid houses were a centre of attraction, and great admiration was also expressed for the terrace in front of the house, which was very tastefully laid out. The greenhouses and gardens were extremely well kept and reflected great credit on Mr. Chamberlain.

At one o'clock the members proceeded to the Wheatsheaf, High Street, Dorking, for dinner, the chair being occupied by Mr. Thomas Bevan, the chairman of the Society.

The opportunity was then taken of presenting to Mr. G. R. Dean and to the Misses Dean the medals of the Society which had been voted by the executive committee in appreciation of their valuable services both during the secretaryship of their late father, Mr. Richard Dean, and also since his death in August last. Mr. G. R. Dean suitably acknowledged the presentations on behalf of himself and his sisters.

Mr. J. H. Witty, the vice-chairman of the Society, also announced that it was intended to perpetuate the memory of the late secretary by creating a "Dean Memorial Medal," and appealed for subscriptions towards that object. The thanks of the members were then expressed to Mr. J. T. Simpson for his labours in organising the day's outing.

In the afternoon the party drove to Broome Hall, where a halt was made to enable the members to inspect these grounds, the necessary permission having been granted by Sir Alexander Hargreaves Brown. The party were met by the head gardener, Mr. C. Fulchey. The carriage drive was planted with beautiful shrubs in great variety, whilst on the terrace in front of the house were to be seen some magnificent standard Portugal Laurels. On the sides of the carriage road were splendid specimens of Coniferæ, notably Cedrus atlantica glauca, Abies, and Piceas in great variety. The drive was subsequently continued to Ockley, and thence round Holmwood to Dorking, and the party returned to London at 8.30.

ENQUIRIES AND REPLIES.

RICHARDIAS.—Amongst a batch of Richardia Elliottiana, grown from own saved seed, I have one plant quite different from the rest; the leaves are spotted like Elliottiana, but the stems are not mottled like that variety, but are plain green. They are long and shaped like an arrowhead. The flower is white, with a narrow band of violet colour at the base of the bloom inside, not visible outside. Is there any variety coloured exactly like mine? If not, has it any value as a new variety? At the time of saving seed I only had two varieties, the one named and R. africana, so the cross to me seems peculiar unless it has reverted to one of the parents of R. Elliottiana which I am not acquainted with. *Arum Lily.* [The variety is an instance of variation in a seedling, but it is unlikely that it is due to the parent having been crossed with R. Africana, if you have made no attempt to do this. Without seeing the plant we cannot express an opinion as to its distinctiveness, and certainly not its financial value, but it would be interesting to save seeds from it in order to see what variation there will be in the second generation.—ED.]

TEA.—Where can I purchase growing Tea plants (Ceylon or Indian), and what is the market price for them? *Tea Plant.*

THE KEEPING OF APPLES. Can anyone say if it would be possible to keep Apples with any degree of success in the same way (stored in tins and buried in the earth) as advised lately for Potatos. We grow some of the best Apples that are produced in this neighbourhood, but our fruit-room is not one of the best, and we find the late varieties shrivel to such an extent that by Christmas, or before, we have not a good fruit left. Any suggestion would be much appreciated by "*Taylor, Somerset.*"

ANSWERS TO CORRESPONDENTS.

CARNATIONS: *J. E. M.* Judging from the specimens received which were slightly withered, we do not think the variety is superior to existing sorts. You are right in supposing that the seedling might be submitted to the inspection of the Royal Horticultural Society's Floral Committee, but the next meeting will not be held until August 14, in the Royal Horticultural Hall, Vincent Square, Westminster. In any case you would do well to cultivate the plants for another season.

DISQUALIFICATION AT EXHIBITIONS: *E. W.* Presumably you were disqualified for showing two species of plants, in the place of one plant, in one pot, when the schedule asked for six plants distinct. We do not think you have any right of complaint. In respect to the other case you mention, it is necessary to remember that although Oranges are fruits they are borne on plants, and if fruit-bearing plants were not excluded from the class by words inserted in the schedule, the judges would not have acted wisely in disqualifying the Orange tree.

FIGS: *C. J. B.* Your fruits are affected with a fungus, Cercospora Bolleana. Burn the affected fruits and leaves, and spray carefully with Bordeaux mixture.

GARDENER'S NOTICE: *Anxious Reader.* We think you are entitled to a month's notice. Gardeners should always have an agreement on this matter when taking up a situation.

GRAPES: *Mack, Yorks, and F. P., A Subscriber.* There is no fungus disease present. The injury has probably been caused by chill when a deposit of moisture was present on the berries. *East York.* Your grapes are affected with the "Spot" disease (Gloeosporium ampelophagum) so often described in these columns. Burn the affected berries. Next year spray the young bunches with liver of sulphur (½oz. to a gallon of water), taking care not to wet the paint.

LILY DISEASE: *W. H. C.* Syringe the plants thoroughly with a solution consisting of one wineglass of formalin mixed with two gallons of water.

NAMES OF PLANTS: *H. V.* Ailanthus glandulosa.—*J. G.* Convolvulus japonicus albus, otherwise Calystegia pubescens.—*L. C.* From last week. 1, Senecio Fuchsii, Gmel; 4, Teucrium polium, L.—*M. A. W.* 1, Begonia—not recognised; 2, Aristolochia elegans; 3, Gnaphalium margaritaceum; 4, Catananche cœrulea; 5, Adiantum Capillus Veneris imbricatum; 6, Adiantum Weigandi.—*W. F. H.* Spartium junceum.—*Glasgow.* A variegated form of the common Elm Ulmus campestris.—Strawberry next week.—*J. Miller.* Polystichum aculeatum, as far as can be determined from the poor specimen.—*J. M. F.* 1, Gnaphalium margaritæum; 2, Œnothera Youngi; 3, Cimicifuga racemosa; 4, Sidalcea malvæflora; 5, Sidalcea malvæflora var.; 6, Tradescantia virginica alba.—*C. H. P.* Ptelea trifoliolata.—*G. F. J.* Acer Negundo.—*J. C.* Mutisia decurrens.—*Old Subscriber.* The Orchids next week; the shrub is Leycesteria formosa.—*G. H. S.* 1, Cassinia fulvida; 2, Spiræa callosa; 3, Veratrum nigrum; 4, Inula Helenium; 5, Lysimachia clethroides; 6, Cistus ladaniferus; 7, Silene Armeria.—*S. W.* Pancratium maritimum.—*Flora.* Lathyrus magellanicus (Lord Anson's Pea).—*H. A. H.* Mandevilla suaveolens.—*F. H.* We cannot undertake to name varieties of Carnations. Send them to a nurseryman who grows them in considerable numbers and where they may be compared with living specimens.

PEACHES: *Sir B. S.* The fruits were very fine ones of the variety Royal George, but suffered considerable bruising in the post. This variety very seldom develops much colour.

PEAS: *Kerry.* Your Peas are badly attacked with Pea mildew. You can do nothing this year. Do not sow on the same ground next year.

PELARGONIUMS: *Caution.* The Pelargonium cuttings appear to have been planted too deeply. The coloration of the leaves is an indication of approaching decay.

ROSES: *J. S. U.* The appearance of the Rose buds would seem to indicate that the weather in your district has been uncongenial, and against the proper development of the flowers. There are signs also of mildew. Beyond this, however, we have not discovered any disease in the specimens received.

TOMATOS: *R. D.* The fruits are badly attacked with the fungus Cladosporium Lycopersici, frequently described in these columns. You will find a description and illustration of fruits similarly attacked in *The Calendar of Garden Operations*, which can be obtained from our publisher, price 7½d. post free.

TREE CARNATIONS: *J. D. C.* See article in our issue for June 30 last, p. 417. There is also a book to be obtained entitled *The American Carnation.*

GUNNERSBURY HOUSE, ACTON.

THERE is a natural beauty in the undulating character of the grounds around Gunnersbury House, visited on Friday, August 3, by the members of the Plant-Breeding Conference. This natural beauty, however, has gained very much from the many years of clever development by Leopold de Rothschild, Esq., who, for the past 28 years, has had Mr. James Hudson, V.M.H., as his head gardener. This development has brought out many charming garden effects, whilst many new garden scenes have been added, each complete in itself. It is, therefore, at the present time a garden of gardens, and is decidedly more interesting than one lacking so many features could possibly be.

Some of the pretty nooks are worked out from Mr. Leopold de Rothschild's own designs, as, for example, the pretty little country Swiss Garden, with sundial in the centre, the idea for which was obtained in a quiet Swiss retreat. More often the new gardens result from conferences with Mr. Hudson, who always superintends every detail of the work. The incentive for making the new and dissimilar gardens on the borders of the pleasure grounds is that no uninteresting nook shall be allowed. Whenever one such is adjudged to be not doing its share in adding to the beauty or interest of the garden it is made to illustrate some new creation of the gardener's art. Thus a plain brick wall has been transformed into the semblance of a ruin of an old castle. The ancient-looking windows, door, niches, and corner tower are now beautified by a host of pretty and fragrant plants in bloom.

At the end of the "ruin" are the tanks, slightly heated from the overflow of the warmhouse Lily tanks, and in which are acclimatised the handsome blue Nymphæa stellata, Berlin variety, now flowering in great profusion. In point of beauty, however, the enormous blue flowers of N. gigantea Hudsoni, raised at Gunnersbury, whose lovely blooms stand a foot or so above the surface of the water, are by far the best.

In the lake beyond, on the margin of which are immense clumps of Bamboos and other tropical-looking plants, the white, yellow, rose, and crimson Water Lilies make a splendid show, some 50 varieties of different shades being now in bloom.

Then there is the Japanese Garden, with its wicket-gates, tea-houses, bridges, and seats of Bamboo cane, very large living specimens of which are interspersed. The gardens are most carefully designed after Japanese models, the stepping stones over the rocky ground and rivulets, and the Japanese lantern, the pigmy Conifers, profusion of Japanese Lilies, Iris, and the Japanese plants and shrubs constituting it quite an imitation of a Japanese garden, although the scene is laid within a short distance of the city of London. Beyond the Japanese garden is the newest feature—a Heath Garden (see Fig. 30), in which, in elevated patches, with a rock-sided, sunken walk dividing the two sections, are planted large quantities of all the best hardy Ericas. The work was commenced four months ago, and already bright patches of Erica cinerea rosea, Dabeocia polifolia, the white bells of D. polifolia alba, and the rosy tints of other Heaths give good effect, which will continue until all are in bloom. The rocky margins are planted with Alpine plants, Mesembryanthemums, and other bright flowers. From the lake a view of the mansion on the highest ground reveals a most brilliant display of scarlet Tropæolum, "Ball of Fire," which runs in three broad bands above the old museum, the terraces having large specimens, chiefly of Eastern trees, such as Pomegranates, Oranges, and Myrtles in tubs. Large scented-leafed Pelargoniums, Agapanthus, and other showy plants are always kept to change the arrangement of flowers on the terrace, and for autumn what might be called movable flower-beds, made up of 20 or 30 plants of Chrysanthemums planted in huge tubs, are found very useful.

At the end of one of the cool, shady walks is the Ivy Garden, in which all the varieties of Ivy are artistically displayed, the sheltered nook being pleasant at all seasons; beyond is a Rose Garden, the main bed in which is of Caroline Testout, some 600 specimens being used in the bed, which is beautifully set with flowers. Other Rose gardens and displays of pillar and trailing Roses follow, then a broad border of herbaceous perennials, and some pretty effects in mixed bedding. In one group Canna King Humbert has heads of large red flowers showing well above the bronzy leaves; in another the Heliotropes raised from seeds make a nice bed; the Pentstemons are bright and of fine quality, Impatiens Holstii of bright cinnabar scarlet colour, and at another point a brilliant display of flowers, chiefly annuals, is seen. Gerbera Jamesoni, the brilliant scarlet "Transvaal Daisy," has been acclimatised, and it makes one of the brightest of summer flowers. Those now in great beauty are seedlings raised from home-saved seeds. Near by the Gerberas are a group of other African bulbs—Crinum Moorei, C. longifolium, and the hybrid C. Powellii and its pure white variety all finely in bloom.

The Plant-houses

are devoted to the culture of showy flowers and of fruits, and the highest success is attained in each branch.

Several houses are filled with Orchids, including Odontoglossums, Cattleyas, Lælias, together with a large batch of hybrid Lælio-Cattleyas, etc. The show of flowers at present consists mainly of a number of the fine blue Vanda cœrulea and some Cattleyas and Lælias. The fine white Dendrobium formosum giganteum is one of the specialities of Gunnersbury House, where it annually makes a great show, and has been grown successfully without interruption for many years. So well is its culture understood that seedlings from imported seeds are germinating freely and making sturdy little plants. Habenaria militaris is sending up spikes of scarlet flowers, Phalænopsis Rimestadtiana has verified the statement that it is the most useful Phalænopsis by growing well and sending up fine spikes of large white flowers, and throughout all the houses the best evidence of good culture is given.

The ranges of vineries, with their heavy crops, tell the same tale of success, a house of varieties of Frontignan, which are favourites with Mrs Leopold de Rothschild, being an unusual sight. Alpine Strawberries are also favourites, and these are grown from seeds. Of the larger varieties of Strawberry which have fruited well this year is a batch which had fruited in April, now being rested to fruit again in September. The Fig-houses are well cropped, and each house has to perfect two sets of Figs in pots each year. As an instance of prolonged good cropping is a tree of Nectarine Lord Napier planted in the house by Mr. Hudson 28 years ago, and which has been always relied on for a crop, the number of fruits borne by it this year being recorded as 350.

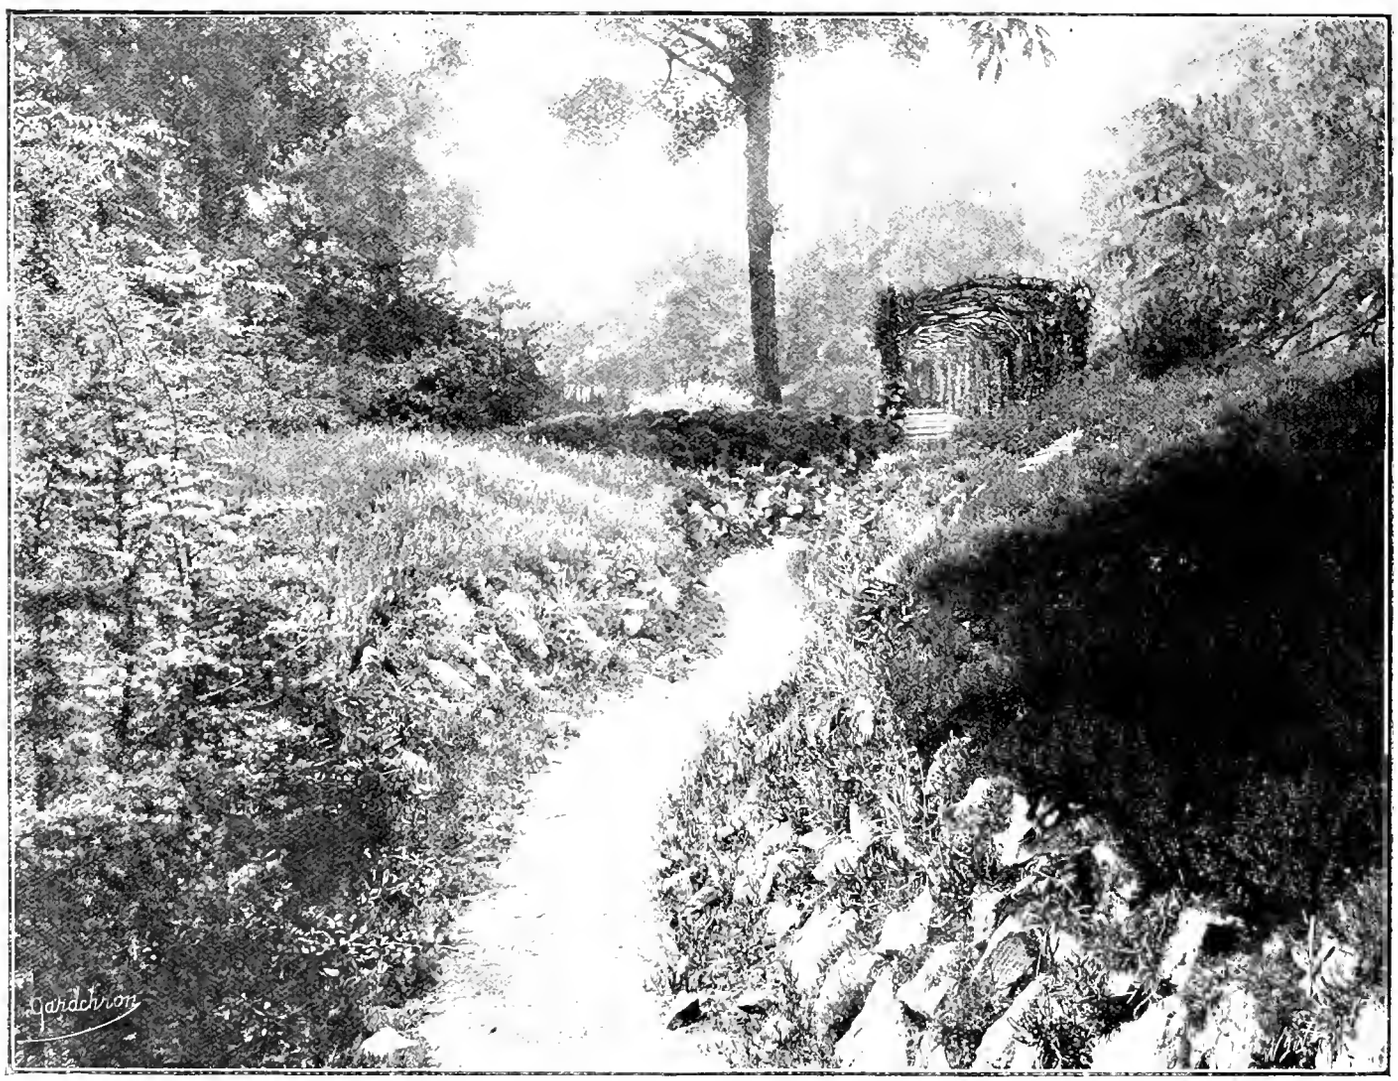
A visit we paid previously to these gardens afforded fresh proof of the satisfactory results obtainable from the cultivation of fruit trees in pots. It is some years since Mr. James Hudson was encouraged by his employer to take a leaf out of the book of Messrs. Rivers and Son, and to try and cultivate specimens of pot fruit-trees similar to those which that firm had

been in the habit of exhibiting at the Temple and other shows. Many of our readers have probably been able to judge from the collections of trees since exhibited publicly from Mr. de Rothschild's garden how apt a pupil Mr. Hudson has proved in this particular branch of cultivation, and we say pupil advisedly, for Mr. Hudson readily acknowledges his indebtedness to Messrs. Rivers for the many useful hints they have given him, and confesses to have imitated their system pretty closely. But it has to be pointed out that experience so necessary in all departments of garden practice is particularly helpful in the cultivation of pot fruit-trees. Consequently the results are

sists of 1,200 trees would cause surprise, for the houses appear to be inadequate for so large a number. Two advantages claimed for this system seem to us undeniable; it affords the opportunity to cultivate in a given space more varieties of each kind of fruit than any other system, and it affords the means of obtaining a longer succession of a particular kind of fruit. Appearances would indicate also that in each house a greater weight of fruit can be ripened than would be possible if stationary trees alone were cultivated. As a set-off to all this it must be admitted that trees in pots give much more trouble than trees in borders, and considerable labour is involved by the necessary

but they are not necessarily put into pots of larger size. Unless it is wished to grow them into larger specimens, the plants are taken out of the pots and sufficient soil is taken away from the roots to allow of fresh soil being rammed all round, and a good layer put over the crocks, even when put into pots of exactly the same size as those from which they were taken. In addition a moderately rich top dressing is applied during the season of growth, generally when the stoning period has been reached

But it is not our present intention to enter into details, for Mr. Hudson has been good enough to write a full account of the system of cultivation he practices, from the building



[*Photo by John Gregory.*

FIG. 39.—THE NEW ERICA GARDEN AT GUNNERSBURY HOUSE.

more satisfactory each year, and we need offer no excuse for again drawing attention to the subject.

As we observed the trees laden with Cherries or Plums, Peaches or Nectarines, and saw the comparatively small amount of house accommodation that exists for the very large number of trees that ripen their fruits therein, we were impressed with the economy of the system, and it would be interesting if Mr. Hudson could tell us how many fruits are obtained from each house in one year. Until it is realised that the trees fruit in succession, and that at all seasons of the year there are many of them out of doors, the statement that the collection now con-

removal of the trees into or out of the house as they are needed for forcing, or when they have ripened their fruits.

There used to be a general idea that fruit trees so cultivated, and therefore suffering the restriction which is essential to the system, were short lived, and even that they were only profitable for very few seasons. We have referred on many occasions to the contrary experience of Messrs. Rivers in regard to this matter, and Mr. Hudson has had similar results. The first trees he purchased are at the present time as fruitful as ever, and give every indication that they will remain so for an indefinite time. The trees are repotted every year without exception,

of suitable houses to the ripening of the fruits, and our readers will shortly have the opportunity of reading this in these columns. It may, however, be pointed out that at Gunnersbury the different successions of fruit necessitate the houses being used for the accommodation of the trees in most instances throughout the year. Early potted trees for early forcing follow the late trees at once. Figs follow the second early trees and others, and nearly complete the entire round of the year. The house is only used otherwise for October and November Chrysanthemums. Melons and Tomatos fill up any spare room. In the Strawberry houses Figs follow at once. The

trees that were fruiting at the time of our visit were heavily cropped, and even those that had yielded their fruits bore testimony of what they had done, for on the labels appeared the numbers "15," "18," or "20," indicating the crop of Peaches or Nectarines that had been gathered from the specimens. We know that more gardeners cultivate fruit trees in pots than was the case formerly, but the system is deserving of so much wider adoption that Mr. de Rothschild does a public service by exhibiting the excellent results obtained in his Gunnersbury garden. Mr. James Hudson, of whom we present our readers with a photograph (p. 105), is a member of the Council of the Royal Horticultural Society, and what may be even more interesting, he was the first student who obtained the maximum number of points at a R.H.S. Examination.

(For text see page 101.)

A METHOD OF CULTIVATING STRAWBERRIES FOR FORCING.

THE keynote to success in Strawberry forcing is to have a good supply of early potted plants on hand, with the fruiting pots full of roots by the end of September, and crowns well in evidence before the winter comes on. The Strawberry in a pot, intended for forcing in the spring, does more than half its work before the growing season of the previous year is over, but unless it be given facilities for so doing, one might just as well save the space which it will occupy under glass later on. Plants which have not practically completed their growth in the autumn are next to useless.

The plan usually adopted by forcers of Strawberries is to take the runners of the current year direct from the bed during the months of July and August, or, better still, to layer them into small pots while they (the runners) are still attached to the parent plants, the suckers being severed and the pots removed so soon as the young plants are properly rooted. The plan is good enough so far as it goes, and indeed the method could hardly be improved upon if it be desired to force the plants in their first season. An attempt will be here made to explain a much more satisfactory method of Strawberry forcing, and one which, although it entails longer waiting for the crop, is infinitely cheaper and productive of far better results in the end than any other practice hitherto adopted.

The mode of procedure is as follows:—After the outdoor Strawberry crop is over and the annual cleaning of the beds has been begun, a number of plants, sufficient to yield the requisite number of young plants required, should be left untouched so far as the trimming off of suckers is concerned, and allowed to root their runners into the soil. The ground should of course be kept clear of weeds, and a slight breaking up of the surface to enable the young plants to get a better hold will be advantageous. No further attention is now needed except the stopping of the suckers when they have rooted one, or at most two, sturdy plants. It is as well to bear in mind at this stage of the proceedings that the plants which produce the most suckers are very often the least fruitful. An endeavour should therefore be made if possible to mark the plants which during the past season are known to have cropped well. This knowledge, although it is not absolutely essential, as will be shown later on, will make assurance doubly sure and enable one when the time comes to select only the progeny of the most fruitful plants on the bed.

Beyond an occasional look round to see that the young plants are free from weeds and have plenty of room all round them, they will now need no further thought or care until the period of blossoming arrives in the following spring. The work of selection now begins, and the plants should be carefully gone over so soon as the bloom-trusses appear. All blind or weakly-looking plants should be ruthlessly destroyed, and only those which show promise of abundant fruitfulness be allowed to remain. They must not, however, be permitted to blossom, but each bloom-truss, before it opens, must be carefully removed. If the season be a dry one, an occasional watering, with shallow surface cultivation, will improve the vigor of the plants, which at this time will be concentrating all their strength on the development of roots and leaves.

When July arrives the first real labour in connection with the plants begins, for they must be lifted bodily with a good ball and established firmly in their fruiting pots by the end of the month, or at least by the second week in August. The pots required will be either 32's or 24's, according to the vigour of the plants, but the latter size will in all cases be quite large enough. Let the compost be a good, firm loam, with a liberal admixture of sand and about one part in five of well-rotted cowdung to ensure quick rooting. If carefully lifted the plants need receive no check whatever, but it is essential that, if the weather be dry and the soil hard, a good watering be given two or three hours before lifting.

The rest of the procedure is exactly the same as in the case of ordinary forcing, and it will be found that these year-old plants, which have never been allowed to fruit, will yield a far heavier crop than any runners of the year, however carefully selected and subsequently treated. But there are other advantages in connection with this improved system. The chief of these is that the possibility of blind plants being selected is totally removed, a very important consideration when a large number of plants is forced and house room is at a premium as it usually is in winter time. The percentage of blind plants is by no means inconsiderable on an average, and if these can be left out at the planting, the advantage in room saved is obvious.

Then, again, all the labour of potting up, moving, and constant watering of unproductive plants is entirely done away with, to say nothing of the extra amount of water and fertiliser generally expended upon blind plants before their defects are discovered. There is, indeed, so far as one can see, no single drawback to the improved system, unless it be that the crop hangs about for a couple of seasons instead of only one. But that drawback, seeing that very little extra labour is involved thereby, is well outweighed by the many advantages of the system. *East Sussex.*

REMARKS ON THE CONDITION OF THE FRUIT CROPS.

(See Tables and Summaries, ante, pp. 64-70.)

(Continued from page 87.)

4. MIDLAND COUNTIES.

BEDFORDSHIRE.—East winds, with the temperature ranging from 25° to 35° during the months of March and April, seriously affected stone fruits, but Apples, Strawberries, and Black Currants are record crops. The soil here is of gaulty clay. *H. Nimmo, Cranfield Court Gardens, Woburn Sands.*

—— The fruit crops are very fair all over Bedfordshire, with the exception of Plums and Pears. I may say this, having had an opportunity on Tuesday and Wednesday, July 17 and 18, of seeing the country from Bedford, Shifford, and Luton, to Hitchin. *George Mackinlay, Wrest Park Gardens.*

BUCKINGHAMSHIRE.—With the exception of Plums and Sweet Cherries the fruit crop here is a good average one. The Plums and Sweet Cherries were very full of promise, but the frosts in April and May destroyed almost the whole of the bloom. Pears fell off when small, being much damaged by frost. There is, however, a good sprinkling of fruit upon most trees. Peaches and Nectarines, Black and Red Currants are good. Strawberries have been abundant and good. *John Fleming, The Gardens, Wexham Park, Slough.*

—— The cold east winds and frost ruined the Pear and Plum crop. The Pear midge also did much damage. *Chas. Page, Dropmore Gardens, Maidenhead.*

—— All fruit trees bloomed fairly well, but the late spring frosts seriously affected the greater portion of the fruit crops in this district; some orchards are absolutely devoid of fruit. Peaches on walls suffered terribly from frost on the night of April 27, some of the wood being killed outright fruits nearly half an inch in diameter were frozen to the centre. Most orchard trees are badly infested with black fly, and in some cases mildew. *W. Hadley Warren, The Gardens, Aston Clinton, Tring.*

—— Frosts, which averaged from 3° to 6° from April 24 to April 30, most seriously affected the fruit crops in the present season. *James MacGregor, Mentmore Gardens, Leighton Buzzard.*

DERBYSHIRE.—The present season's crops were badly affected by continued cold weather during the blooming period, and by extreme drought since. The season has been peculiar in the fact of continuous cold nights without any severe frosts. The thermometer has fallen below 40° Fahr. many times this month (July), and this is only a continuance of the general conditions for months past. *J. C. Tallack, Shipley Hall Gardens, Derby.*

—— Apples are an abundant crop. Pears, Plums, and Apricots are much below the average. Red, White, or Black Currants are plentiful and good. Gooseberries and Raspberries are a good average crop. Strawberries from young plantations were large and of good flavour. Fruit from the older plantations are plentiful but small, and have not ripened well. The soil here is from medium to heavy, resting on gravel. Spring frosts have most affected the fruit crops this season, especially Pears and Plums. *James Tully, Osmaston Manor Gardens.*

HERTFORDSHIRE.—Twelve degrees of frost on April 20 and frequent sharp frosts to the end of the month destroyed the stigmas on every unopened bloom, whether of Apple, Pear, Plum, or Cherry. The soil is a strong loam; sub-soil clay 3 feet, resting on sand. *C. R. Fielder, The Gardens, North Mymms Park, Hatfield.*

—— The first week in July is favoured for summer pruning of hardy fruit; attention is given to laying in suitable growths of stone-fruits at the same time. The general result is good where it is properly done and the characteristics of the various varieties considered. The exceptional mild winter and ungenial spring with sharp frosts almost every night, together with subsequent drought are accountable for the thinness of the fruit crops. The soil in this district is a light loam upon a gravel subsoil; it also embraces a heavy land upon a bluish-grey clay subsoil. *F. W. Gooch, The Gardens, Edge Grove, Watford.*

—— Continuous severe frosts during April and May ruined the crops. The soil is a strong clay. *Edwin Beckett, Aldenham House, Elstree.*

—— In common with the cultivators in most counties, we who live in Hertfordshire have to lament the effects of frost and cold winds that were prevalent quite late in spring. Apples are a good, average crop, but Plums and Pears are exceedingly few. *J. C., Watford.*

Photo by C. Henwood.

FIG. 41.—STEPPING-STONE PATH THROUGH BAMBOO AVENUE AT GUNNERSBURY HOUSE.

(For text see page 101.)

—— The circumstances that have most affected the fruit crops in the present season are spring frosts. *Thos. Rivers & Sons, Sawbridgeworth.*

—— The very cold nights while stone fruits were in blossom completely destroyed our hopes of getting good crops, and with the exception of a good crop of Cherries and a very moderate one of Peaches, stone fruits are quite a failure. Small fruits are a good crop, and the quality is good, while Strawberries have been good in both quantity and quality; nuts are few and poor. *H. Prime, Hatfield House Gardens.*

Leicestershire.—The severe frosts in April during the time stone fruits and Pears were in flower, and the cold north-east winds which were almost continuous during the flowering season of the Apples, are the chief causes of the poor fruit crops in this district. The soil is loam on a subsoil of red clay. *D. Roberts, Prestwold Hall Gardens, Loughborough.*

—— The fruit crops were most injured by frost on April 27, when the minimum temperature on the grass was 18°, and at 4 feet above the surface, fully exposed, 24°. This destroyed half the crop of Gooseberries and Pears, all the Plums on standard trees, also the Damsons. Strawberries and Apples were not in flower, and thus escaped injury. The soil was stiff clay 100 years since, but has been improved by various additions; subsoil clay of the middle lias system. *W. H. Divers, Belvoir Castle Gardens, Grantham.*

Northamptonshire.—Apples, Pears, Plums, and Strawberries all suffered from frosts during the flowering stage. Gooseberries were practically ruined by frost on May 18 when they were almost ready for gathering. Strawberries have suffered much from mildew, following a severe thunderstorm on June 30. *R. Johnston, Wakefield Gardens.*

Nottinghamshire.—The prospects of a good Pear and Plum season were entirely spoiled by the late frosts. When in full blossom heavy rain, followed by 8° of frost on one night completely ruined the crop. *James Gibson, Welbeck Gardens, Worksop.*

—— All our fruit crops are up to the average except Plums, which were badly injured with frost. Being sheltered we get less frost here than is experienced in neighbouring gardens. *James B. Allan, Osberton Gardens, Worksop.*

—— The circumstance which most affected the fruit crops in the present season was the May frosts. The soil is red clay (Keuper marl). *J. R. Pearson & Sons, Chilwell Nurseries, Loughborough.*

Oxfordshire.—Had it not been for the late spring frosts fruit crops of all kinds would have been exceptionally heavy. *J. Broadfoot, Shotover Gardens, Wheatley.*

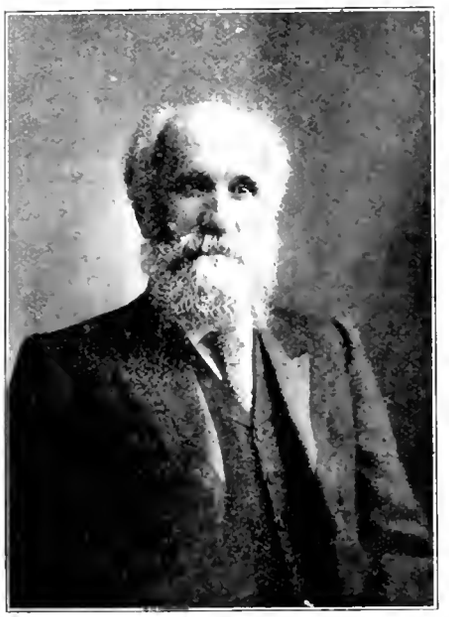
Shropshire.—The continuous north-east winds during April and May seemed to paralyse the fruit crops. On the whole I have a good half crop of Apples, but they are very irregular, some trees I have had to thin, while others have few or none. Of Pears there is only a sprinkling, Plums on walls are about one third of a crop, small fruits are nearly a failure, but Strawberries were a full average crop. *James Louden, The Quinta, Chirk.*

——Frosts in April did most damage to the blossom, especially the severe attacks (10°) on the night of the 26th and morning of the 27th, and when the trees were covered with snow and water, which was turned into ice (half-inch thick) in my garden. I never saw such injury to fruit trees. The most remarkable thing is that the Apple crop escaped so well. Cox's Orange suffered worst—much of the foliage being blackened, as well as the flowers. The soil is sandy loam, with gravel. *A. S. Kemp, Broadway, Shifnal, Salop.*

Staffordshire.—Adverse circumstances this season have been as follows: Apples have suffered from caterpillar; Pears from frost and black spot; Plums from frost and aphis; and red and black Currants from aphis. The surface soil is of stiff loam, and the sub-soil waterclay, interspersed with stones. *George Woodgate, Rolleston Hall Gardens, Burton-on-Trent.*

—— The sharp frost (8°) which occurred on the morning of the 27th April quite ruined the Damson and Plum crops, as the trees were in full bloom at the time, and snow and rain had fallen late on the previous night. The trees presented the appearance of a mass of ice the next morning. *John Wallis, Woore, Newcastle.*

Warwickshire.—The fruit crops are again grievously disappointing, more especially of Apples, Pears and Plums, yet the flowering was everything that could be desired. We have again the far too frequent visitation of spring cold, which no blossom, no matter how strong it may be, can withstand. There are, however, a few estates round here, Barston Hall for instance, the seat of John Roderick, Esq., where they are more favoured, very probably from their higher elevation. I noted at that place good average crops of such varieties as Irish Peach, Cox's Orange, Warner's King, Bramley's Seedling, Jolly Beggar, Newton Wonder, Ecklinville, and Worcester Pearmain Apples. On the Manor Fruit Farm at Knowle, belonging to Edward Tangye, Esq., there is a fair sprinkling of Apples for such a season on the young trees, which are in the best of health and vigour, and this year Mr. Tangye is highly optimistic as to the ultimate result of his Warwickshire venture; his land, which is fairly well sheltered, is of a light loamy texture, resting on a red marly clay formation, on which almost all fruit crops succeed well. Along the road we occasionally see a tree carrying a fairly good crop of fruit, and that is about all that can be said for this



James Hudson, V.M.H.
(See page 101.)

neighbourhood. On July 18 I had the pleasure of accompanying the Birmingham and Midland Counties Mutual Improvement Association in their outing to Batsford Park, the seat of Lord Redesdale; this necessitated a most interesting railway run through Worcester, Pershore, Fladbury, and Evesham to Moreton-in-the-Marsh. During the run through that fruit-famed district I saw nothing better in fruit, perhaps not even so good as we have it here, notwithstanding their warmer soils. The cause which brought about the general disaster to fruit crops was the extreme and continuous cold weather during the flowering period, against which the favoured warm geological formation of the old red sandstone rocks of either Worcester or Hereford, or even of the mixed geological formation of Gloucester, apparently, can afford no immunity, and it is exceedingly mortifying to British growers to find the warm sun of this lovely summer, as well as many others, is wasted on the production of only a crop of luxuriant leaves; whilst America, Canada, and other countries will be pouring their first supply into our markets, carrying away so much money, in which we, for this year at least, can have but small participation. Insect pests have this season been even more mischievous and troublesome than I remember them to have been; not only are they on our Roses, fruit trees, &c., but Oak woods in this neighbourhood, in what ought to have been leafy June, were at that time as naked and as free of leaves as they were during midwinter; they have now recovered, but I think there will be but few Acorns, as there were also last year. *W. Miller, Berkswell.*

Berkshire.—The present is our worst season for the past 20 years, owing to cold winds and late frosts. Our soil is very light, resting on gravel. *J. Howard, Benham Park Gardens, Newbury.*

—— There can be no doubt that the severe frosts experienced in May were primarily responsible for the failure of the Plum and Pear crops here. Most fortunately Apples and small fruits, together with Strawberries, were particularly backward at the time. The soil here is somewhat heavy and retentive, with subsoil of stiff clay. *Wm. Pope, Highclere Gardens.*

Dorsetshire.—The cold winds and frost in the latter part of May mostly affected the fruit crops in this district, but as our garden lays over 600 feet above the sea-level our trees are naturally later than most of those in the district, with the result that our bloom escaped damage. Aphis has been troublesome. Our soil varies, but is chiefly of a sandy nature, with chalky subsoil; in other parts subsoil is of green sand. *Harry Birkinshaw, Chaddington Court Gardens, Crewkerne.*

—— The frost on April 15, 16 and 17, viz., 9°, 8° and 6° respectively, killed much of the bloom on Pear, Plum and Sweet Cherry trees. But the frost on April 27, viz., 9°, finished the work completely on Pyramid Pears, Plums and Gooseberries. To frost alone I attribute the loss of these crops. The soil here is a heavy loam on rocky subsoil of varied depth. *T. Turton, Castle Gardens, Sherborne.*

— The fruit crops are much below average in this district, and this is mainly due to the very cold weather experienced in early May when the young fruits were tender. Apples with a few exceptions escaped and carry a fair average crop. Stone fruits of all sorts are under average. Plums, Peaches and Cherries have about half crops. Of Apricots there are none. Pears are half a crop, but the quantity is good and the trees are clean. The soil is a light loam and vegetable mould on loose sandy gravel. *Ben. Campbell, The Gardens, Kingston House, Dorchester.*

Hampshire.—The unpropitious circumstances this season were frost in April and May with long spells of cold, sunless weather, followed by drought in April, when the rainfall was but 0·63 for the month. Ours is a heavy retentive soil over a 2 feet pan of clay then chalk. *E. Molyneux, Swanmore Park, Bishop's Waltham.*

—— The frosts of April 14, 15, and 16, were the chief cause of the Plum, Pear, Apricot, and Gooseberry crops amounting as they do to little more than nothing. Our soil is stiff clayey loam on a subsoil of London clay. *A. G. Nichols, Strathfieldsaye Gardens.*

—— The failure of Pears and Plums this season is due to the severe frosts when the trees were in flower: during the month of April we registered a total of over 50° of frost, and on several nights in May we had 4° and 5°. Our soil is very light, resting on gravelly-clay subsoil. *J. Wasley, Sherfield Manor Gardens, Basingstoke.*

Kent.—Continued cold winds from the east when the trees were in bloom has most affected the fruit crops here in the present season. The soil is fairly stiff, with a subsoil of "pinnick." This latter is red, very stiff (much like clay), and is full of small stones. *G. Woodward, Barham Court.*

——Spring frosts—continued low temperature—both in the flowering and setting time, caused much destruction to all fruit crops, excepting Apples, which are partial, but splendid in our nurseries. Strawberries have been the best soft fruit crop where they escaped the May frosts. Our soil is sandy loam over Kent ragstone. *George Bunyard, Maidstone.*

——Probably the frosts on April 20, 24 and 26, and hail on the 26th were most harmful to Plums, Cherries and Pears. There was no frost while the Apples were in bloom. The following low temperatures occurred in April (Kew verification):—(Sheltered): 20, 32°, 24, 30.8°; 26, 32°, 29, 32.8°. (On Grass): 20, 30°; 24, 30.8°; 26, 29°; 29, 29°. The soil is a strong clayey loam, resting on the outcrop of the lower greensand or Kentish rag, and much mixed with large and small stones. *Alfred O. Walker, F.L.S., Ulcombe Place, Maidstone.*

——The failure of Plums in this district is owing to the flowers having been few and weak. Late frost and continued easterly winds most affected Pears. Apples are plentiful in situations having a western aspect. Some Apple orchards facing east have unsatisfactory crops, though the trees flowered plentifully. *Geo. Fennell, Boarden, Hadlow Road, Tonbridge.*

Middlesex.—The severe frost in May, followed by east winds, greatly injured the tender foliage. Black Fly has been most troublesome. Our soil is very light, resting mostly on gravel, and requires much feeding and moisture-mulching in such a case is most important. *Geo. Withes, Syon House, Gardens, Brentford.*

——Apples in some instances have heavy crops, but they have suffered very much from drought. Peaches and Nectarines are excellent—this I attribute to the strength of the flowers through keeping the trees thinly trained, free of insects, and the trees were not allowed to carry too heavy a crop of fruit last year. We protected the trees heavily during the late spring frosts. Other fruits, with the exception of Pears, are very satisfactory. A few of the large blooms and buds of the Strawberry got nipped, but, notwithstanding, the crop of fruits was very satisfactory. Givon's Late Prolific should be cultivated in every garden. Our soil is of a sandy nature and not very deep, resting on gravel. Heavy top-dressings and mulchings are therefore very essential. *H. Markham, The Gardens, Wickham Park, Bromley.*

——Aphis has this year been worse than I have ever known it to be, and more difficult to eradicate. Our soil is of light loam, with gravel subsoil. *James Hudson, Osterley Park.*

Surrey.—Late spring frosts destroyed all the Apple, Pear, and Plum crops, which promised to be exceptionally good. The soil is very sandy and the subsoil also sand. *S. T. Wright, Royal Horticultural Society's Gardens, Wisley, Ripley.*

——Heavy mulching and strawing down very early preserved the moisture in a naturally dry soil, so that our Strawberry crop was exceptional. Plum trees here set a very heavy crop, but the majority fell after attaining the size of Peas. I consider the pollen was affected by the frosts and east winds experienced then, so that it could not properly perform its functions. The soil is chalky loam, on a chalky subsoil. *W. P. Bound, Gatton Park Gardens, Reigate.*

——The blossom on Plums was enormous, but the frost took it all. The same applies to Pears standing in the open, but the wall trees are bearing a half crop. *W. Wilks, Shirley Vicarage, Croydon.*

——The fruit crops were considerably affected, not only by the late frosts, but by the severe north-east winds, which prevailed for such a long period. The soil here is exceedingly light and sandy, resting on a subsoil of pure sand. *Wm. Howes, Cobham Park Gardens, Cobham.*

(To be continued.)

NURSERY NOTES.

THE OLD NURSERIES, CHESHUNT.

The words Paul and Roses are almost synonymous terms. We should not like to compute the number of beautiful Roses to which the prefix Paul's could be added, but this perhaps is not to be wondered at when one remembers that for about 100 years this famous house has been sending out, year after year, new varieties: some, perhaps, of more value than others, but collectively enough to furnish a Rose garden in themselves. The nurseries—for there are four of them—comprise an area of over 150 acres of ground, and herein are contained Roses in their thousands, of almost every conceivable variety and species. Fields of Roses, walls of Roses, banks and pergolas glowing with Roses, some trailing over banks, others sweeping their graceful wreaths of flowers from tall standard stems, the so-called Rose-garden with its severely geometrical design, miniature rock garden species, such as R. Wichuriana variegata, and another which is beautified by reason of its curious-coloured spines in contradiction to its near neighbour R. alpina, the thornless Rose; the so-called Scotch Roses, the China, Moss, Evergreen, and a host of other things that must bewilder even the most ardent Rosarian, and require a lifetime and the enthusiasm of such a man as George Paul himself to master. Nothing is perhaps more striking than the difference of habit and growth seen in the varieties; some form large trees, others are mere pigmies. One plant of Rosa rugosa rubra measured seven good paces through each way, seven yards of tangled growths bearing large, white, single flowers in countless numbers.

Let us first consider the newer Roses, for in this Rose mart is gathered all the newest and best from all sources. To commence with, Dean Hole has a fine pyramidal centre and perfect form, the colour being a mixture of salmon and carmine, a charming blend. The habit is vigorous and free-flowering. Mad. Theodore Roosevelt is of a pale-blush tint, resembling a beautiful light-coloured La France. The Dandy, a dainty little flower of dark crimson colour, was raised from Bardon Job. A pocket edition of its parent, it is just the thing for use as a button-hole flower. Cherry Ripe is a bright-coloured Hybrid-Tea Rose, with colour suggestive of its name—a cherry crimson. It possesses all the qualities needed in a bedding or a forcing Rose, and is recommended for market purposes. S. M. Rodocanachi is a great beauty of a lovely salmon-rose shade, and is becoming well known. David Harum is also already familiar to many of us, although it must still be considered a new variety. It is of American origin, and a not unworthy alien. The breed is Hybrid Tea, and it has size, form, and colour to commend it. The last-named attribute is rosy-pink. It is very free in blooming. George Laing Paul is perhaps the finest H.-T. yet raised, a very fragrant flower erect on long stalks, that display the blooms well above the vigorous foliage. The colour is deep carmine—almost crimson, and the flower is shapely. Florence Pemberton obtained the Gold Medal of the National Rose Society in 1902. A pink flower with plenty of petals, which overlap and reflex in perfect form, entitling it to be classed among exhibition varieties. Richmond takes its name from Richmond, the American city that supplies us with another luxury of the vegetable world. It was raised by Messrs. Hill of that place. Extreme floriferousness is one of its desirable characters; in addition it is fragrant, good in form, and is carried on tall, stiff stems. The colour is bright red. Etoile de France we must pass over, for, although good otherwise, it has the bad quality known as "burning." Hon. Ina Bingham has also a defect, for although its petals are of exquisite tint and very large, it is not of sufficient fulness to place it in the first ranks. Countess Annesley and Countess of Derby are both H.T.s of a salmon shade; the latter has a most perfectly shaped bud.

Nellie Johnstone is a grand new Tea Rose raised by Mr. Paul from Mme. Berkeley × Catherine Mermet. It more resembles the first-named progenitor, but is a little fuller, and of a pink shade. M. H. Walsh perpetuates the name of the famous American raiser, who has given us such fine things as Hiawatha and Lady Gay. It is a H.P. of rich velvety crimson colour, very large in size, and worthy a place among the best of new Roses. Tea Rambler is a decided novelty, and has resulted from the crossing of a Tea variety with a climbing Rose. It is one of the most beautiful Weeping Roses, with exceptionally strong growths, upon which it produces clusters of flowers in profusion. The colour is a deep coppery pink, which changes with age to a paler shade. Other good climbing or pillar kinds are the well-known Lady Gay, here quite fulfilling the good reputation it has; Una, a creamy white-flowered Rambling Briar; Trier, with dense clusters of creamy-white blooms, and The Lion, with flowers of a bright crimson shade. We may here remark in passing that of all these charming climbing Roses now so popular none was more beautiful than Wallflower, not new indeed, but with scarcely a peer among a galaxy of its kind. Mad. Paul Olivier may best be described as an improved Georges Nabonnand. Mons. Paul Ledé is a vigorous H.T. of a beautiful buff orange shade, with a suspicion of rose. The large J. B. Clark, the flower of last year's National Show, whose huge petals are maroon scarlet, was in its full beauty. Elisa Robichon is one of the Wichuriana Roses with petals of a soft yellow shade. Mad. J. Gravereaux is a climbing Tea Rose—a flower of good shape with yellow buff-coloured petals. A plenteous succession of flowers are produced, and it forms a capital variety for wall-covering. We will conclude our notice of the newer Roses with mention of Messrs. Paul's H.T. Lady Battersea. The flowers are light crimson with an orange-coloured base, and they are produced on tall, straight stalks, a valuable feature in a Rose for cut purposes.

Interesting Species.

As is to be expected in a nursery so largely devoted to Roses, there is an interesting collection of rare and peculiar species. The green Rose R. viridiflora cannot be termed a beauty, and few would care to afford it a place in their Rosary, but the thornless Rose R. alpina, being without thorns, is surely perfection indeed, and the double-flowering form is not to be despised from a decorative point of view. Then there is its antithesis R. sericea var. pteracantha, which is all thorns and bristles; indeed, the long, flattened decurrent spines are extremely handsome when in a young state, and with the sun on the opposite side of the beholder they glow a beautiful ruby-red.

The tiny Wichuriana variegata we have already mentioned: its foliage is slightly scented. Rosa rubifolia bears the handsomest foliage of all the genus Rosa, and should find a place in every collection for its ornamental wood and foliage alone. These are coloured red, and are admirable for mingling in vases of cut Roses, or indeed of any flowers. Another—R. lucida (syn. R. nitida)—has also ornamental leaves and wood. The leaves are shining and tinted red; R. lucida "Vivid" turns a lovely

colour in the autumn. R. setigera might easily be mistaken for a Raspberry, so much do the canes and leaves resemble that plant. Rosa rugosa is seen in many forms; some have been crossed with H.P.s to improve the flowers, but the old type is unsurpassable among Roses for its charming fruits in the autumn. R. Andersoni is one of the so-called perpetual flowering kinds; its single pink coloured flowers possess much merit. Rosa Kazanlik we should probably pass by, but the flower that furnishes Attar of Roses cannot be thus slighted; and, after all, one cannot judge of merit from appearances alone.

We see here also the old Cabbage Rose of our cottage gardens; the parti-coloured Rose—York and Lancaster; and Rosa mundi, which is more often sold as the York and Lancaster Rose, and which is probably the better of the two; the old Maiden's Blush, a great favourite still; the big leaved R. macrophylla, which has foliage more like an Acacia than a Rose; the Boursault Rose (R. alpina) Morletii, a vigorous climber; the strong growing R. Brunonis, with single white flowers and fine glaucous foliage; and a host of others.

The collection of ornamental leaved trees and shrubs in these nurseries is remarkably rich and varied; the 50,000 fruit trees, the Conifers, or the thirty plant-houses, all filled with general nursery stock, would each require a separate note to do them justice.

THE CRAVEN NURSERY, CLAPHAM, YORKSHIRE.

The Craven Nursery at Clapham, in Yorkshire, is now well known to lovers of Alpine flowers, especially to those who have an opportunity of seeing the exhibits made by the nursery at the Temple and other shows, where tastefully-arranged rockwork displays to the best advantage the flowers which are the speciality of the nursery—the best of the plants suited for the rock garden. Its situation is not particularly convenient for the traveller, lying, as the charming village of Clapham does, upwards of a mile from the station, which is itself on a cross-country line, the branch of the Midland from Settle to Carnforth, &c. For the growth of Alpine plants, however, the nursery is admirably adapted, being well up on the high ground close to Ingleborough, and in a district where many good British Alpine plants have their native habitats.

A recent sojourn in the district enabled me to pay a short visit to the nursery, which is under the care of Mr. George Redmond, an able cultivator, keenly interested in the plants he grows. The bulk of the Alpines are cultivated in pots for convenience of sale; but a rock garden, constructed with the natural stone of the district—limestone—serves to show what the plants will be when planted out in congenial surroundings, and is an object-lesson for those who wish to construct one of the same character.

Prominent among the plants in pots was Daphne rupestris or petræa, which was awarded an Award of Merit at the Temple Show, and has been favourably commented upon in the columns of the gardening Press. In consequence of this, the nursery has been inundated with orders for, and inquiries about, this Daphne, with the result that all the available stock has been disposed of. It may be mentioned here that Mr. Redmond grows it in peat, leaf-mould, and sand, with some grit, and that he keeps it root-bound, and in a position facing almost due north-west. A number of other Daphnes are also well-grown here, among them being D. arbuscula, a name which I cannot trace, and a plant probably new to cultivation.

One of the specialities of the Craven Nursery is the collection of Saxifrages, and one cannot fail to be delighted with the wide range of these, particularly of the Euaizoon or encrusted section, one of great beauty, and one which thrives well on the limestone formation. Mr. Reginald Farrer, the proprietor, is much interested in these, and many of the forms were collected by him in their native habitats. Some notes of the Saxifrages in the frames, taken as they came, are too numerous to be detailed; but perhaps I may mention a few among them. Some very fine forms of S. Burseriana are grown, in addition to the usual form, and S. B. major and grandiflora, and are named "Glory, 1 and 2." Another fine variety of S. Burseriana is called speciosa, and all three are superior forms of a most valuable early Saxifrage.

Of S. cochlearis the two forms, major and minor, deserve mention, as most people are only aware of the one. That named minor is a great beauty. A pink one, called S. Stribrnyi, is worth securing, and was new to me; while S. Aizoon rosea, not absolutely confined to this nursery, is worth noting, with Aizoon lutea, and such others as cuneata, Prostii, aretioides primulina (now scarce), Guthriciana variegata, Elizabethæ, Boydii, Boydii alba, Fosteri (the true form, the true ambigua, scardica, lilacina, Guildford seedling, australis, Frederici-Augusti, the form of porophylla called thessalica, and a host of others, including a hybrid raised here and called cravenensis, which is between S. hypnoides and S. Macnabiana.

Androsaces are well represented, among those noticed in passing through being A. Chumbyi, A. helvetica, A. pyrenaica, A. vitaliana, A. foliosa, A. strigillosa, A. lanuginosa, A. sarmentosa, and others. The Dianthi, also, are numerous, and I noted D. Simsii, D. frigidus, D. gelidus, D. Sternbergii, D. pruinosus (seedlings), D. cinnabarinus, D. superbus, D. superbus albus, D. alpinus, in several forms, D. aridus, D. neglectus, and a large number of others.

Primula species are also among the largest sections. P. farinosa grows in thousands on the mountainside close by, and some selected forms are grown, including farinosa alba; while among the many in the nursery one noted the names of P. Cottiæ, P. pedemontana, P. decorum, P. suaveolens, P. calycina, P. viscosa, P. Sturmiana, P. intermedia, P. jurabella, P. Wulfeniana, P. Reidi, and many more.

Among Campanulas I was delighted to see C. pulloides raised by Mr. T. H. Archer-Hind in such quantities, both in pots and in the rock garden. Its allied plants, such as C. G. F. Wilson and pseudo-Raineri, with the parents, C. pulla and C. turbinata, were also in large numbers, together with C. Allioni, C. Stansfieldi (another new hybrid), the true C. alpina (not the form of rotundifolia often known by that name, but the alpina of Linnæus), C. Scheuzeri, C. Scheuzeri alba, C. Zoysii, C. tyrolensis, C. petræa, C. collina, the form of rotundifolia called macrorhiza, C. Portenschlagiana major, C. garganica, C. hirsuta, C. turbinata, C. turbinata pallida, and, in fact, an almost complete set of dwarf Campanulas in cultivation.

Among other plants noted were Silene acaulis aurea, with pretty golden-coloured foliage; Gypsophila alpina rosea, a charming Alpine of trailing habit; the true Veronica Allioni; different forms of V. saxatilis, including alba; the new Silene pulchra, resembling Schafta, but with its petals of a different form; Ranunculus glacialis, R. parnassifolius, and R. rutæfolius, a plant not so often seen now, but a good Alpine.

Ramondias, in the several species and varieties now procurable, Haberlea rhodopensis and Jankæa Heldreichi are also grown, with several Oxytropises, including the purple O. montana, the pleasing purple Astragalus Vandesii; such dwarf Irises as I. melitta, I. lacustris, I. tomiophylla or tectorum, I. arenaria, and others; Erodiums cheilanthum and E. Sibthorpianum; Sedum corsicum and S. brevifolium var. Pottsii; a good stock of Mertensia maritima, doing well away from the sea and in bloom; M. primuloides; the quaint little Astrantia minor, now seldom seen in nurseries; the dwarf Doronicum Orphanidesii, apparently a better plant than D. Stiatellæ, which eventually becomes tall in our gardens; Geums, including G. reptans; a range of varieties of Geranium lancastriense, collected on Walney Isle, the original habitat of this crane's bill; with Sedums and Sempervivums, and many other plants in great numbers, and almost invariably looking in the best of health.

The rock garden is an admirably-constructed one of the native stone, which lends itself to such work. It combines picturesque effect with the provision of suitable pockets for the plants, and small rockwork pools are also provided for aquatics and semi-aquatics.

These notes have already run to greater length than I had intended, so that I can only refer to a few of the plants. Here were Helianthemums Jubilee and venustum or amabile fl. pl., the best of the double Sun Roses; a late purple Aubrietia called Craven Gem; Geranium Lowei, or anemonefolium; Calceolarias polyrhiza and plantaginea; Antirrhinum sempervivens; Mimulus Burnetti, with M. Brilliant and others; Castelleia minata (hardy here); Jankæa Heldreichi, which flowers here; Erodium pelargoniflorum; Dianthi in variety, and many other plants of herbaceous, suffruticose, or shrubby habit. The whole nursery is very interesting, and not the least pleasing feature is the cleanliness and order which prevails, and which is highly creditable to Mr. Redmond and his staff. *S. Arnott.*

CARNATION RAISING AT "THE WARREN," HAYES.

We may safely aver that no other amateur in this country has pursued the science and art of improving the Carnation and Picotee with so much success as Martin R. Smith, Esq., of Hayes, Kent, President of the National Carnation and Picotee Society. Nor has any trader or amateur distributed so many beautiful additions to these ever-favourite flowers. The raising of new varieties from seed is followed by Mr. Smith and his gardener, Mr. Blick, in no haphazard fashion, for every cross is carried out with definite aims; it may be to give an increase of size to the blooms of a variety; to improve or alter the markings, as in Picotee and Flake Carnations; to modify the number, size, and form of the petals; to raise flowers having the purest of ground colours—viz., white and yellow in Picotees; to improve the habit of growth, character of "grass," or strength of flower stalk in Carnations and Picotees of all sections, so that the flower can be looked at in the face. Every cross made is carefully recorded in a book, on reference to which every required particular about the parent plants may be readily obtained.

Mr. Smith is not easily satisfied in any of these points, and out of the many thousands of seedlings raised annually at "The Warren" by his gardener but few come up to his ideas of a good flower and are retained; even some of those which do so the first year of flowering, on further trial in the second or third year if found unsatisfactory are destroyed. Therefore, no seedling that is not a distinct advance in all points stands a chance of being perpetuated. On the occasion of a recent visit we were shown a field (!) of Carnations and Pico-

tees, consisting of seedlings of all the various sections, numbering 20,000 plants, a wondrous mass of bloom. These were flowering for the first time, from seed sown in warmth in 1905, and planted out in the field from the nurse beds in May and June the same year, the area filled by them being 1¼ acres. In another part of the field there were to be seen 17,000 plants of the present year's raising; therefore, about one acre in extent—nice stocky well-branched plants and standing four rows in a bed at 15 inches apart, with broad alleys between the beds. The land is a hungry, gravelly loam, overlying beds of gravel and standing in need of heavy manuring, whatever the crop may be that is raised on it. As a matter of fact, when it is dug in preparation for the Carnations a layer of cowdung, just as it comes from the sheds, is put on it out of reach of the roots of young plants, but which they will reach about the time it has begun to decay, so that, although the manuring is heavy, no ill results follow, and this mass of moisture-retaining material keeps the plants in vigorous health in the driest and warmest season. The vigour of the flowering plants was very remarkable, and the more so this present year of drought and heat. Vegetable crops in other portions of the same field, presumably under the same kind of treatment, showed good effects, likewise, of the cowdung. The work of selecting blooms from among this immense number of seedlings, all under numbers, is exceedingly onerous and incessant during the months of July and August, demanding an intimate knowledge of existing standard varieties. All selected seedlings are layered in some quantity, some of the layers being retained in pots for testing under glass; others, for out-of-door trials, are planted out in beds in the autumn. It is not every seedling that behaves well under glass or in the open, and this point has to be ascertained by actual experiment.

The Houses.

There are six large, span-roofed houses set apart for flowering the Carnations and Picotees, one of them being the flowering house for the artificially fertilised plants. In this one there were remarked only withered flowers and brown seed capsules, the work of pollination having been finished a week or two previously. Some of the plants were furnished with two, three, and four cardboard labels, on which the names of the varieties that furnished the pollen for the flowers were inscribed, one corner of the label being cut off so as to indicate the fact of pollination having been effected, this stage being indicated within twenty-four hours by the collapse of the flower. There must have been several thousands of these seed bearers awaiting the ripening stage, and the other houses were crammed with the flowering plants.

Carnation and Picotee Beds.

These are arranged in a triple line in a horse-shoe form at one corner of a very extensive lawn, slightly screened from the windows of the mansion, the beds being parallelograms in every case, measuring 3 feet square, and holding from six to nine plants. All the plants were growing with great vigour, and possessed abundance of strong shoots and leaves, and were quite free from any appearance of fungus disease. Noteeable blooms were of the following varieties: Maud Sullivan, a light rose-coloured self of moderate fullness; Floradora, old rose in tint, with a smooth edged petal; Lady Waterlow, cerise red in tint, with a smooth cupped petal and a good doer; Mirabelle, of very bright scarlet, fine out of doors (not exactly new); Grand Vizier, crimson-maroon, good form, and tint of great richness; Mrs. Leo Hunter, F.C., excellent indoors and outside, has extra strong flower stalks; Hesperus, yellow ground F., purple edge, tipped with crimson; Juno, yellow ground F.C., one of the best; Lady Linlithgow, colour old rose-pink, full, petal cupped; Mrs. W. Heriot, yellow ground Picotee, rose edged, one of the best of Mr. Smith's seedlings; Lady Audrey, F.C., yellow, excellent out of doors; Lady Hermione, a rose-pink self Carnation, a very pleasing flower of fine form; Cardinal, a brilliant scarlet self. Cavalier, a yellow ground fancy, has massive, large purple-maroon markings and edges; Merlin, a fancy edged and barred with purple, on a yellowish ground tint; Thais, F.C., with a primrose-yellow ground and slight markings of a crimson colour; Douce Davie, a yellow ground fancy; Sir Galahad, a very fine white self, habit neat; Darkie, C., self, a good upstanding bloom of a crimson colour, petals smooth and regular; Daffodil, yellow self, rather smaller than Cecilia, very nice; Rony Buchanan, yellow ground F. Carnation, markings purplish rose, a smooth cupped petal, and calyx firm and not liable to split. Hildegarde is one of the finest white Carnations, capital for the flower border, with flower stalks of moderate height only, and strong growth, also of moderate height. Agnes Sorel, crimson-maroon self, is good both indoors and outside. The variety King Solomon, a yellow ground fancy, which received an award of merit in 1904 from the R.H.S., was noted in several fine examples. Westward Ho, a yellow ground F., thickly barred with rose colour; Murillo, yellow ground F., crimson markings, are both good varieties.

Of yellow-ground Picotees Ace of Trumps scarlet edge; Annabelle, purple edged, and Lady Bird, yellow ground scarlet edge, are desirable varieties. Of new seedlings of Picotees mention may be made of Judith, Celito, each crimson edged; Nancy Lee, crimson edged, deep yellow ground; Sunbeam, Picotee, deep yellow, with a wire edge, a lovely flower and a circular petal; Ashantee, crimson self Carnation; Nautch Girl, a good form of a yellow-ground Picotee; Amy Charles, also of the same class and Asphodel, a Picotee with the true wire edge.

If the Carnations and Picotees make the most important portion of Mr. Smith's garden, other matters are not neglected. The vineries, fine, large, old-fashioned lean-to houses, with 20 feet long rafters and of great height, are furnished with vigorous, healthy Vines, on which heavy bunches of fruit were hanging in various stages of development, and without a single shanked berry, or the sign of the dreaded "spot" disease. Varieties noted were: Appley Towers, Lady Hutt, both of which give great satisfaction; Black Hamburgh, Muscat of Alexandria, fine, large bunches; and Gros Colmar. A change to the usual mode of growing Figs in vineries was noted, the trees, about 10 feet in height, being planted in the front of the vinery, the spurs on the Vines being removed to that height. These Fig trees bear excellent fruit abundantly. Heavy crops of Melons are grown in narrow span-pits, an alteration from the usual course being to plant a larger number of Melon plants, and take only two to three fruits from each. By this means fine large fruits are obtained, and there is no diminution in the number grown. In regard to Apples, Pears, Plums, Nectarines, and Peaches, the climate and soil being what they are, entire reliance is placed on trees grown in pots, from which excellent crops are obtained under glass and in wired enclosures in the open air. A growing attraction of the gardens is a large rockery that has been formed, and on which a good selection of choice Alpine and rock plants are making good progress. In the vicinity of the rockery an extensive collection of abnormal forms of hardy Ferns has been established, which will be added to as occasion arises.

VEGETABLES.

POTATO TRIALS AT MARKS TEY.

An exhibition and inspection of trials of early Potatos grown at Marks Tey, took place on Wednesday, August 1. The trials were organised by Messrs. Dobbie & Co., in conjunction with Mr Thomas A. Scarlett, of Edinburgh.

The two firms jointly offered £55 in cash prizes, as well as some medals, and there were over 400 entries. It is the first time on record that an early Potato show has been held, and the success must be gratifying to the promoters. The exhibits came from all districts of the United Kingdom and Ireland, and some from the Isle of Man.

The judges were Mr. Edwin Beckett, of Elstree, and Mr. Charles Foster, chief of the Horticultural Department of University College, Reading.

The show was held in magnificent weather. The inspection of seed trials was very interesting (a detailed table of which is given below), and was good testimony to the superiority of farmyard manure over artificial manures.

The exhibits were displayed in a spacious marquee, and, considering the exceptionally dry season, which is most unfavonrable to an early show, were of such excellence as to exceed even the most sanguine hopes. There were 411 entries and 190 exhibitors.

The winner of the gold medal, for the best ratio of increase from the "Midlothian Early" Potato, obtained a yield of no fewer than 80¼ lbs. from 1 lb. of seed Potatos. The winner of the silver medal made a good second with a yield of 72 lbs. from the same quantity of seed.

It was found to be impossible to raise the trial rows on the show day, so Mr. Alexander Dean, Kingston-on-Thames, visited Marks Tey on Friday, the 27th ult., and superintended the raising and weighing of the varieties on trial.

On the 12th April, 120 sets of each variety (Scotch seed) were planted, 60 sets in ground manured with farmyard manure at the rate of about 30 tons per acre, and 60 sets in land manured with a good artificial manure at the rate of 8 cwt. per acre. All other conditions were equal.

Subjoined is the result.

FOREIGN CORRESPONDENCE.

RUBUS LUCRETIA.

In the issue of the *Gardeners' Chronicle* for July 14, p. 25, an illustrated reference is made to Rubus Lucretia, "obtained from Holland some few years since, but without any history." Is not this the familiar Lucretia Dewberry of American nurserymen? If so it is a form of Rubus villosus Ait. (formerly called R. canadensis) to which Prof. Bailey has added the varietal designation of raribaccus. It is a native of West Virginia, with a vigorous, thorny procumbent habit. Fruit-growers in the Northern States usually set the plants 6 × 6 feet. At the beginning of winter they are well mulched with

manure. In spring five or six of the strongest shoots are tied up to a stake in each hill, the rest being cut off. In the fall they are allowed to trail, as the canes are killed in the winter if exposed. In some places they are trained to wires like Grape vines. The Dewberry is a useful commercial fruit, ripening about two weeks before Blackberries. It should prove very desirable in Great Britain, as our Rubus fruits seem to succeed well with you. Mayes is another variety, from Texas, still earlier than Lucretia, but not yet thoroughly tested in the North. My impression is that it is a little less hardy here. *Emily Taplin Royle, Maywood, New Jersey.*

The Week's Work.

THE ORCHID HOUSES.

By W. H. White, Orchid Grower to Sir Trevor Lawrence Bart., Burford, Surrey.

Cypripediums.—The majority of the dwarf-growing species as *C. niveum*, *C. concolor*, *C. bellatulum*, and *C. Godefroyæ*, also many of their hybrids, have passed the flowering stage, and some of them will need repotting; but this operation should not be done oftener than is absolutely necessary, because the roots are so very brittle in nature that some of them are sure to be injured during the process, and injury to the roots is more harmful to these plants than to others of the same genus. The pot in which a well-established plant is growing should be broken around the top, and the pieces carefully removed down to the drainage, leaving this untouched if it is permeated with living roots. Place the whole mass into a larger pot, and fill up to the level of the old drainage with pieces of broken brick or crocks. Make the compost which is put over this moderately firm, and for the species let the compost consist of tough, fibrous loam, freely intermixed with small crocks and some coarse silver sand. The hybrids require a little peat in addition to the above materials. When the operation is completed, prick in a few heads of living sphagnum-moss over the surface. The level of the compost should be left just below the rim. Keep the roots well supplied with water at all times, especially when the plants are in full growth. After repeated trials, I find that these plants succeed best if suspended in a light position near the roof of the Cattleya house, where air can circulate freely around them, but where they will not be subjected to strong, direct sunshine.

Gomesa laxiflora.—This charming "botanical" species is now in flower. Each of its arching flower spikes, of which there are about 50, produces between 30 and 40 flowers, the sepals and petals being of a yellowish shade, with a white lip. It is a very floriferous species, easy to cultivate, and lasts a long time in bloom. The pseudo-bulbs are produced one after another in an upright direction, and in course of time the upper part of the plant gets the better of the lower, and lives away on its own account; but under artificial cultivation, if left undisturbed, the top growths become ultimately weaker, and do not bloom satisfactorily. When—or before—deterioration commences, either at the base of the stems or at the top, turn the plant out of the pot and cut the stems off up to the healthy portion, taking care to leave the piece of footstalk below the pseudo-bulbs as long as possible, so that this may be inserted into the new compost with the pseudo-bulb resting on the surface. The pot or pan should be made about half full of drainage. Fill up the pot with a compost of peat and sphagnum-moss, and, getting some neat stakes, begin in the centre and tie the strongest pieces there, and so on until the pot is full. Stand the specimen in a light position in a cool part of the intermediate house, and whilst growth is being made syringe it over lightly twice or thrice each day.

Grobya galatea, also now in bloom, is another species highly appreciatad. The flowers are densely borne on short semi-pendulous spikes, arising from the base of the pseudo-bulbs, and rest just over the rim of the pot. The plant grows freely in a cool part of the intermediate house; it requires very careful watering at all times, and the compost should never be made very wet. While the plant is at rest keep the soil rather on the dry side.

PLANTS UNDER GLASS.

By B. Cromwell, Gardener to T. Sutton Timmis, Esq., Cleveley, Allerton, Liverpool.

Freesias.—These Cape bulbs can hardly be over-rated where choice, fragrant flowers are appreciated. The Cape-grown bulbs are now to hand, and if potted forthwith may be had in flower from Christmas onwards, and just at the time when Chrysanthemums are on the wane the Freesias will be of great value for dinner-table and vase decoration. The bulbs should be potted in a compost of good, fibrous loam, well-rotted manure from a spent hot-bed, charcoal siftings, and a free addition of sand. If the compost is in a suitable condition of moisture when potting, one good soaking of water will suffice until the young growths appear. Many failures in growing Freesias are brought about by the too frequent application of water to the bulbs before they have commenced to grow, and many of the bulbs decay in consequence. Copious supplies may be given when the pots have become filled with roots, and then the application of liquid manure will be beneficial. The pots should be stood on a well-drained base of coal ashes, in a cold frame, and, until growth has commenced, should be shaded from the drying influences of the sun, admitting air and light to them gradually. Avoid having the atmosphere too hot at any time. A temperature of from 50° to 60° will be found sufficient for their requirements. Under this treatment the Freesias will grow strongly. They will need neat little stakes, such as may be obtained from the prunings of Privet, after being dried on the top of the boiler. Home-grown bulbs should be potted up at intervals for a succession. Pots 5 inches or 6 inches in diameter are most useful for Freesias, and about one dozen bulbs may be placed in each.

Poinsettias.—Plants which are making vigorous growth, and are already furnished with plenty of roots, should be afforded more ventilation, and the shading may be dispensed with, except for a short time during the hottest part of the day. Encourage growth by syringing the plants freely each morning and afternoon, leaving a small amount of ventilation open throughout the night. Any late-rooted plants of Poinsettias not yet finally potted should receive early attention. Success will be attained by securing firm, short-jointed, and thoroughly-ripened wood from which alone large bright scarlet bracts, of good form and size, may be expected, contrasting strongly with the features of every other plant with which it can be associated.

Schizanthus retusus.—Seeds of this plant may now be sown in pans or boxes, and later sowings made in the middle of September, from which a profusion of flowers may be had in the early spring months. A greenhouse pot is the best place to winter the plants after they have been potted into 6-inch pots, putting seven or nine plants in each pot. In the cut state the flowers will be found useful for filling glasses. The soil for Schizanthus should be of a rich and light nature.

FRUITS UNDER GLASS.

By T. W. Birkinshaw, Gardener to Lt.-Col. Sir Chas. Hamilton, Bart., Hatley Park, Bedfordshire.

Vines.—Plants that are in need of repotting should be moved into their final pots as soon as possible. Keep those that have already been repotted in a somewhat close atmosphere, and water them with extra care till the roots have taken hold of the new compost. Spray them overhead at closing time, but do not allow any water to remain in the axils of the leaves. The hotbed should be kept for successional plants and others at a temperature of from 80° to 85°. If sufficient stock has not been secured, more suckers should be at once put into 7-inch pots, which should be well drained, using a compost of good fibrous loam, charcoal, sand, and bone-meal, the ingredients being in a moist condition at the time of using in order that no water need be afforded. Plunge the pots into a hotbed until the plants have formed new roots. Plants that are required for fruiting early next season should be allowed more space and somewhat cooler conditions.

Apple and Pear Trees having their roots confined to pots should be given abundance of water, carefully examining each plant two or three times each day. If the pots can be partially plunged, watering will not be needed so often. At this date the fruits will develop quickly if the trees can be put outside in a position sheltered from winds. Pinch the shoots whenever this is necessary, so that the formation of fruit-buds may be encouraged.

Cherry Trees growing in permanent borders will have been cleared of their fruit, therefore the ventilators may be left wide open by day and night. Continue to syringe the foliage every day, and give attention to the watering of the borders so that the fruit-bearing spurs for another season may be strengthened. Afford abundance of air to late varieties growing in pots; syringe the trees daily, and afford water to the roots whenever necessary. When the fruits show signs of ripening, syringing must be discontinued. All early varieties that have finished fruiting should be removed to a position out of doors, plunging the pots in ashes or soil.

THE KITCHEN GARDEN.

By J. Gibson, Gardener to His Grace the Duke of Portland, Welbeck Abbey, Notts.

Capsicums and Chilies growing in pots in frames should be watered liberally with liquid manure from time to time. Admit plenty of air at all times during the present month, after which the plants may be removed into a greenhouse for the fruits to ripen.

Spinach.—Although it is rather early to sow Spinach for obtaining plants to stand through the winter, it is, nevertheless, an excellent plan to sow a batch well in advance of the main crop to provide for emergencies. There should be plenty of available space in large gardens from now onwards, owing to the crops of Peas, Beans, Potatos, etc., passing over. Thoroughly break up the ground before sowing the seeds, selecting an open space in the garden, for this crop usually succeeds better in such a position than on borders, where the plants become more tender and are consequently more readily injured by changes in the weather. When sowing the seed it is a good plan to sow soot broadcast, using soot that has been stored for some time. This has the effect of helping to prevent attacks from insects that are sometimes troublesome to the root stems.

Celeriac are most useful for planting at the present time rather closely together, as they form an excellent catch crop. There is not a great variety to choose from, and the old Hardy Green sort still holds its own.

Storing Onions.—The dry and hot weather is in many instances prematurely ripening this crop. More often than not Onions are left too long on the growing quarters before being pulled. An Onion with the neck dying down is far more likely to keep if pulled at once than if left longer, when an effort might be made within the bulb to grow again. This is the point where bad keeping commences, and if after this the bulbs are put into a close store or room not sufficiently ventilated, the failure is completed. It is without doubt best to pull the bulbs up just when the necks are limp, and dry them off in the sun, or if growing in a very late locality, they may be given the advantage of a stage in a frame on the fruit houses, where they will be free from heavy night dews or rains. Well-ripened Onions will take no harm from frosts after being stored, providing they have been well ripened and have plenty of air. A shed open at the side is a most suitable place for storage. Large specimen bulbs for exhibition purposes require special care. They should be raised with a fork, otherwise they are apt to split at the base.

Main Crop of Celery.—This crop will require regular attention in the way of having the side growths trimmed off, and in earthing-up the plants from time to time. Celery requires much moisture and feeding, but unless very large heads are wanted the plants should get sufficient from the manure they were planted in. It is much better at this season to partially earth-up the plants at two or several operations than to attempt to do the whole at once, when the centre of the plants would be liable to become burned, and have little chance of growing straight and becoming solid. Sowings of soot and lime are excellent to incorporate with the soil used for earthing-up, as they help to destroy injurious pests, such as slugs &c. About this time the latest brood of Celery fly usually makes its appearance, and it will be well to syringe the plants with paraffin emulsion every week.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the **PUBLISHER, 41, Wellington Street, Covent Garden, W.C.**

Letters for Publication, *as well as specimens and plants for naming, should be addressed to the* **EDITOR, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Special Notice to Correspondents.—*The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.*

Illustrations.—*The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c., but he cannot be responsible for loss or injury.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.*

Local News.—*Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

APPOINTMENTS FOR THE ENSUING WEEK.

SATURDAY,	Aug. 11	Dutch Gard. Soc. meet.
TUESDAY,	Aug. 14	Roy. Hort. Soc. Comm. meet. Exmouth Hort. Sh. (2 days).
WEDNESDAY,	Aug. 15	Taunton Deane Hort. Sh. (2 days) Wilts Hort. Sh. at Salisbury.
THURSDAY,	Aug. 16	Manchester & North of England Orchid Soc. meet. Merthyr Fl. Sh ; U-k Fl. Sh.
SATURDAY,	Aug. 18	Sheffield Hort. Sh. German Gardeners' Soc. meet.

AVERAGE TEMPERATURE for the ensuing week, deduced from observations of Forty-three Years at Chiswick—62·5°.

ACTUAL TEMPERATURES:—

LONDON.—*Wednesday, August* 8 (6 P.M.): Max. 82°, Min. 57°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—*Thursday, August* 9 (10, A.M.): Bar., 30·1, Temp., 70°; *Weather*—Fine.

PROVINCES.—*Wednesday, August* 8 (6 P.M.): Max. 77° Guildford, Min. 54 N.E. Scotland.

SALES.

FRIDAY—

Imported and Established Orchids, at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 12.45.

The Hybridisation Conference.

In the present issue we are enabled to publish a summary account of the proceedings of the Hybridisation Conference, from the time that we went to press last week, to its conclusion on Friday, the 3rd inst. If the papers read in the first half of the Conference were, appropriately enough, of an academic character, those in the latter portion of the meeting were distinctly of practical importance. The general tendency of the "practical" man is to enquire "What is the use of all this? How does it, or how can it, help me in my daily work?" This is quite natural and easily intelligible, but the more completely the practitioner is enabled to grasp the significance of the somewhat recondite matters brought forward at this Conference the more clearly will he appreciate the exceeding value of these experiments and these researches to his practical work in the future, if not in the immediate present. M. Noel Bernard's paper on the relation of certain fungi to the growth of Orchids is a case in point. The presence of fungal threads on the roots of certain seedling trees has long been noted, but at first no one dreamed that it was possible that such association could be anything but mischievous. We know better now, and see that the fungus supplies to the seedling material which the seedling could not obtain for itself. M. Bernard now teaches us the same lesson with regard to Orchids. We commend his paper to all those engaged in the risky process of raising Orchid seedlings. If we refer to the paper of Sir Daniel Morris we shall see how matters that might be thought of purely botanical interest are fraught with the most important practical consequences. It was a mere botanical curiosity when it was discovered that the Sugar Cane occasionally produced seedlings, but now from that little germ has arisen the power of increasing the output of sugar and of enhancing the power of resistance against disease. Mr. Biffen's paper on the breeding of Wheat is even more remarkable, and the results obtained are of the highest possible potential value.

It is of no use wringing our hands and lamenting that our cousins across the Atlantic, and our more distant relatives across the Channel, are sharper than we in perceiving the significance of all these matters, and are already turning them to advantage, as was revealed at the Conference. What we have to do is to follow in the same track. We have as much brain-power in the old country as they have in the new or in Germany. Our leaders are every bit as intelligent and resourceful, but the masses, and even our legislators, are deplorably inappreciative and careless. Such meetings as have been held this week must have their influence in inducing us to comply with the saying of the Prince of Wales on his return from a Colonial trip—"Wake up, England!" In fact, the Conference has been a great success, and the thanks and congratulations of the community are due to the R.H.S. for their efforts in this matter. We have always thought that the various conferences held at Chiswick, and even at South Kensington, were of much more importance than the endless series of exhibitions, the chief value of which is commercial. Commercial interests are of very high importance, but they can look after themselves. The kind of information elicited from these conferences could not be extracted by commercial methods alone: they require the scientific method and the trained intelligence, in addition to the business instinct. We have already congratulated the society in this matter, but we should not be doing our duty if we failed to recognise the ability, the tact, resource, and courtesy which characterised Mr. Bateson in the prolonged and arduous duties imposed upon him as chairman.

In our last issue we were enabled to give portraits of some of the leading members of the Conference and a view of Burford, where the members were hospitably entertained by Sir Trevor and Lady Lawrence. This week we give some illustrations of one of the gardens at Gunnersbury, where Mr. Leopold de Rothschild offered luncheon to the members as they passed on their way from the Natural History Museum to Kew, and hope in our next issue to publish further illustrations from the other garden at Gunnersbury, that under the care of Mr. George Reynolds. What impression our foreign guests could have obtained from their hasty visit to these establishments we can hardly conceive. At any rate, we meant well.

OUR SUPPLEMENTARY ILLUSTRATION.—Among the eight new varieties of Sweet Peas which received recognition by the National Sweet Pea Society at the Exhibition on July 5th, no fewer than half were presented by Mr. C. W. BREADMORE, Winchester, including the three sketched by Mr. WORTHINGTON G. SMITH, and reproduced in our Supplementary Illustration. Audrey Crier was considered by a committee of the National Society the finest new variety of the year, and accordingly it received the Society's Silver Medal, offered for the flower of highest merit among new kinds. A full description of each will be found on p. 36, to which we must refer our readers. Etta Dyke will be especially welcomed, as it gives us a white flower with the form and grace of the Countess Spencer type. On p. 84 we gave an illustration of another excellent new variety, Rosy Morn. This was shown by Messrs. CANNELL & SONS before the Floral Committee of the Royal Horticultural Society at the meeting held on July 17th, when it was granted an Award of Merit. Probably no flower has a greater tendency to sport than has the Sweet Pea, and doubtless it is owing to this fact that we have become possessed in so short a time of such diversity of form and colour in this now popular flower; but we must not lose sight of the fact that all sports are not necessarily advances, therefore to ensure a variety flowering true it should be thoroughly fixed. We mention this because when inspecting a trial of these flowers recently many of the rows of newer varieties showed so many sports that it was difficult to recognise the true variety. In independent trials, for instance, the variety Audrey Crier was found to be extremely variable.

ROYAL HORTICULTURAL SOCIETY.—The next meeting of the Committees will be held on Tuesday next, August 14th, in the Society's Hall, Vincent Square. A lecture on "Artizans' Gardens in Large Towns" will be given by Mr. F. COCK at three o'clock.

BOTANICAL MAGAZINE.—The August number contains coloured figures and descriptions of the following plants:—

RHODOSTACHYS PITCAIRNIIFOLIA (*Bentham*), tab. 8,087.—A spiny-leaved Bromeliad of tufted habit whose central head of blue flowers is encircled by a ring of scarlet floral leaves. It is a native of Chile, and flowered at Tredarvah, Cornwall, last November, having previously flowered at Kew. Mr. DORRIEN SMITH notes that the plants flower annually in the open air at Tresco. The plant is here described by Mr. C. H. WRIGHT.

BULBOPHYLLUM ERICSSONI (*Kränzlin*), tab. 8,083. —See *Gardeners' Chronicle* 1897, i., 61, fig. 16.

BORONIA FASTIGIATA (*Bartling*), tab. 8,089.—A pretty greenhouse shrub from West Australia, with small, ovate, dotted leaves and clusters of small pink flowers. The four ovaries are free, but the styles are united for the greater part of their length. Mr. SPRAGUE contributes the description.

CODONOPSIS TANGSHEN (*Oliver*), tab. 8,090.—A curious climbing Campanulaceous plant, with stalked, ovate, lanceolate dentate leaves and large yellowish bell-shaped flowers on long stalks. The root is used for medicinal purposes by the Chinese, under the name of Tang Shen. It was introduced to the Veitchian nurseries by Mr. E. H. WILSON. It is described by Mr. SKAN, Kew.

HEDYSARUM MULTIJUGUM VAR. APICULATA, tab. 8,091.—Mr. SPRAGUE here describes a form differing from the type in the smaller number of its leaves, which are apiculate and glabrous. Its long pinnate leaves and spikes of rosy lilac, pea-shaped flowers render it very attractive. Kew

FLOWERS IN SEASON.—From LADY ACLAND, Killerton, come gorgeous flowers of Mutisia decurrens. Apart from the splendour of the flowers, the Mutisias are remarkable among Composites for their climbing habit and tendril bearing leaves as

well as for the structural conformation of the flowers. A small plant put out at Killerton, Devon, at the foot of a west wall three years ago is now, we are told by the gardener, Mr. Coutts, some 12 feet high, and is at present smothered in flower; just now there are over 200 flowers on it, and it is a gorgeous bit of colour when they are all expanded. This plant, which is a native of the Chilian Andes, was collected by Pearce for Veitch & Sons, of Exeter and Chelsea, and first flowered in 1862. It is a plant that has generally been considered difficult to do, but given the right position it seems to be very little trouble.

From Messrs. Jas. Veitch & Sons, Chelsea, we receive specimens of two stately plants—the one is Senecio Wilsonianus, of Hemsley, described in our columns on September 16, 1905, p. 212, the other is Buddleia variabilis var. magnifica, *Gardeners' Chronicle*, 1905, xxxvii., p. 115, 157. Both are described in the noble "Hortus Veitchii." Senecio Wilsonianus is a stately species with broad, reniform, finely-toothed leaves on long stalks, which are covered with down, while the leaf-blade itself is quite smooth. The yellow flower-heads are very numerous, arranged in tall, erect spike-like racemes 5-6 feet high, resembling those of an Eremurus. It was introduced from Western China by E. H. Wilson. Buddleia variabilis var. magnifica was introduced from Hupeh by Wilson. "It differs from the brilliant Veitchiana which it equals in size of flower-spike in profusion of bloom, in a more constricted thyrsus, and in having flowers of a deeper, richer shade of violet purple."

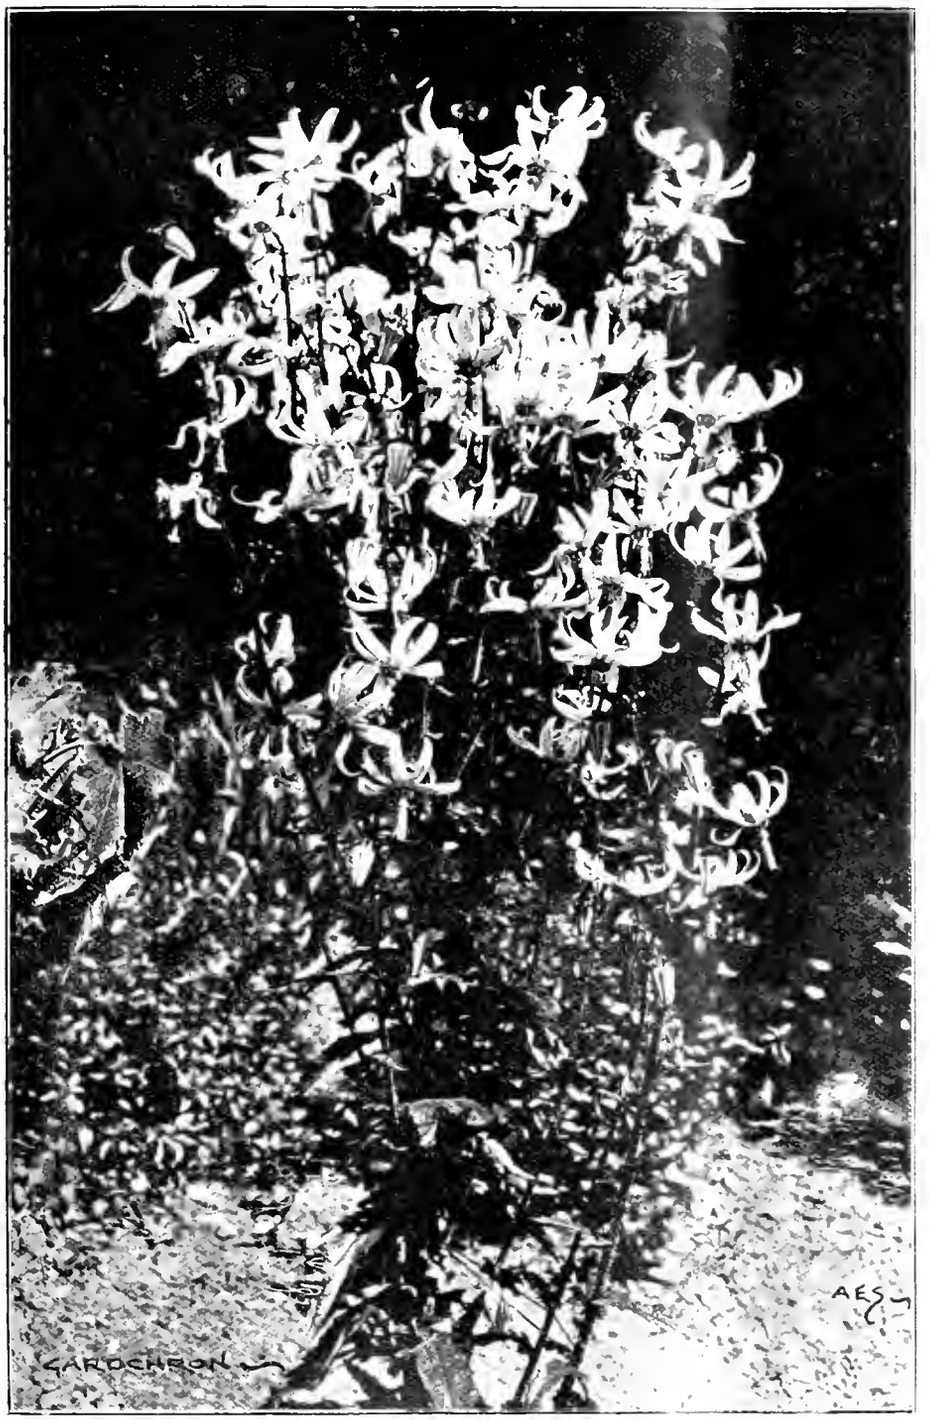

Fig. 43.—Michauxia campanuloides: flowers white.
(For text see page 112.)

Kew Bulletin. The last number of this periodical (No. 5, 1906) contains an interesting and elaborate article on Burmese lacquer, the produce of Melanorhœa usitata, a Burmese tree, and on the manufacture of the lacquer ware. The article is contributed by Sir George Watt, who says, in conclusion, that it is a varnish of great merit and immense possibilities that at present practically takes no part in the arts and industries of Europe and America. Mr. Hemsley describes several of the novelties from Western China, collected for Messrs. James Veitch & Sons by Mr. E. H. Wilson, and leads us to hope that eventually a larger and more general contribution may appear. Some of the descriptions are signed by Mr. Hemsley and Mr. Wilson jointly, whilst the latter author contributes some interesting notes which whet our appetite for more of like nature. Numerous new species are also described by various members of the staff, from tropical Africa, and are also welcome. J. M. H. contributes a note on "Miraculous Fruits" of West Africa, which have the property "of changing the flavour of the most acid substance into a delicious sweetness." The tree in question is Sideroxylon dulcificum, a member of the Sapotaceous family; the fruit of which resembles a small plum with the seed invested in a thin, soft pulp, wherein lies the peculiar sweetening property. Thaumatococcus Danielli, a Scitamineous plant from the Soudan, has similar properties. Picea Brewerana (see *Gard. Chron.*, April 17, 1886, p. 497) is the subject of a note, the Kew plant being, it is believed, the only one alive in Europe. It is one of the flat-leaved spruces with pendulous branches. A note of great interest to Orchidists relates to the collection of drawings made by the late Mr. John Day at Tottenham. They are about 3,000 in number, and specially valuable as comprising many of the types described by Reichenbach, now preserved at Vienna, where, according to the terms of the Professor's will, they will not be available until 1914. An interesting biographical note on Mr. Day is contributed by Mr. Hemsley. Another biographical note of great value is that by Sir Joseph Hooker on his life-long friend and associate the late Mr. Bentham, in connection with the recently published biography by Mr. B. Daydon Jackson. We have only indicated a few of the contents of this particularly interesting number.

Mr. Wythes.—We greatly regret to hear that this eminent and widely known gardener is about to relinquish his position at Syon House, mainly on the score of ill-health. Mr. Wythes will leave Syon at the end of September, and take up his residence in the vicinity of Folkestone.

National Potato Society. We are informed that the annual inspection of the trials of seedlings and novelties now being conducted at Burgoyne's Farm, Impington, near Cambridge (under the supervision of Prof. T. H. Middleton, of the Department of Agriculture, Cambridge University), will take place to-day, August 11, at 2.30. Histon, on the Great Eastern Railway, is the nearest station to the farm. It is hoped that a good number of members will avail themselves of the opportunity to inspect the trials, which are of a very interesting character.

The Azores Islands Lily.—The culture of Lilium longiflorum is advancing in these islands. The plants are reputed to be free from disease, and are remarkably sturdy and vigorous. The *Weekly Florist's Record* says that the bulbs are slow to grow, but that they endure cold storage as well as the ordinary kinds.

Icones Selectæ. The publication of this valuable work is being satisfactorily carried on. Vol. V., fascicle seven, contains the descriptions and plates of Drimys aromatica, Spiraea hexagemmis, Rhipsalis trigona, Atriplex coriacea, and Passerina filiformis. Fascicle eight deals with Eutaxia myrtifolia, Genista Nyassana, Dicliptera Niederleiniana, Vitex Negundo, and Babiana flabellifolia.

DR. KARL BOLLE.—Well known in botanical and literary circles, this gentleman celebrated recently his 60 years jubilee as a medical practitioner, his age at the time being 84 years. He is best known in the horticultural world as a Dendrologist. On his property, the Isle of Scharfenberg, near Tegal, he possesses a valuable, scientifically arranged collection of trees and shrubs, which he is willing to show to anyone interested in these plants on previous application being made to him. About 20 years ago, when the formation of the Berlin Botanical Gardens was being taken into consideration, it was proposed to purchase Scharfenberg on account of the valuable collection there, but ultimately Dahlem was chosen as the site of the new garden.

A NEW BLACKBERRY.—Messrs. ROBERT VEITCH & SON, the Royal Nurseries, Exeter, have sent some fruits of their new Blackberry, Rubus Lucretia, which was figured in a recent issue. The berries are large, juicy, and of good colour and substance, and ripen early (see also p. 108).

GARDEN OUTINGS.—The Royal Horticultural Society did its best to provide entertainment for foreign guests last week, but they were outdone in this particular by the managers of one of the American gatherings lately. Among the entertainments provided was one in which a number of competitors had their hands tied behind them. A number of large Water Melons, cut in halves, was then provided, and the competitors set to devour as much of the juicy fruit as their crippled condition would permit. Judging from the smiles on the faces of the bystanders the onlookers had the best of the fun.

BEECH TREES AND LIGHTNING.—An inquest was held at Hemingfield, near Barnsley, on two miners, who were struck dead by lightning whilst sheltering with others under a large Beech tree in Wombwell Wood, on the morning of July 31. The Coroner, in summing up, said that the sad event raised a rather interesting question. He had for years read that there was no record of a Beech tree being struck by lightning, and he had also read of people in some countries placing Beech trees around their houses for the purpose of protection from lightning. In the course of his experience he had seen and heard of very many trees that had been struck by lightning, and 99 out of every 100 were Oak. He had never heard of a Beech tree having been struck before. He went purposely to look at the tree to make sure that it was a Beech, and he saw no mark of an electric flash in any shape or form. In striking an Oak tree, he had known the lightning send sparks as far as 200 yards, but in this case it never injured the tree. This was a most singular circumstance, for he believed it was an accepted fact that a Beech tree has never been struck by lightning. He should include in his official verdict a note that the men were sheltering under a Beech tree when they met their deaths.

THE LATE DUKE OF RUTLAND.—Horticulture loses one of its most liberal patrons in the recent death of the aged Duke, Master of Belvoir, near Grantham. He maintained the gardens around the Castle well, and was always willing for anyone to go and see them, and allowing visitors to roam about at their pleasure. Spring gardening, as our readers are aware, was one of the principal features at Belvoir. The Duke was a model landlord and employer, always interested in the welfare of those connected with his large estates, and taking especial notice of the cottage gardens and allotments, which are very good in this district. The present gardener, Mr. W. H. DIVERS, has frequently spoken to us of his late master in terms of high appreciation.

Publications Received.—*Mushrooms and how to grow them*, by J. F. Barter (Napier Road, Wembley, Middlesex). *Fungoid Pests of Cultivated Plants*, by Dr. M. C. Cooke (R.H.S., Vincent Square), a valuable reprint, to which we must refer at length when our columns are less crowded.—*Agricultural Returns relating to acreage and produce of Crops and number of Live Stock in Great Britain for 1905* (Wyman & Sons). A very valuable synopsis.—*Plantes Bulbeuses, etc.*, par Raphael de Noter. Paris. (Charles Amat).—*The Book of Market Gardening*, by R. Lewis Castle (John Lane).—*A First Course in Practical Botany*, by G. F. Scott Elliott (Blackie & Son).—*Insect Pests of the Farm and Garden*, by F. Martin Duncan (Swan Sonnenschein).—*Catalogue of the Plants of Kumaon* (Lovell, Reeve & Co.).—*The Yachting World*, June.—*Report of the Botanical and Forestry Department, Hong Kong*, for the year 1905. In the Botanic Gardens the year was free from serious damage by typhoons. Libocedrus macrolepis flowered in the new garden for the first time. In April an expedition was sent by the Government to investigate the botany of the province of Tokien, and brought back much of interest.—*Jamaica Bulletin of Agriculture*. June. Contents: Silkworms from Jamaica, Leather, Coffee, Tea, Island Cotton Seed, and application of Paris Green to cotton.—*Queensland Agricultural Journal*. June. Contents: Manures, Australian tobacco crop, tropical industries, contributions to the Flora of Queensland, F. M. Bailey, &c.—*Agricultural Gazette of New South Wales*. June. Contains papers relating to crops, forestry, and stock.—*Report of the Connecticut Agricultural Station for 1905*. Details the critical studies made by Dr. Clinton of the Peach Scab and other fungoid diseases, of the investigation into vegetable proteids by Dr. Osborne, and much similar work of scientific and economic value undertaken by various members of the staff.—*The Business Man's Magazine*. July. (English Edition).—*Some Facts about the Weather*, by Wm. Marriott, F.R.Met.Soc., Assistant Secretary. A popular meteorological hand-book, telling how climatic variations are recorded, and helping observers to understand indications for themselves.—*Sugar Cane Experiments in the Leeward Islands*. Reports from Antigua and St. Kitts for 1904-5. Part II. Manurial Experiments. Details the results of five years' work, which it is hoped will tend to prevent waste and direct effort into proper channels.—*Scheme of Agricultural Education in connection with the Lancashire Education Committee.*—Dr. H. L. Snape, Director of Education. Useful work is carried on at the County Council Farm, Hutton, near Preston, and instruction is given in all branches of agriculture, in horticulture, and more general subjects. Men and women teachers and pupils are admitted.

FIG. 44.—VIEW IN A DONEGAL GARDEN.
(For text see page 113.)

MICHAUXIA CAMPANULOIDES.

THIS, though rarely met with in gardens, is one of the most beautiful and stately of border biennials, and always evokes admiration when seen in any quantity and at its best. It was introduced into this country in 1789, and was first flowered in a nursery in Kensington in July of 1792, from which specimen, grown in a pot, it was figured in the *Botanical Magazine*, 7, tab. 219. It is a very striking and remarkable plant, and it is a matter of surprise that it is so little grown. The stems are numerous and branching, and the plant, when well-grown, forms a pyramid some 5 feet or 6 feet in height. The blossoms, which bear a certain resemblance

to those of a Passion Flower, are large and consist of eight, long, white reflexed petals, and are borne in quantity on the branching shoots, so that, when in full flower a fine plant attracts the attention from afar as a pyramid of white. The height of 5 feet to 6 feet mentioned above is often exceeded, an altitude of 8 feet or even 10 feet being sometimes attained, but in such cases the side branches are generally few and weak, and the plant does not present the pyramid of bloom that renders it such a conspicuous object in the border. Occasionally plants do not die after flowering, but it is always best to treat it as a biennial and to sow seeds every year. The seed is very small and is best sown in a pan in June, and kept in a frame until the seedlings are up. When the plants are large enough they should be pricked out into a nursery border of rich soil, and remain there until they are transferred in the autumn to the spot where they are to bloom. The seed-pods much resemble those of the Canterbury Bell, and the second flowers come from the axils of the first as in that plant. A sunny border and a warm, well-drained soil are best suited to its requirements. *S. W. Fitzherbert.*

Fig. 45.—"A crowded corner" in a Donegal garden.

VIEWS FROM A DONEGAL GARDEN.

We are indebted to an occasional correspondent, Miss S. M. Wallace, for the pretty views (figs. 44 & 45) taken in Donegal, of which lough a peep is afforded in fig. 44, with the mountains in the background, while in fig 45 is seen a pretty corner of an Irish flower border in springtime. In this latter picture, the clump of Ferns to the left is planted in a rough piece of Bog Oak, which makes a capital background, and Ferns, Grasses, &c., do well in such situations, if care is taken to water them in dry weather, as the pockets do not afford much room for soil.

Two old favourites—London Pride (Saxifraga umbrosa) and Bachelors' Buttons, with a wealth of Ferns, Heuchera, Forget-me-nots, and Tulips, are all growing with a vigour that shows their sunny corner is in keeping with their requirements.

The views of the old shrubbery and lough (fig. 44) afford a glimpse of Irish scenery. The foliage shows to advantage against the distant lake and mountains, while the dark branches of the copper Beech tone well with the tall, slender growths of Abies Nordmanniana, while the richly-coloured blossoms of Rhododendron Blandyanum are shown off by its white-flowering neighbour. The handsome Gunnera scabra completes the group.

Science and Agriculture.—Germany offers no field for dishonest dealers in cake, mineral manure, seed and meals. The farmers recognise the absolute necessity and the pecuniary benefit bestowed upon them by having due knowledge of chemistry and making use of this science to know how to feed their stock judiciously, produce milk, meat, or muscle, how to feed the crops with certain quantities of nitrogen, phosphates, and potash, and to make use of the many Government institutions established for the welfare of the community. (*Consular Report*, "Agriculture in the Rhenish Province.")

THE HAY CROP OF 1906.

ROTHAMSTED EXPERIMENTS.

The beginning of the year found the surface soil in Mid Herts deficient in moisture to the extent, according to the Rothamsted observations, of about 178 tons of water on each acre of land. January and February of 1906 gave an excess of 2¼ inches of rain, compared with the average; this was followed by three months of deficiency—March, April, and May—aggregated 200 tons of water per acre less than the average amount. The first three weeks of June recorded a further deficiency, but on the night of the 28th over 2¼ inches were measured, which brought up June's rainfall to 3·6 inches, being 1¼ inch in excess of the Rothamsted average for the past 50 years.

The mean monthly temperature was below average in February, March, April and June, but slightly excessive in January and May. The season has been saturated with bright sunshine, which is a characteristic of the year, May being the only month that registered a deficiency. The total sunshine for the first six months of 1906 was, according to the Rothamsted record, 103 hours in excess of the usual average

It has been the nights which have been so exceptionally cold and have brought down the mean temperature, and kept the soil abnormally chilled. The dominating characteristic of the year in Mid Herts has been drought, associated with bright sunshine in the day-time, excessive cold at night, and a consequent chilled, almost freezing soil. These conditions, accompanied by lack of rain during the usual growing period of the mixed herbage of grass-land, has resulted in a much less than average crop of Hay. The splendid rain at the end of June assisted the verdure of the grass-fields, but came too late to greatly increase the bulk. The early grasses, such as Foxtail, Sweet Vernal, Brome grass and Quaking grass, none of which produce very bulky produce, ripened quickly, without forming much bottom herbage. The Leguminous plants, especially Lathyrus pratensis (meadow Vetchling), made but little headway until the end of June, Red and White Clovers were not so vigorous as last year, while the Red Sorrel Dock and Buttercups have been particularly prolific. Owing to the continuous bright sunshine and a moderate force of wind there has been no difficulty in obeying the old adage to "make Hay while the sun shines." The thin crop merely had to be cut and left for a day or two as the machine delivered it, then drawn together with a horse-drag, and with one turning was usually ready for carrying without further trouble. In a few cases, however, we hear of too much haste, which has resulted in "firing of the stacks."

Under the foregoing conditions the Rothamsted experimental grass plots, 22 in number, which have this year grown their 51st crop of Hay under the same manurial treatment, have in all cases given a deficient yield compared with the average, ranging from less than one cwt. to 13½ cwt. of Hay per acre below the average product. The crop grown without manure during the whole period of 51 years was 12·2 cwt. per acre, being 9·1 cwt. less than the average produce of Hay for this plot. With superphosphate alone 14·4 cwt. were obtained, a gain of but 2 cwt. over the unmanured, and 8·1 cwt. below average. The effect of phosphate alone, whether applied as superphosphate or basic slag, if applied for several years in succession, causes exhaustion of the soil nitrogen, so that very poor crops of grass are grown. With the addition of ammonia salts to the superphosphate, a yield of 23·4 cwt. of Hay per acre was obtained; this, however, is nearly 11 cwt. per acre less than the average. Adding sulphate of potash to the phosphate and ammonia, the crop was raised to 39 cwt. per acre, which is 26·8 cwt. in excess of the plot receiving no manure, but is

12 cwt. below the average output. The quantity of sorrel dock (Rumex Acetosa) on this plot this year was most remarkable. Three years ago a dressing of 2000 lbs. of ground lime was applied on one-half of this plot, which has had the effect of increasing the crop to 2¼ tons per acre, and of decreasing the proportion of sorrel. On the section receiving lime, there was also a falling off of but 1 cwt. of Hay below the usual average; such is the good effect of lime even under unfavourable climatic influences. It may be mentioned that on one-half of some other plots of the experiments, lime was applied three years ago with more or less beneficial effect. Where there was no appreciable gain was on the plots deficient in potash. With phosphates and potash applied as manure without nitrogen there was obtained 34.4 cwt. of Hay per acre, a crop less than the average by 1.2 cwt. only. This plot of land has received not one ounce of nitrogen in manure during the whole period of 50 years, and yet it has produced nearly three times the amount of crop over that grown without manure. The fact is that potash and phosphates encourage the growth of Clovers and Vetchlings, which, by virtue of the micro-organisms in the nodules on their roots, get the nitrogen required from the atmosphere, where it exists in abundance if the crops can but assimilate it, which the Leguminous plants, even in grass-land, seem to be able to do. Under these conditions the application of lime increased the crop by seven cwt. per acre; this element combines with the nitrogen-residue in the soil, brought about by the nitrogen collecting clovers, and thus forms nutritive plant food. Lime without humus matter to act upon is of but little benefit, as is shown on plot 8 of these experiments, which receives sulphates of soda and magnesia, with superphosphate, but no potash or nitrogen. Here the crop is reduced to 21 cwt. per acre, being 6 cwt. less than the average quantity. The mixed herbage contains a very small proportion of clovers, not more than 4 per cent. of the whole bulk, consequently there is little nitrogen absorption from the atmosphere, and but little nitrogen residue in the soil for the lime to act upon. Hence there was less crop with the addition of lime than without.

The value of nitrate of soda in seasons of drought is strikingly shown in the Rothamsted experiments, and especially on the mixed herbage of grass land where many of the plants send down their roots very deeply into the subsoil. There is an increase of crop even under the influence of nitrate of soda alone, but when this soluble manure is combined with potash and phosphate, the result is much more marked. In the present season 41 cwt. of Hay per acre were obtained, against 30 cwt. for the corresponding plot receiving ammonia salts.

The heaviest crop of Hay produced this season was grown with a full mineral supply and an excessive amount of ammonia-salts—146.2 lbs. of nitrogen per acre. This gave 61.7 cwt. per acre, showing a deficiency compared with the average of less than 1 cwt. of Hay per acre. The produce consisted almost entirely of grasses, and is made up by three or four of the strongest and coarsest species. The quantity of Hay is, therefore, very inferior, and is not to be recommended for cattle feeding.

It may be stated as a general rule, that to keep up the quality of a pasture cut for Hay every year, a manurial dressing of about 10 tons of farmyard dung should be given once in each four years, and in the intermediate years an application of 3½ cwt. superphosphate or 5 cwt. basic slag, with 4 cwt. kainit or 2 cwt. sulphate of potash, and combined with these not more than 1 cwt. of nitrate of soda. If bulk of produce is required rather than quality, then the quantity of nitrate of soda may be increased to 2 cwt. per acre, but should not exceed this amount. *J. J. Willis, Harpenden.*

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

STORM AT GUILDFORD.—Guildford was visited by such a thunderstorm on August 2 as cannot be remembered in the annals of this place. The gardens here suffered great damage. Hailstones as large as marbles cut the leaves, flowers and fruit to atoms. Vegetables were cut flat to the ground. Nothing but destruction is to be seen. Chrysanthemums and Tomatos are stripped of their leaves. Giant Elms and Oaks over 100 years old in the Park are torn and broken about in such a manner that they will never recover. *R. Staward.*

POLYGONUM SPHÆROSTACHYUM.—Without entering fully into the recent correspondence regarding water gardens, perhaps I may be permitted to make a remark upon Polygonum sphærostachyum, referred to by Mr. Mallett and Mr. Horton with conflicting views as to its cultivation or situation. As one who has known this plant for a long time, and one who has seen it under very different conditions, it appears to me that, although difficult to grow in some places, in others it will accommodate itself to widely differing conditions. I have found it to carry on a lingering existence for a few years in a rather boggy and peaty soil, such as has often been recommended for it, and I have also seen it do well in similar conditions. I have known a good plant, on the third terrace of a somewhat dry rockery, which has thriven there for a good many years, and I have had under observation another doing equally well in a peaty soil and on the level, but in a moist position. I have a plant myself in a dry position about nine inches above the ground level, and planted about a year ago. It is doing well. Regarding the layering the side growths, this is desirable, but not absolutely necessary, as I have seen a good many plants in perfect health without this treatment. Certainly if increase is desired this should be done. The names of P. sphærostachyum and macrophyllum are inappropriate enough, but that is no new thing with plant names. *S. Arnott.*

THE NATIONAL POTATO SOCIETY.—From conversation I have had with several strong supporters of the National Potato Society, I gather that great dissatisfaction exists with respect to the arrangements to hold the third annual Potato exhibition so late as the middle of December. I do not know, although at the time the arrangement was made I was a member of the executive committee, but was not able to attend the meeting held at the Agricultural Hall, why the date was fixed so late; certainly it is according to all precedent not only late, but far too late. When members of the trade who have been in the past strong supporters of the exhibitions, intimate that they can no longer support a show held so late in the year, it is evident that both the Society, which is something, and the interest of the Potato, which is far greater, should have greater consideration than them. The exhibitions of the old International Potato committee, the finest and most successful ever held, were always in the early autumn. Then, too, amateur growers were abundant. These had largely been created by the society, but the present shows the amateur element has not been prominent. Where shall we find nowadays an equal to Mr. Hughes, of Wentworth Woodhouse, who was in the old days a veritable prince amongst Potato growers. We want to see such competitors as he and many others were then, but that can never result if the annual exhibition is made a mere appanage of the Smithfield cattle show. I would suggest that the new secretary and the treasurer join in issuing notice of a meeting of all last year's subscribers at once to consider the question as to the date at which the exhibition has been fixed, leaving the majority to determine a matter of unquestioned importance. *A. D.*

THE LATE WILLIAM CHESTER.—No private garden enjoys greater historical distinction than does that of Chatsworth. Apart from the great palace itself, its noble gardens and glorious surroundings, its name will always be associated with the memory of one of the most celebrated gardeners of the 19th century, Sir Joseph Paxton, as it will also with that of his munificent patron and friend the sixth Duke of Devonshire, the creator of this wonderful garden. The late Mr. Chester, whose death was recorded in the last issue of this journal, would have been the last man in the world to have laid claim to any distinction or particular merit of his own. Mr. Chester was one of the most modest and self-effacing men the writer has ever known, and yet he had good reasons to be proud of his career, although a humble one. He had the unbroken and proud record of serving three dukes over the long period of 52 years. He entered the gardens first when his Grace the present Duke came of age, and he often used to recall with pride the magnificence of the celebration of that day. As a young gardener he passed through most of the departments of the gardens until he was placed in charge of the great conservatory, which charge he retained for very many years; in fact, until his faithful and long services were rewarded in 1891 by his appointment as head gardener. As a gardener he was distinguished by the assiduity and industry by which he discharged all his duties. No man ever entered a garden who was more methodical, regular, and even punctilious as regards the discharge of duties devolving upon him than he was. It used to be a standing joke that Chester was never known to be a minute behind his time in the morning all the years he worked at Chatsworth, and I believe this to be quite true. No doubt the pride of his life was his long charge of the great conservatory, the condition of the contents of which did his labours and care great credit. Anyone who has ever seen the magnificent baskets of Achimenes hanging from the roof of the great house, many of the specimens 5 feet through, simply giant balls of lovely colour, or the equally large and well-grown baskets of Maidenhair and other Ferns, can never forget the sight. He had a special love for Ferns, of which he had a good knowledge, as he had also of Cactaceous plants. He also had the credit of first flowering the Renanthera coccinea in this country, growing it on a piece of Birch-pole suspended from the glass on the west side of the house. Mr. Chester's life was unique in the sense that, during his 52 years' of continuous service at Chatsworth, he became associated in practical work with many of the best-known and celebrated gardeners of the last decade. Mr. Paxton (as he was then) was laying the foundation of his future fame as a great builder of glasshouses and a maker of gardens. Amongst others of his contemporaries of those days were Andrew Stewart (the once famous kitchen gardener there—afterwards succeeded by James Taplin—a stormy petrel of that time), Thomas Speed, and Owen Thomas. Fellow workers of his were also John Gibson, of Battersea Park, Geo. Eyles (the predecessor of A. F. Barron, of the R.H.S.), Milner (of landscape fame), Latham (late of the Botanical Gardens, Birmingham), Bennett, of Rangemore, and a host of other well-known gardeners of their day. Mr. Chester's life has been of a singularly even tenor, a bachelor with no particular care, of a genial and cheerful disposition, and a mind full of pleasant and interesting reminiscenses of the past; a man who made a host of friends and never an enemy. He was followed to his grave at Edensor Churchyard on July 31 by a host of sorrowing friends. *O. T.*

STOCK "MONT BLANC."—In one of the public gardens here we have a border some 40 feet in length planted with this Stock, which I believe was sent out by Messrs. Carter & Co., High Holborn, and being at present in their full beauty they speak eloquently both of their worth as decorative plants and as to their value for town gardens. Further, I never remember having seen or noted such a large percentage of "doubles," not more than a dozen singles appearing in 350 plants. The glistening purity, together with the great size of spike and individual bloom of this variety, render it one of the most valuable and beautiful of garden plants. *Walter H. Aggett, Supt. Public Gardens, Bermondsey, S.E.*

BLACKBERRY "ELDORADO."—I am sending you fruit and foliage of the American Blackberry "Eldorado," which I consider the best of the American varieties. It is an early variety, as you will see by the fruit being already ripe. The foliage is bold and distinct, and the spines are comparatively few: it is a good grower, is thoroughly hardy, and has not the great defect of most American brambles, which often die off from no apparent cause. The fruit is from a small plant transplanted in February last. I have also a variety selected from the Moorland Blackberries of Devonshire, which as a bearer will, I think, surpass the "Parsley-leaved" Blackberry, but of course it is much later in ripening than "Eldorado." *George Pyne, Denver Nurseries, Topsham.*

ROYAL HORTICULTURAL SOCIETY.

International Conference on Hybridisation and Cross-Breeding.

In our last issue we published the proceedings of the Hybridisation Conference up to the time of going to press on Wednesday last.

The proceedings were resumed at the Society's Hall, Vincent Square, on the Thursday morning, Mr. W. Bateson, F.R.S., V.M.H., President of the Conference, again presiding.

The Germination of Orchids.

M. Noel Bernard, of the University, Caen, France, read a paper on this subject. He said on the roots of Orchids, whether wild or cultivated, were found fungi, which, living inside the cells of the outer surface, formed lumps like balls of thread. This fact was well known, easy to observe, and furnished one of the best examples of those associations, very common in Nature, between plants and micro-organisms. He had attempted to estimate the extent of this connection, and the degree of dependence the Orchid and its fungus might have on one another. His experiments showed that the fungi of Orchids could live apart from the roots in which they generally lodged. If a small fragment were cut from a contaminated root and sown in a sterilised tube on a suitable nourishing medium, the spores developed freely. They could be transplanted from tube to tube without losing their power to grow. He had pure culture of spores living after four years, without their having been replaced on the Orchids. He had found three species of these Orchid fungi, but he had not yet named them.

Although the fungi could live away from their host-plants, the Orchids themselves required the presence of their guests for their own development. He had sown the seeds of numerous Orchids aseptically with every precaution; but the grains had not freely germinated, and their growth was insignificant. On the other hand, if spores of the appropriate fungus were sown with the Orchid-seeds, they commenced to germinate almost immediately in a very regular manner. With the fungi which he possessed he had obtained not only the germination of species of Cattleya and of Cypripedium, but also the germination of species of Odontoglossum, Phalænopsis, and Vanda, which were regarded by practical men as more difficult. In Nature or in the glasshouse the same thing took place as in the culture-tubes. He had examined a large number of young Orchids which had germinated in very varying conditions, and he had always noticed that they were invaded by the fungus from the beginning of their life. The Orchids were therefore practically dependent on their parasitic fungi, since they did not grow without them. One of the greatest difficulties was to procure the fungus suitable for each kind of Orchid. As a rule, he used the fungi collected from the roots of an Orchid of the same species, or of one nearly allied to that which bore the seeds. That was the best rule he could give, but it might not be an absolutely sure one. Making all reserve necessary in a subject so complex, he believed it was possible that the mere change of the fungus might result in a variation of the species of Orchid in question. The extension of the researches would possibly one day indicate to practical experimenters new ways in the rational methods of culture of a large number of plants, as Orchids were not by any means the only plants which lived in association with fungi.

The U.S.A. Department of Plant-Breeding.

Dr. Erwin Smith, of the Department of Agriculture, Washington, U.S.A., followed with a paper on the work of his department. He said he was a substitute for Dr. Webber, who was unable to be present. The department had been working in the direction of finding a resistant to disease, notably in the Cotton plant, the Water Melon, and the Grape vine; resistance to frost in the case of the Orange and similar fruits; resistance to alkali in the soil; greater productivity and better quality in the flesh of fruits, Wheat, and other products of commercial importance, such as tobacco, cotton, and Maize. They had been highly successful in all cases. For instance, they had produced cotton twice as productive as ordinary cottons, and, in the case of Tobacco, they had obtained remarkable results, as by crossing they had obtained from an inferior quality a leaf undistinguishable from the best Cuban Tobacco leaf.

The Hybridisation of Trees.

Mr. Elwes said he had proposed to speak on this subject later, but he would say what he had to say at this point, as it was apposite to the paper just read. It was difficult to deal with the question of the hybridisation of trees from an economic point of view on account of the time necessary for their culture, but he believed they knew sufficient of the subject to suggest that the planting of trees which had been hybridised should be brought before the Government for serious consideration, exactly as was being done by the U.S. Government. He did not suppose they could prove much in their lifetime, but he could not admit that the subject was out of the question as a scientific matter.

Mr. W. Carruthers, F.R.S., said it was a matter for regret that we seemed to be behind almost every other country in the world in this matter, and he hoped that Dr. Smith had kindled a torch which would not soon be put out. The President of the British Association wished to get ten millions a year for scientific research. He was quite sure the R.H.S. might very well ask for, say, one-fifth or perhaps even one-tenth of that sum for the purpose of carrying out investigations.

Mr. Geo. Gordon said we in this country had been trying for many years to grow Maize as a table vegetable, but with very little success; but a friend of his obtained some Maize from America, without name, but possibly some of the hybrids referred to by Dr. Smith, and it had grown amazingly.

Dr. Smith said fields which were once worthless were now growing good Cottons.

Hybridisation of the Sugar Cane.

Sir Daniel Morris, K.C.M.G., V.M.H., of Barbados, West Indies, addressed the Conference on the "Hybridisation of the Sugar Cane." At one time, he said, all canes were propagated by cuttings, but in 1888 it was discovered, or, rather, re-discovered, that some varieties of cane produced seed. Experiments were carried out, the best canes were selected, and it might be considered that the seedling cane started from that time. The Otaheeti canes had been cultivated up to 1888, but they were attacked by a serious disease, and means had to be found to combat it. The re-discovery came in just at a time when it was wanted. Had it not been for the discovery of seedling varieties Sugar canes would practically have gone out of cultivation. During the last eight years great developments had taken place in the West Indies. The Department of Agriculture there was provided by the Government with £20,000 for its maintenance. Years ago he suggested to our own Government that a grant should be made to that department, but nothing was done until Mr. Chamberlain took the matter up. He was glad to say that they received great assistance from the United States Department, especially in connection with the production of Cotton. As to the seedling canes, they had distributed them to Cuba, Porto Rico, Mauritius, Natal, and parts of India, and everywhere the production had been enormously increased without any extra cost, owing to the cultivation of the new seedling canes. While they were increasing the output and the richness of the Sugar, they were also doing much in making the canes disease-resisting. In Java and elsewhere they had been most successful in cross-fertilising by hand. In conclusion, Sir Daniel read an extract from the final progress report of Professor Harrison, which stated that, owing to the Imperial grant-in-aid (which ceased to be payable from March, 1906), the area occupied by new seedling varieties in the West Indies had extended from 550 acres in 1899 to 20,065 in 1906, and that, during the last five years, the new varieties of seedling canes had given, over large areas, mean results of 8, 19, 22, and 35 per cent. higher than the average of the returns obtained from the Bourbon during the same period.

On the motion of Mr. Elwes, seconded by Sir Daniel Morris, it was decided to send a resolution thanking the United States Department of Agriculture for what they had done for the West Indies.

Sugar Beet.

M. Philippe de Vilmorin, of Paris, addressed the Conference on "Selection and Growing of the Sugar Beet," and on "Hybrid Wheats," subjects in which his father and grandfather had made such important experiments.

Oats, Barley, and Wheat.

Professor C. A. Zavitz, of Guelph, Canada, spoke on the breeding of these cereals. Among other things he said they had now had some 16 years' experience of Oats. One variety they obtained from Russia was now giving an average of 16 bushels per acre per annum more than the variety grown extensively throughout Ontario. That was due to proper selection of seed and the greatest care exercised in all other directions. The question was often asked, was it necessary to change the seed from one soil to another and from one climate to another? They were growing the same variety of Oats, or Wheat, or Barley on the same land for as many as 16 years without deterioration in the yield or quality. That was a very important point. Professor Zavitz displayed, among others, the accompanying diagrams:—

Ontario Agricultural College.
Selection of Seeds and Plants.

Kind of Crop.	Production of Selected		Produce of the seed in three seasons		
	Seeds	Plants	1903	1904	1905
	Lbs. per Bls. per acre.	acre.	Ozs.	Lbs.	Lbs.
Six Rowed Barley (Ward's Chevalier)	68·4	78·3	2·3	68	1,929
Two Rowed Barley (French Chevalier)	44·8	58·6	2·4	56	1,319
Hollien's Barley (Grey Mavle)	47·3	48·6	2·9	98	2,109
White Oats (Siberian)	86·1	91·3	1·6	61	2,102
Black Oats (Ivanette)	79·3	89·6	1·2	74	3,430
Spring Wheat (Wild Gorse)	29·7	36·4	1·0	15	242

So that the introduction of one Barley was worth millions of dollars to Ontario.

Mendel's Laws and their Application to Plants.

Mr. R. H. Biffen, of Cambridge, read a paper on "The Application of Mendel's Laws to the Improvement of Cultivated Plants." He said the whole Wheat industry in this country was in an extraordinary condition, and cried aloud for improvement. Any miller would tell them that there was no English Wheat cultivated at present which possessed what the miller termed "strength"—the capacity to give a loaf which should be light, white, and a type of loaf which the general public demanded now; in fact, the miller would go further and say that there was not a single variety of Wheat in cultivation which would give even a passably good loaf. The consequence was that the price of English Wheat had fallen sadly, and if things went on we should soon be in the position of having no Wheat crop left in this country. The outcome of investigations had been this—that there were a large number of strong Wheats which retained their characteristic strength in this country, and, on the other hand, there were a much larger number of strong Wheats imported into this country which deteriorated at once, and became, if possible, worse than the English varieties. Although it had been shown that we could grow strong Wheats, the "find" was not so important as was thought, because in one of these strong Wheats were sufficiently good, from the farmer's

point of view, to cultivate profitably. The yield was not sufficient to pay for the farming, the straw was not satisfactory, and they ran the risk of losing the crop owing to the yellow rust.

By applying Mendel's laws and crossing with proper varieties, he had succeeded in increasing the quality and output and in conquering the yellow rust. It had been stated that, owing to the yellow rust, Germany lost annually some 20 millions pounds sterling, and it had been estimated that the world was losing yearly no less than 100 millions through the attacks of the rust. He would not vouch for those figures. Personally, he did not believe in their accuracy; but he did believe that very great loss was entailed, and that the application of Mendel's principles would put a stop to it.

A discussion ensued on the foregoing group of papers on cereals,

Mr. Elwes agreed that the subject was extremely important. Speaking as a practical farmer, he said that unless experiments were going to give the farmer what he required, he might waste much time in working for a result which would not be of so much a practical as of a scientific value. Modern milling required two qualities—strength and colour—strength being the ability to absorb water. As long as water was cheaper than wheat, the interests of the miller could not be the interests of the consumer. English white Wheat would make the best bread. For himself, he grew for straw. It was worth as much as Wheat. When Barley straw could be sold at £4 a ton, and Russian Barley bought at £3 16s. for feeding the cattle, they could not ignore the question of straw.

M. Philipe de Vilmorin said that in France they tried fine white Wheat. It stood well, but generally it had a short straw. The definition of "strength" was vague, and had nothing whatever to do with the actual chemical composition of the gluten.

Professor Wittmack said he thoroughly appreciated Mr. Biffen's paper. Strong Wheats could not be grown in climates like that of England. English wheat could not become rich in gluten, for the season was so long that starch was formed owing to the long period of vegetation. Where there was a short period of vegetation, starch was not formed, and the proportion of gluten would be all the greater.

M. Phillipe de Vilmorin said that Fife was a quick-growing variety. It was not a Canadian Wheat, as Professor Wittmack seemed to think, but a German variety.

THE AFTERNOON MEETING.

At the opening of the afternoon session the Chairman handed to the Conference what he described as a remarkable specimen of Rosa sericea pteracantha, cultivated by M. de Vilmorin. It was a species imported from China, remarkable for its brilliantly-coloured prickles, as lately figured in the *Gard. Chron.* He also showed to the Congress a specimen of Dipsacus from Dr. Masters' garden. The seedlings of the twisted variety were found by Dr. de Vries to reproduce the twisted condition to the extent of some 80 or 90 per cent., but Dr. Masters had grown the plants originally derived from Professor de Vries for a succession of years without even seeing a twist in the stem, except in one instance, where he had purposely subjected the plant to frequent mutilation during growth and obtained in consequence a slight twist which so far had not been reproduced in the young plants derived from it.

THE SWAMP POTATO.

Prof. L. Wittmack, of the Royal Agricultural College, Berlin, read a paper on "Solanum Commersoni, the Swamp Potato," which, he said, was found on the *eastern* coast of South America—*not* on the western coast. The Professor went into the history of the Potato, and said they were standing in the presence of a riddle. There were many who thought that the Blue Giant Potato originated from Solanum Commersoni, but others doubted that. If what M. Labergerie said was correct and he did not doubt it they had in Solanum Commersoni a plant which, to use the expression of De Vries, had just come to a state of mutation, and that was certainly caused by the better culture it had received at the hands of M. Labergerie. They would have to wait for more definite results. The Professor displayed several specimens he had received from Messrs. Sutton.

Dr. Erwin Smith (Washington) admitted that he was perplexed.

M. P. de Vilmorin said that Messrs. Sutton had done much to elucidate the problem. It was impossible, he said, for two plants differing in botanical characters to mutate without the intermission of one seedling. There was no instance of [direct] transformation of one species into another.

The Chairman said he believed in mutation, but to believe that the Labergerie Potato was produced as a sport from S. Commersoni was to his mind impossible.

AMERICAN FLORISTS' IDEALS.

Mr. John H. Troy, delegate of the Horticultural Society of New York, read a paper on "Florists' Ideals in the United States of America." Apart from the academic interest in plant-breeding, there was an intensely practical side of the question, and upon the other side of the Atlantic this aspect of the whole subject of plant-breeding received a far greater consideration than did the other. They might be even too practical in America; at all events, their plant breeders set out with extremely high ideals. It was not an excuse for the introduction of a new form that it was merely different from other things; from their ultra-utilitarian standpoint they insisted that it should be better. It was for this reason that economic crops had received, and were receiving, such close attention from their own Government Department of Agriculture. Among other things, they were seeking for disease-resisting varieties, which would put into the hands of the cultivator the means of livelihood at present barred. He added that the American market stood wide open to any flower or plant which would meet their high ideals, but it was no place for the curio raiser to send his productions to, as there was no demand for a thing purely on the ground of intrinsic novelty.

AURICULA AND CARNATION.

Mr. James Douglas, V.M.H., of Great Bookham, Surrey, read a paper on "Cross Fertilisation of the Auricula and of the Carnation." The Auricula, he said, was an old-fashioned favourite, and highly interesting as a garden plant. If they could trace its origin, an interesting problem would be solved. Had the Conference been held in April, he could have exhibited a series of Auricula plants in bloom which would have demonstrated to some extent the variability of the cultivated Auricula and its not infrequent reversion to what might be supposed was its original source. The Auricula had been cultivated in gardens for upwards of 300 years, and they could trace its gradual improvement to the edged form through many years of patient culture. It was generally conceded that the origin of the edged Auricula was Primula Auricula, and the origin of the Alpine Auricula, Primula pubescens; but it had been pretty well proved by evidence obtained from specimens found in the Tyrol that P. pubescens itself was a hybrid between P. Auricula and P. hirsuta. The Alpine Primulas were difficult subjects to cultivate and establish in our gardens, and the same difficulty was experienced 300 years ago.

The Carnation, like the Auricula, was exceedingly variable in its character, and constantly reverted to its original source, or, rather, to the single form which was still to be found on old castles in Normandy, and probably it yet lingered in England, where it had been found growing with its roots searching for a scanty subsistence amongst decaying mortar, and humus in small quantities. The gardener took in hand the progeny of this wilding (which had been improved by ages of cross-breeding and selection); but in many cases the result of over-feeding in Carnations was the same as over-feeding in men and animals—disease attacked the plants sooner or later, and in some cases it was difficult to eradicate it. How the wild Carnation (Dianthus Caryophyllus) had been trained to its high state of perfection it was not easy to say. Hybridisation was not necessary; indeed, it was unlikely. The plant might have been introduced to gardens from its native habitat. Cultivation would soon produce seedlings of varied forms and colours. Some of them would have an extra petal or two, and, saving seed from these by a process of careful selection, semi-double and double flowers would be produced of various colours. This process, as was well known, took much longer in the case of a plant like the Carnation than in that of such a fugacious flower as the Poppy. The Rev. W. Wilks found a variation of the common Poppy in his garden, and, with the instinct of a true gardener, he saved seed from it, and next season the variation was greater, and he set himself the task of changing this noxious weed into a beautiful garden flower. This was an excellent example of what could be accomplished in a few years by one earnest and careful cultivator. The name of the gardener who first obtained a break in the wild form of the Carnation was lost in remote ages. Some thought the Romans brought the Carnation into England, but they did not read much about it until the reign of Elizabeth, when in 1550 Wm. Turner published a Herbal which was dedicated to that monarch. Turner recorded that the flowers had taken on the double form, and added that they were "made pleasant and sweet with the labours and wit of men, and not by nature." The Picotee was merely a coloured variety of the Carnation, but was distinguished from it in having a ground colour of white or yellow with a narrow margin of colour round each petal. A perfect Picotee should have no spots or colour on the petals except the fine line or broader margin of colour. The Carnation might be hybridised by any species of Dianthus. Mr. Douglas added that he understood little of Mendel's Laws, but he knew what he wanted, and generally got it!

AMARYLLIS AND OTHER HYBRIDS.

Mr. A. Worsley, of Isleworth, followed with a paper on "Hybrids Among the Amaryllideæ Cactaceæ, Gesneraceæ and the Genus Senecio."

The Chairman said that Mr. Worsley had mentioned the absence of dominance in the cases he had investigated. It was essential to Mendelian results that there should be a dominance. Mr. Worsley also spoke of a Cineraria as self-fertilised. He supposed there was no doubt about that, as he had found it largely sterile.

Mr. Worsley said every precaution was taken, and there was no doubt about the plant being self-fertilised.

COLD-RESISTING FRUITS.

Prof. N. E. Hansen, of the South Dakota Agricultural College, U.S.A., read a paper on "The Breeding of Cold-Resisting Fruits." He said that it had cost the States many millions for European Apples, which, after all, were of no use in cold regions. A great work was going on and they were producing harder varieties. The same could be said of Plums. Cold-resistance was the characteristic transmitted by crossing. The same was done with Strawberries, and he was raising Strawberries that would stand a cold which froze mercury.

The Chairman: Do I understand that the Strawberry goes on bearing when mercury freezes?

Dr. Hansen: The Strawberry plant lives through it.

The Chairman: Well, that is sufficiently remarkable. I am glad we have none of those difficulties.

THE BREEDING OF FRUITS.

Mr. H. Somers Rivers, of Sawbridgeworth, prepared a paper dealing with the "Breeding of Fruits." At the outset he complained that there was no direct commercial gain to justify any great outlay in obtaining new fruits. When a new fruit was once known, and of proved value, it was quickly propagated, and the raiser had no monopoly. He then went on to deal with Peaches and Nectarines, since it was with regard to the cross fertilisation of these that he had the fullest data. The time which elapsed before a seedling tree could be judged by its fruits and the space it occupied whilst arriving at maturity militated against experiments being carried on on a sufficiently large scale. From the Peach blossom which had been cross fertilised this spring they might confidently expect to be able to judge the result of the combination ten years hence if nothing untoward had happened to the seedling in the meantime; possibly a year or two sooner! The seeds did not always germinate the first year. To ensure this early fruition of one's hopes, the tree must be carefully tended and grown

under glass; by the time it was four or five years old it took up as much room in the orchard house as would a pot tree which was giving a good crop of fruit, and required as much attention. Probably, after all, the new variety would have no especial merit to warrant its retention, and being of no use for firewood, the tree would be burnt on the rubbish heap! The work needed great patience; it was a labour of Sisyphus, but the stone occasionally lodged on the top of the hill! Darwin argued from the supposition that the Peach was derived from the Almond, but his arguments were not very conclusive. If this were so, one might reasonably suppose that amongst very numerous seedlings cases of reversion would occur. Mr. Rivers said he had never noticed any but true Peaches and Nectarines. Darwin further said: "Whether or not the Peach has proceeded from the Almond, it has certainly given rise to Nectarines. Most varieties, both of Peaches and Nectarines, reproduce themselves truly from seed." The following were the results of 35 crosses:—

1. Peach ♀ × Peach ♂ = 5 Peaches 1 Nectarine.
2. Peach × Nectarine = 5 Peaches 3 Nectarines.
3. Nectarine × Peach = 8 Peaches 2 Nectarines.
4. Nectarine × Nectarine = 0 Peaches 11 Nectarines.

From this it would seem that the Peach was dominant. The 11 Nectarine by Nectarine crosses yielded Nectarines, notwithstanding the fact that in 10 of them either the seed, or pollen, parent of both had Peaches amongst their immediate or remote seed parents. Having given the results of other experiments, Mr. Rivers said he could not venture to dogmatise on the above results. No doubt a longer series of recorded crosses would allow definite deductions to be made.

Protection for Raisers of Novelties.

Mr. George Paul then said they could hardly separate without referring to a matter of the greatest interest to them all. He thought there should be some protection for raisers of new varieties. Many well-known raisers were absent that day. The fact was that gentlemen who made experiments did not want to lose the rewards of their labours by making their experiments known. If they had some protection they would be perfectly willing to come forward and state their experience. He had raised a good many things in his time, and some present would be astonished to know the value of a new Rose; £50 or £100 was the total, out of which had to be defrayed the cost of advertising and the cost of the catalogue. He certainly thought they should pass a resolution calling for State protection.

Professor Hansen said he feared there would be some difficulty in the matter. He believed that in law a seedling was regarded as the gift of God, and it would be hard to patent it.

The Chairman suggested that it would be unwise to pass a resolution unless they could give some indication as to how legislation could be enforced.

Mr. Paul said perhaps the certificate of the R.H.S. to the raiser would be a protection.

Professor Wittmack seconded the resolution, saying that the matter in Germany was in the hands of their agricultural society. A buyer of a novelty from a trader dare not sell it within the next three years, so that the raiser might obtain some reward.

Rev. Mr. Wilks: That is by agreement.

The Chairman: You do not contemplate legislative interference?

Professor Wittmack: No.

Mr. Douglas regarded the suggestion as another form of "protection," which the country had already repudiated. He believed in "free trade" in flowers.

Mr. Druery thought there would be enormous difficulty in applying anything like the principle of copyright to plants and fruits, as two or three men might produce the same thing at the same moment.

After some further discussion there seemed to be some misunderstanding as to whether the resolution sought for legislation or not, and on the motion being put many abstained from voting. The motion was rejected by 6 to 5.

Among other papers were Herr F. Burger, of Halberstadt, Germany, on "The Pelargonium" (read by the Assistant Secretary); and A. Paul, of Waltham Cross, on "Varieties of Roses."

The Banquet.

After the Conference the delegates were entertained at a banquet in the hall of the Society. Sir Trevor Lawrence presided.

The Veitch Medals.

In proposing the loyal toasts, Sir Trevor coupled therewith the name of the Queen of Holland, whose birthday anniversary occurred that day. He next rose to present a series of medals. The first were, he said, the Veitch Memorial Medals, which were instituted in memory of the late James Veitch, of Chelsea, and were awarded by the Trustees in recognition of the recipients' work on behalf of horticulture. The first medal went to the President of that Conference, Mr. Bateson. It would have been impossible for any Conference to have had a better chairman. (Cheers.) The next medal went to Professor Johannsen for his discovery of the effect of ether in advancing the inflorescence of flowers. The third medal went to Professor Wittmack, who for many years had been devoted to systematic and practical botany. If the day consisted of 30 hours instead of 24, the President said, he could not enumerate all that the Professor had done for horticulture. The next medal, and the last of the series, he had the honour to offer to M. Maurice de Vilmorin. Everybody was acquainted with the firm of which the Professor was a member. There were two other medals presented by the Society, one of which was to a lady, Miss Saunders, the lecturer on botany at Newnham College, Cambridge. The Gold Banksian Medal had also been awarded to Miss Saunders for her studies on the inheritance of plants. The last medal was awarded to Mr. B. H. Biffin for his researches and discoveries in connection with the Heredity of Cereals.

Sir John T. Dillwyn-Llewelyn proposed the "Foreign and British members of the Conference." The visit had been a useful as well as a pleasant one, and their recollections of their visit to Burford on the previous day would be among the pleasantest of their memories. It had been said that the man was a benefactor to his country who made two blades of grass grow where one grew before, and he thought the work that had been done by the Royal Horticultural Society in bringing together scientific men on the one side and practical men on the other had been a justification for that Conference. It was impossible for any horticulturist not to recognise that in all branches of horticulture a most valuable work had been done by the Hybridist, the Botanist, and the man of science when they joined their forces. The work of the Conference had been fully justified. Much had been done since they held their last conference; so much, in fact, that it necessitated their being called together on the present occasion, and he challenged anyone to say that the meetings of the Conference had not been productive of a great practical work under the able superintendence of Mr. Bateson.

Dr. Hansen was the first to reply. He said, on behalf of the United States Department of Agriculture and his brothers across the seas, he thanked them for their most cordial greeting. What did that Conference mean? It meant that a development of plants and plant-life was becoming an exact science, and that what was formerly a chaos of empiricism was now becoming one of the exact sciences due to recent discoveries in heredity. A clear path had been blazed through the jungle of heredity. New and valuable forms of plants might spring like Minerva full-fledged from the head of Jupiter. He spoke of what the United States Department was doing for Agriculture and Horticulture. It was searching the world for plants better adapted to the various parts of the United States, from Alaska to Southern Florida. The result was that material was secured, and crossing and selection improved that material still further. He again thanked them, and wished the Society all success.

Dr. Tschermak, of Vienna, expressed on behalf of the German and Austrian delegates their deep gratitude for the cordial reception by the society and its Fellows. As an Austrian, he had gladly accepted the invitation extended to his country, and was convinced that the latest developments in the study of hybridisation had been of the greatest interest to the Conference. He had, in company with Prof. De Vries and Prof. Correns, been able to rediscover the Mendelian laws which had so long been neglected. Since then the conditions of the study had been changed by a long series of memorable discoveries, and in England Mr. Bateson had rendered the greatest services to the furtherance of the science of genetics.

M. Philippe de Vilmorin said in France they were not accustomed to after-dinner speeches—an art which was with them of a "recessive" character. The good luck they as scientists enjoyed was not because they dealt in abstract fancies, but because they dealt with things which ladies excepted—were the most fascinating gifts of creation. Every day they lived in close contact with nature, and while benefiting others they profited themselves by the contemplation of nature's beauties. Speaking for himself, when he came to the Conference he was rather doubtful as to the validity of Mendel's laws, but after hearing the papers—especially Mr. Biffen's communication—he was now and would be for ever an apostle of the theory. In conclusion, M. de Vilmorin, on behalf of the Horticultural and Botanical Societies of France, invited the R.H.S. to pay a visit to and hold a conference in Paris.

Sir Michael Foster, K.C.B., F.R.S., was the last to respond to the toast. He said the Conference had been in many ways a remarkable one. It had not attempted to interfere or in any way lay down the lines which this or that nation should follow. He himself did not believe in central international committees which marked out work to be done by this or that nation. He believed that the development of differences was the true basis of unity, as they had already arrived at partial unity by each going its own way.

Mr. W. Bateson (Chairman of the Conference) proposed "The Board of Agriculture, Horticulture, and Fisheries." It was, he said, a great honour for him to propose that toast, because he could not think that in any way they in Cambridge had yet done anything to benefit horticulture. Had it not been for the work done by his friends and pupils and first of all by his colleague, Miss Saunders, whose name had been honoured that night there would have been nothing to justify him in speaking. Turning to the toast, Mr. Bateson went on to say that, as he entered the hall, Sir Thomas Elliott said to him: "I hope you are not going to say 'ditto' to Prof. Ray Lankester, who has asked for 10 millions to fight disease." (Laughter.) Well, he was going to say "ditto" to Prof. Ray Lankester, though, perhaps, with some modifications. They might not all agree in the first place as to the best way of spending the money, but they would be perfectly willing to consider amendments. A precise knowledge of the laws of heredity would give a man a power over his future which no other science had yet endowed him with. He would not say that that knowledge was going to create the millennium for the human race; he would only say that it would change man's destinies profoundly whether for good or evil the future alone would show. He could not expect to see the results in his own lifetime, but the younger generations would see them, and they hoped that the department with which Sir Thomas Elliott was connected would help to make the intervening time pass away quickly.

Sir Thomas Elliott, in reply, said his department fully recognised the great work science was doing. He thought his Board had done something in the direction indicated by Mr. Bateson. They had studied animal pathology, with the result that they had absolutely stamped out most of those serious diseases which once decimated the herds and flocks of this country. He could say the Board had brought about the millennium of the bovine race. Lord Carrington, the President of the Board of Agriculture, was extremely sorry he could not be present, and believed, with all those associated with him, that the work being done by the scientists would confer the greatest benefits on mankind.

Viscount Mountmorres proposed the toast of "Sir Trevor Lawrence, Bt., K.C.V.O., V.M.H., President of the Royal Horticultural Society."

Sir Trevor Lawrence, in responding, disclaimed all merit for resuscitating the Society. The British people, he believed, were really heart and soul devoted to the innocent, delightful, and charming pursuit of gardening, and it was really to that that the success of the Society was due. They owed a great debt of gratitude to their foreign visitors, and he was sure they all trusted they would be able to accept the kind invitation of M. Philippe de Vilmorin. Referring to what the President of the Conference had said, he thought it was beginning to be clearly understood on all sides that unless we in this country took more interest in science we should certainly be left behind in the world. In conclusion, Sir Trevor paid a high tribute to the services of their Secretary, Mr. Wilks, who took an enormous amount of trouble on behalf of the Society.

MISS SAUNDER'S PAPER ON STOCKS.

Owing to the nature of the spacing in the following table as printed in these pages last week, readers may have found it difficult to determine its exact meaning. We therefore reproduce the table:—

(1) Any glabrous sap-colour × any glabrous sap-colour.
F_1 = all sap-coloured glabrous.
F_2 = all sap-coloured glabrous.

(2) Any glabrous sap-colour × any glabrous non-sap-colour (white or cream).
F_1 = all sap-coloured hoary.
F_2 = 9 sap-coloured hoary; 3 sap-coloured glabrous; 4 non-sap-coloured glabrous.

(3) White glabrous × cream glabrous.
F_1 = all sap-coloured hoary.
F_2 = 9 sap-coloured hoary; 7 non-sap-coloured glabrous.

VISIT TO GUNNERSBURY AND KEW.

On Friday the delegates visited the delightful gardens of Mr Leopold de Rothschild, at Gunnersbury. Unfortunately the host was absent in Switzerland, but the guests were received by his son, Mr. Lionel de Rothschild. After walking round the beautiful gardens, the visitors returned to the house, where they were entertained in the double drawing-room at luncheon.

Dr. Erwin Smith, in the names of the foreign delegates, thanked their hosts for all the kindness that had been extended to them.

Sir Albert Rollit joined in the thanks on behalf of the English delegates, and remarked that the advantage of such international gatherings could not be exaggerated.

In the other room similar thanks were expressed.

Professor Johannsen said the gardens were really glorious.

Dr. N. E. Hansen said that they had been the guests of the R.H.S. all the week, and the flower of hospitality was in full bloom that day. He had never seen more beautiful specimens of landscape gardening.

Mr. Robt. Fenn also joined in the vote of thanks.

Mr. Lionel de Rothschild acknowledged the votes of thanks, and said his father wished him to tell them how sorry he was he could not be with them that day.

On their way to Gunnersbury the visitors were taken to the National History Museum of Kensington, where Dr. Rendle and Dr. Smith Woodward acted as guides the former to the Botanical section, and the latter to the Geological section. After luncheon at Gunnersbury the visitors went to Kew Gardens, where tea was served on the lawn.

Thus was brought to a close one of the most successful and certainly one of the busiest and most useful weeks in the history of the Royal Horticultural Society.

BISHOP'S STORTFORD HORTICULTURAL.

AUGUST 1.—The 37th show of the above society was held on this date in the grounds of The Grange, kindly lent by John Barker, Esq., J.P., who is a warm supporter of the society. The exhibition was a great success in every way, and from a horticultural point of view the exhibits were superior to those of previous years.

A large tent was devoted to floral displays, such as dinner tables, and cut flowers. Competition was strong, there being no fewer than 25 entries for decorated tables, and it was pleasing to note that many showed much originality. The classes for dinner tables were restricted to ladies, the 1st prize being secured by Miss BLYTH, of Stanstead, for a charming table decorated largely with Bougainvillea; 2nd, Miss CLAYDEN, Saffron Walden.

Plants.—Groups of plants arranged for effect were pretty though not numerous. The prize in the largest class was won by Col. ARCHER HOUBLON (gr. Mr. Harrison); 2nd, JOHN BARKER, Esq. (gr. Mr. W. Beech), with a heavier arrangement. The class for a smaller group was well contested, Messrs. G. BARNES, WILBY and HOLLANDS receiving the awards in the order named. Mr. BARKER and Mr. W. SMITH both had fine groups of Begonias; the last-named exhibitor, who is usually in the front for these plants, was this year a close 2nd. For Begonias in basket Mr. SMITH won the 1st prize.

In the class for a group of early flowering Chrysanthemums, Mr. G. B. GRIPPER was a good 1st. Good plants were staged in the class for 12 plants in bloom and six foliage plants, Mr. J. WOODS being 1st; 2nd, Mr. BARKER. The same exhibitors were successful in the class for Ferns. Mr. WOODS staged the best Coleus, while Mr. BARKER had the best Fuchsias and the best table plants.

Cut Flowers.—Much space was occupied by these. Strong competition was noticed in most of the classes. The season is not advanced enough for such things as Asters and Chrysanthemums, and the space allotted to these flowers might, with advantage, have been given to other things. In the open class for 24 bunches perennials Messrs. PAUL & SON, Cheshunt, had the finest blooms, Mr. H. C. PULHAM being 2nd. The displays of Sweet Peas occupied much space. Both Mr. HICKS and Mr. BARKER had splendid material in the class for 12 bunches. Prominent winners in the other classes for these flowers were Messrs. ABBOTT, HARRISON, HICK, and KENDALL. Mr. R. B. SMITH had the best 12 show Dahlias, Mr. BARKER the best single Dahlias, and Mr. W. SMITH the best Cactus Dahlias. Mrs. GEE was a good 1st for herbaceous Phlox. Roses were not of exceptional quality; Mrs. A. TAYLOR and Mr. BARKER had the best stands, the flowers though small being very fresh in appearance. Carnations were plentiful and good; Mr. BARKER showed splendid examples of these flowers.

Fruit.—The exhibits of fruit were remarkably good, and the hardy varieties required much space, for, though full early for some kinds, there was no lack of dishes. In the large class for a collection of eight dishes, Col. A. HOUBLON won, having perfect Grapes, Peaches, Nectarines, and Melons; Mr J. BARKER was a close 2nd. For four varieties the same gentlemen received similar awards. Mr. A. JEFFERIES and Col. A. HOUBLON had the best Black Grapes, both showing the variety Madresfield Court. Col. HOUBLON showed the finest Muscat of Alexandria, while Mr. J. BARKER showed the best White Grapes of any other variety than Muscat. Col. A. HOUBLON exhibited the best Melons and the best Peaches. Mr. BARNES won for Nectarines, and the above-mentioned exhibitors were successful in the classes for hardy fruits.

Vegetables.—These occupied a large tent and were of fine quality. Numerous exhibits were displayed by amateurs and cottagers, their produce being excellent in every respect. Mr. A. JEFFERIES was a good 1st for a collection of twelve varieties of vegetables, Mr. J. BARKER being a close 2nd. Mr. KENDALL was successful in the smaller class.

Honorary exhibits contributed greatly to the success of the show. Messrs. RIVERS & SONS, Sawbridgeworth, put up a grand group of fruit trees in pots. Messrs. PAUL & SON showed Roses and herbaceous flowers; Messrs. WALLACE & Co., Colchester, exhibited Lilies and hardy herbaceous flowers; Mr. AMOS PERRY, Winchmore Hill, London, N., had a beautiful array of Nymphæas, Yellow Arums, and other herbaceous flowers; Messrs. BURCH, Peterborough, showed Roses; Mr. KING, Coggeshall, showed Sweet Peas; Mr. R. W. CHAPLIN, Waltham Cross, put up a group of cut Roses; Messrs BATH & Co., Wisbech, had Roses and herbaceous flowers; Messrs. W. COLCHESTER displayed cut flowers; and Messrs. BLACKMORE & LANGDON, Twerton, near Bath, remarkable blooms of tuberous-rooting Begonias. *G. W.*

MIDLAND CARNATION AND PICOTEE.

AUGUST 1, 2.—The sixteenth annual show of the above Society was held on these dates under most favourable climatic conditions. The show was larger and better than that of last year; the exhibits were of high quality and they were well arranged, the arrangements being complete in every detail. The date of holding the show appears to be the time suitable to most exhibitors in the Midland districts, and also to many further north, resulting in a thoroughly representative show. Honorary exhibits gave additional interest to the show, and they were greatly appreciated by the visitors, who do not all understand the critical points of Carnations and Picotees. The classes were arranged to meet the tastes of all lovers of these flowers, and although the florists were prominent with their dressed flowers on cards, it was apparent there is now a strong leaning towards exhibiting these flowers in vases without the use of cards.

Single Blooms on Stands.—The class for twelve self Carnations of dissimilar varieties was won by Mr. A. W. JONES, Stechford, the similar smaller class for six flowers only being won by Rev. C. A. GOTTWALTZ, Droitwich. Mr. JONES was also 1st for twelve yellow ground Picotees in dissimilar varieties, being followed by Mr. C. H. HERBERT, Acocks Green. The best half-dozen yellow ground Picotees, dissimilar, were those of Mr. H. NORMANSELL, Edgbaston; 2nd, Mr. J. KEEN, Southampton. Mr. JONES was again to the top for twelve fancy Carnations of dissimilar varieties, beating Mr. W. H. PARTON, who was placed 2nd. Mr. C. ALCOCK, Liverpool, showed the best six fancy Carnations in distinct varieties; 2nd, Rev. C. A. GOTTWALTZ. Messrs. W. PEMBERTON & SONS, Walsall, were to the fore in the class for twelve white ground Picotees, dissimilar, the 2nd prize being awarded Mr. W. H. PARTON. Mr. F. W. GOODFELLOW, Walsall, had the best six white-ground Picotees in the smaller class. The best dozen flaked Bizarre Carnations of dissimilar varieties were those put up by Mr. C. H. HERBERT; while the premier half-dozen blooms in the similar smaller class were shown by Mr. R. G. RUDD, Birmingham. Mr. PARTON was a prominent winner in the classes for Carnations shown without cards. He took 1st prize for twelve self Carnations, dissimilar; for twelve fancy or yellow ground Carnations of dissimilar varieties; and for twelve distinct varieties of self yellow ground Picotees or fancies, these last-named being staged in groups of threes. He also won the 1st prizes in all the six classes for vases of Carnations of scheduled colours. The best six selfs, dissimilar, were shown by Mr. C. CHATWIN, Handsworth; 2nd, Mr. H. SKEELS; and the best six fancies or yellow grounds, dissimilar, by Mr. H. NORMANSELL, Mr. H. SKEELS being again 2nd.

Premier Blooms.—Bizarre Carnation "Master Fred," shown by Mr. W. H. PARTON; flake Carnation "Gordon Lewis," shown by Messrs. PEMBERTON & SONS; heavy-edge white ground Picotee "Cato," shown by Mr. R. G. RUDD; light or wire-edge white ground Picotee "Lavinia," shown by Messrs. PEMBERTON & SONS; heavy-edge yellow ground Picotee "Walter Heriot," shown by Mr. R. G. RUDD; light-edge yellow ground Picotee "Urania," shown by Mr. A. W. JONES; yellow ground fancy Carnation "Sam Weller," shown by Mr. A. W. JONES; self Carnation "Mrs. Eric Hambro," shown by Mr. A. W. JONES.

Medals were offered by the Birmingham Botanical and Horticultural Society for the exhibitors taking the largest number of prizes in the various sections Mr. W. H. PARTON being the most successful exhibitor, he was awarded

the large silver medal, and also the silver medal for single blooms. Mr. A. W. Jones secured the bronze medal. The silver medal offered to the most successful exhibitor in the smaller classes was awarded to Mr. R. G. Rudd.

HONORARY EXHIBITS.

The following awards were given for non-competitive displays of flowers:—

Silver Gilt Medals:—Messrs. Bakers, Wolverhampton, for a collection of climbing and other Roses; Messrs. Hewitt & Co., Solihull, for a collection of border flowers, Carnations, &c.; Mr. A. F. Dutton, Iver, Bucks., for American Tree Carnations; Messrs. Gunn & Sons, Olton, Birmingham, for hardy flowers, including some fine garden Phloxes.

Large Silver Medals:—Messrs. Simpson & Sons, Birmingham, for Sweet Peas, including several new varieties of merit; Messrs. Davis & Son, Yeovil, for tuberous-rooting Begonias; Mr. Wm. Sydenham, Tamworth, for a collection of hardy flowers and Carnations.

Silver Medals:—Messrs. James Randall & Sons, Shirley, Birmingham, for Tree Carnations; Mr. Robt. Sydenham, Birmingham, for Sweet Peas arranged in rustic table ornaments; Messrs. Bick Brothers, Olton, for hardy flowers; Messrs. Phillips & Taylor, Bracknell, Berks., for border Carnations; G. A. Kenrick, Esq., Edgbaston, Birmingham, for Campanula pyramidalis.

WEST DERBY HORTICULTURAL.

August 6.—The above Society held its Sixteenth Annual Exhibition of Flowers, Fruits, and Vegetables on the above date in the Rectory grounds. The show was one of the best held by the Society. In the principal Class, that for a group of plants arranged for effect, Mr. Geo. Osborne (gr. to Dr. Cooke), The Brook Private Asylum, carried off the premier honours, being closely followed by Mr. Bright (gr. Mr. Knowles). Although the season has been very dry and the nights cold, the exhibition of Vegetables were, on the whole, good. Mr. Chas. Young, Floral Nursery, arranged a table of Carnations. *G. O.*

GUILDFORD GARDENERS' MUTUAL IMPROVEMENT.

July 25.—The second annual summer show of the Guildford and District Gardeners' Mutual Improvement Association was held at Cross Lanes, the residence of the mayor (Alderman F. F. Smallpiece, J.P.), this year's president of the association, who had placed his grounds at their disposal. It is a non-competitive exhibition, instituted with a view of promoting an active interest among gardeners. Only members of the association can exhibit, and the number of entries had grown from 15 at last year's show to 66—a most gratifying improvement.

CHESTERFIELD ROSE AND HORTICULTURAL.

August 1.—The annual exhibition of this society was held in the Queen's Park, and proved an unqualified success. The class for 72 Roses attracted six competitors and resulted in a splendid show. Messrs. Perkins, Coventry, were placed 1st; 2nd, Messrs. Harkness & Co., Hitchin; 3rd, King's Acre Nursery Co., Hereford. In the class for 36 Roses Messrs. H. Drew & Co., Longworth, Berks, obtained 1st prize, the 2nd going to the Hereford firm. Tea Roses were shown in good condition, the prizes going to King's Acre Nursery Co., Messrs. Harkness & Co., and Messrs. H. Drew & Co., in the order named. Mr. J. Bacon was 1st for 4 vases of Roses, 2nd King's Acre Nursery Co. The best bouquet of Roses was shown by Messrs. R. W. Proctor & Sons.

The groups of plants arranged for effect to cover 200 square feet were this year circular in form. Mr. T. J. Nelson (gr. to A. T. H. Barnes, Esq.), Ashgate Chesterfield, put up a fine lot of plants arranged in the best style. Four groups were arranged in the class for a group of plants occupying an area of 100 feet of space; Dr. G. Booth, of Holywell House (gr. Mr. D. Money), gaining the 1st prize.

An attractive feature of the show was the competitive trade displays exhibited on 25 feet run of tabling at the side of the tent. Messrs. R. W. Proctor & Sons, the local firm, were successful with a fine exhibit of floral devices, &c.

MARKETS.

COVENT GARDEN, August 8.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday, by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate, not only from day to day, but occasionally several times in one day.—Ed.]

Remarks.—English Nectarines are scarce at 1 dozen. Peaches are a fairly good supply. English Green Flesh Melons are also scarce, and good samples are realising high prices. Trade generally is fair. *A. H. Rides, Covent Garden, August 8, 1906.*

POTATOS.

Lincolns, 70s. to 80s.; Bedfords, 60s. to 70s.; Kents, 80s. to 90s. *John Bath, 32 and 34, Wellington Street, Covent Garden.*

COVENT GARDEN FLOWER MARKET.

Very few growers were represented [illegible] morning, and those who had plants f[illegible] Sweet is still sending good plants of Ver[illegible] and other varieties; he has also some [illegible] cluding the variety Queen Alexandra [illegible] with a brisk sale. I have noted this var[illegible] growers' stands; the flowers are a pure w[illegible] journey they do not stand up well. Mr. W. [illegible] bringing good Ivy-leaved Pelargoniums, Galilee [illegible]

nally good for so late a period in the season. The same grower's Zonals are also good. And up to Saturday last he had good Mignonette. This plant is also well displayed by Mr. Mott, who still fills his stands well. Lantanas, in well-flowered plants, being very pretty. His Fuchsias are also good. Mr. F. Rochford has nice Fuchsias; Liliums in pots are good, and Rhodanthe is well flowered. Coreopsis from Mr. Lewington is first class. Campanula isophylla alba and C. Mayi are displayed by Mr. T. Childs, and by other growers. Palms are well supplied by Messrs. H. Low & Co., in various sizes; also by Mr. Bause. It appears likely that growers who are keeping up a succession will do better with their plants in the future, as many who started growing them because the seeds were cheap are now giving them up. I also learn that young plants are not so abundant on the Continent as they were a year or two ago. Ferns are abundant, though some of the large growers have empty stands. I noted some fine specimens of Nephrolepis exaltata from Mr. Denson; among all the new varieties of Nephrolepis, the above still remains a favourite. Asparagus plumosus, tenuissimus, and A. Sprengeri are marketed by Messrs. Whiteley, Ltd., in excellent condition.

CUT FLOWERS.

Owing to the excessive heat trade in cut flowers is very precarious—yesterday morning good white flowers were wanted. Eucharis and best white Roses were scarce late in the morning. Many of the Roses are now of indifferent quality—they are certainly offered at very low prices. Carnations are over plentiful, the American varieties, which are usually regarded as winter flowers only, are of as good quality now as at any time. An American grower whom I recently met expressed his surprise at seeing the fine blooms exhibited at the last meeting of the Royal Horticultural Society. Sweet Peas are still plentiful, but many are of very poor quality. Mr. P. Ladds still keeps up a good supply of Chrysanthemums; they are confined to the three varieties previously named. Gladiolus Brenchleyensis is very fine; there are also some good spikes of the choicer hybrid varieties, but these being cut with short stems do not sell readily. G. Colvillei "The Bride," is still very plentiful. Asters are abundant in white, pink, mauve and purple shades. Liliums in all the usual market sorts are good. Mr. Werring is bringing in Gypsophila paniculata flore pleno; this is equally as light and graceful as the old single form, almost as pure a white, and it remains in condition for a long time when cut. I find it comes quite pure white and is much prettier if given a little shade from the time the flowers begin to open. Scabiosa caucasica has been plentiful from several growers. Double White Stocks are good, and now that they are so much used for foundations for floral wreaths, &c., they are always in demand. Statices in several varieties are abundant. *A. H., Covent Garden, Wednesday, August 8, 1906.*

GARDENERS' DEBATING SOCIETY.

CROYDON & DISTRICT HORTICULTURAL.—

Greenwich Park was the rendezvous of this society for their evening outing on Wednesday the 1st inst., the attraction being the floral bedding, which is of a very fine standard of excellence. In all cases careful study has been given to blend colours together in effective display. In one bed was a fine collection of Cactaceous plants, some of the members being of great age. A feature is the correct labelling of the plants, which creates an excellent medium for information. A visit was also paid to the nursery. The old avenue of Chestnuts was planted somewhere about 1670. A walk through the noted Queen Charlotte's garden was taken, and following down to almost the foot of the hill at the Greenwich entrance a very interesting inspection was made of the tunnel, which, in its winding path, takes one under the hill to Blackheath.

Obituary.

F. W. MEYER.—We regret to record the death on Monday last of Mr. F. W. Meyer, of Exeter, who had been connected with the firm of Robert Veitch & Son for the last thirty years, for the most part of which time he has been their landscape gardener. A little over a month ago Mr. Meyer was taken ill whilst on a business journey in the neighbourhood of Taunton, but in two or three weeks recovered sufficiently to resume work. He returned to Exeter on Saturday last, and, after a day or two's illness, suddenly died of heart failure. Locally, through attending the leading flower shows in the West of England, and taking occasional journeys for Messrs. Veitch, he was well known and much esteemed. As landscape gardener he carried out important works in laying out many years ago the grounds at Bystock, near Exmouth, the public parks at Poole, Devonport, Wellington, and recently at Sherborne. Under his care, exclusive landscape designs were completed for the late Mr. Fisher, of Newton Abbot, Lord Lilford, at Lilford Hall, Mr. Paris Singer, at Paignton, and many others in different parts of England. The public grounds at Exeter were a few years ago greatly improved under designs prepared by Mr. Meyer, and at the time of his death he was in the midst of the details of his plan, which had been accepted, for laying out a rockery and Alpine garden for the Royal Horticultural Society at their new place at Wisley, the Society having entrusted the scheme to Messrs. Robert Veitch & Son. Mr. Meyer was a frequent contributor to the horticultural Press of England and of his native country, Germany.

ANSWERS TO CORRESPONDENTS

CARNATIONS: *A. M.* There are many as good, and some better.

COTTON SEEDS: *Clifton.* Seeds of the Cotton plant need to be germinated in a warm greenhouse, as the Gossypium is a tropical plant, and very tender. Peach "stones," as they are termed, may be planted out of doors, and the seeds will germinate freely there, the plant being perfectly hardy.

EXHIBITING VEGETABLES: *Correspondent.* The usual plan of exhibiting vegetables adopted by the best exhibitors is to construct a staging similar to that shown in fig. 46. This, it will be seen, is in shape much like an office desk, with the usual raised portion (A) at the back (the diagram does not show this back as high as it is usually seen, but the exhibitor can modify the height as required). The back can be made of light boarding, and in front is a square portion (B), upon which the boards forming (C) rest, and slope to the front. The boards forming the

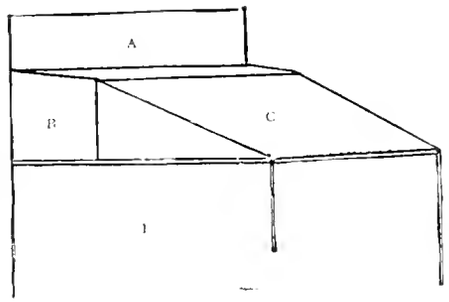

FIG. 45.—STAND FOR EXHIBITING VEGETABLES.

platform (C) often meet (B) about three-parts up, and not quite to the top as is shown in our diagram. Against (A) are usually placed Cauliflowers, Cabbage, or Broccoli in pyramids, with Marrows, Cucumbers, and such-like large vegetables on (E). The space (C) is usually reserved for dishes containing Tomatos, Mushrooms, Capsicums, Potatos, &c., with the larger subjects at the back. A bedding of Parsley is placed over the whole staging before arranging the vegetables. The table (E) is represented in the sketch by the three bottom vertical lines in the diagram.

GOOSEBERRY SHOOT: *Scott Crescent.* The "blight" on the Gooseberry shoots are the cast skins of one of the Aphides, probably Myzus ribis, but as there were not any living or dead insects on the shoots or leaves we cannot say with certainty what the species is. If there are any living aphides on the bushes you should spray them with a solution of paraffin emulsion, or soft soap and quassia extract. We could not find any trace of insects or fungi on the Apple leaves, but they are of a very poor colour.

GLADIOLUS: *H. S.* There is no disease present in the bulbs that could be attributed to fungi or insects, and the failure is in some way due to treatment, which can only be determined on the spot.

GRAPES: *Small Loaf and A. B.* The injury is known as "white rot"; remove all diseased shoots and spray the plants with a rose-red solution of Condy's fluid. When the plant is resting in winter drench every part, also the ground with a solution consisting of 1 pound of sulphate of copper in 25 gallons of water.

HEAD GARDENERS' POSITIONS: *D. F.* The publication of your letter would do no good. You should join the British Gardeners' Association, which is the proper body to discuss this and similar matters.

INVESTMENT OF CAPITAL: *E. H.* We are reluctant to give any advice on such a subject, but it has been proved in numberless instances that to embark with a small capital in a business you do not understand is to court disaster. You should be content to work under others in order to acquire the technical and practical knowledge that is essential.

LILAC FORCING: *Secretary.* We cannot undertake to say that Lilac forcing would be a profitable undertaking for any particular market gardener, because so much would depend upon how the business was managed. It is, however, we believe, a fact that growers do pursue the practice with profit, less or more according to circumstances. The wholesale prices obtained in Covent Garden market are recorded throughout the season in the market returns published in these pages.

MARKET GARDENING: *J. A. W.* A book by Mr. R. L. Castle has recently been published on this subject by Mr. John Lane, Vigo Street, London, W.

NAMES OF FRUITS: *J. D.* We do not recognise the Gooseberry.—*R. J.* (next week).

NAMES OF PLANTS: *Cestrian.* Venus' Looking Glass (Specularia Speculum.)—*G. Broadfoot.* Prunus serotina.—*A. L.* (*Bougival*). Campanula versicolor.—*C. E. A.* 1, Lychnis chalcedonica; 2, Funckia ovata; 3, Aconitum variegatum; 4, Lupinus polyphyllus albus; 5, Galega officinalis; 6, Lysimachia thyrsiflora.—*Gladiolus.* Send to some grower of these plants. The shrub is Carpenteria californica, lately figured in the *Chronicle.*—*Old Subscriber.* The larger flower is Odontoglossum citrosmum; the spray Oncidium incurvum.—*A. Y. L.* 1, Liparis purpurea; 2, Pleurothallis rubens.—*G. N.* Trichopilia tortilis.—*L. Hawkins.* 1, Lonicera capritolium; 2, Veronica salicifolia; 3, Erica cinerea alba; 4, Phacelia congesta; 5, Spiræa Ulmaria fl. pl.; 6, Senecio Jacobæa.—*A. M.* 1, Epipactis latifolia; 2, Senecio Jacobæa; 3, Dipsacus sylvestris; 4, Lythrum Salicaria.—*A. P. N.* Allium (next week); Spiræa callosa.—*W. F.* The early stage of Phallus impudicus, one of the most stinking fungi known. We advise you not to eat it.—*T. O.* 1, Sanguisorba officinalis; 2, Coreopsis grandiflora; 3 (next week); 4, Tanacetum vulgare; 5, Jasminum officinale; 6, Inula Helenium.

NOTICE TO LEAVE: *M. W.* We think under the circumstances the gardener is entitled to a month's notice, but in this, as in all other such cases, there should have been an agreement at the time of making the engagement.

ONIONS: *G. K.* The maggots present are undoubtedly those of the Onion-fly. The Cauliflower roots are eaten by wire-worms.

ORCHID COMPOST: *A. v. d. G.* The potting material in which your Orchids are growing is destroyed by the grubs of a small fly, one of the Mycetophilidæ, or "Fungus flies," so called from the grubs of many species living in fungi—the family contains a very large number of species. The flies might be killed by fumigation, and the grubs by soaking the potting material with lime-water, but whether the lime-water would have a prejudicial effect on the roots of the plants would have to be determined.

PLUM TREE: *F. J. Myers.* The trees are infested by the caterpillars of the "Vapourer Moth" (Orgyia antiqua). Spraying with soft soap emulsions is not of much use in the case of these hairy caterpillars, as the insecticide does not reach them so as to choke up their breathing pores, but they would probably be poisoned if the leaves were sprayed with "Paris green" or arsenate of lead. The females are wingless, and when they leave the cocoons do not wander far away, but as often as not deposit their eggs on the surface of the cocoons which they have just left. These cocoons should be searched for and destroyed.

ROSE AND PELARGONIUM: *F. J.* Kindly send specimens, and we will examine them.

STRAWBERRY PLANT: *Glasgow.* The injury is caused by a fungus Sphærella fragariæ having attacked the fruiting stem. See reply to *E. P. C.*, in our issue for June 2.

TESTIMONIAL: *Enquirer.* Your former employer is not obliged to give you, or any one else, a testimonial on your behalf; but if he should do so it must be strictly accurate.

TOMATOS: *Ignoramus.* Your plants are badly affected with the fungus Cladosporium fulvum. We fear you can do nothing this year. Next year try spraying with Bordeaux mixture, and cleanse the house thoroughly.

VINE LEAVES: *W. G.* The spots are minute scale insects, Lecanium, and can readily be removed by the use of a sponge and soft soap

ILLUSTRATIONS.

GUNNERSBURY PARK.

IN our last issue we published some descriptive notes and illustrations of Gunnersbury House and its gardens, one of the places to which Mr. Leopold de Rothschild invited the members of the Hybridisation Conference. The Gunnersbury Park estate adjoins this one, but is much more extensive. The residence, in two rooms of which the members were entertained at luncheon, is a handsome specimen of the Tuscan order, its south front being almost in a line with that of Gunnersbury House. The Gunnersbury Park residence was built by one Alexander Copeland, from whom it was purchased by the Baron Rothschild of that day. It is only in recent years that Mr. Leopold de Rothschild purchased Gunnersbury House, owing to its nearness to the Park. Although it is situated but a few minutes' walk from Kew Bridge, and less than a mile from the noisome slums of Brentford and the unattractive purlieus of Acton, the Park estate consists of about 200 acres of land, and in walking through the grounds the visitor could easily imagine himself to be very far away from town, for the trees screen any object beyond the boundary of the park that would otherwise obtrude itself into the view. It is only too true that the fine old trees at Gunnersbury are failing each year, and that many of the grand Lebanon Cedars have perished during the last quarter of a century. This is particularly noticeable by the lake, which is shown at Fig. 48. Several of the Cedars to be seen in the illustration on either side of the "Temple" have had to be removed during the past two years. Having said this much, however, we may also say that the grandest feature of the park still consists in its noble trees. No one familiar with Gunnersbury would expect to see so many aged Cedars as there are still alive, and some of the deciduous trees, especially the Elms, are magnificent specimens. Mr. de Rothschild rightly sets great store upon these, and everything that is possible is done to fight the conditions that would be likely to hasten their decay. We suppose that it is a generally accepted fact that in urban districts, at least, more large trees die from the effects of drought than from any other cause, and it is also necessary to remember that after a certain age a tree is less able to extend its root system into fresh soil, consequently it becomes more necessary than ever to help it as far as possible by applying rich top-dressings over the principal roots.

All this is done with scrupulous care at Gunnersbury, and the head gardener, Mr. George Reynolds, who has been in these gardens for more than 30 years, superintends the chaining and shoring up of great branches that might otherwise be broken off by high winds or by heavy snowstorms.

The Ponds.

In the illustration we have already referred to, one of the three ponds can be seen, and as it is used in winter time for skating and other games, no water lilies are cultivated in the water. But there are two other ponds, and one of these is shown at Fig. 51. The visitor at this date would hardly suppose that it is on the site of an old clay pit, and that where the tower can be seen there used to stand an ordinary brick kiln! Yet such is the case, and now the effect is both park-like and picturesque, such is the work of the landscape gardener and "time." The third pond is on the other side of the grounds, and very near to Gunnersbury House gardens. It is in this pond that the Water Lilies are cultivated, and at the present time they are in most vigorous leaf and blossom.

The Fruit and Plant Houses.

On a recent visit we commenced an inspection of the gardens from the gardener's residence, and we were fortunate in having Mr. Reynolds for our guide. Immediately at one's right hand is the long Peach and Nectarine case, which is 360ft. in length and heated with hot water pipes. The trees are in excellent condition, but most of them have yielded their crop of fruit for the present season. The three latest varieties, however, were still laden with fruits hardly ripe. These were Nectarine Peach, Sea Eagle and Princess of Wales. Next to this case (in which the trees are grown against the wall and are protected with a glass front) is the old Rosary. This house has been altered to provide suitable conditions for the Odontoglossums. On the site where the centre bed used to be a tank has been placed, and over the tank of water is the stage supporting the Odontoglossums. From the present condition of the plants it is evident that they will thrive well in their new house. Suspended in baskets we noticed a good plant of Asparagus Sprengeri variegatus, which requires some amount of humoring to make a big specimen, and several plants of A. myriocladus. This latter species is very plumose and very decorative; the young growths will certainly extend seven feet high or more. In close proximity there are two long span-roofed houses, each of which is divided into two or more divisions. In these we noticed considerable batches of Lobelia tenuior, Celosias, Gloriosa superba, G. Rothschildiana, Allamanda Hendersoni (affording an unusually grand display of colour), A. Williamsi, etc. There being many plants of Gloriosa superba in flower, it was interesting to notice how much the species varied in colour in the individual plants. Some were very much richer than others, and richer than any we remember to have seen. A high-roofed house close by contained a good batch of Eucharis grandiflora, the pretty but seldom seen Griffinias, Amasonia punicea, Ixoras in considerable numbers in full flower, Acalypha hispida (in 10-inch pots), and Vanda teres. This shy blooming Vanda flowers every season here and has continued to do so for a long period. As Mr. Reynolds remarked to us, the atmosphere of the house seems to suit them perfectly. There are always decaying leaves in the house, and these serve to keep the atmosphere moist. In winter, when the plants are at rest, the roots are kept dry, and the amount of moisture necessary to keep the pseudo-bulbs from shrivelling is supplied from the atmosphere to the pseudo-bulbs themselves. But if at any time this proves to be insufficient, water is afforded to the roots at once, for if much shrivelling were permitted to take place the result would be bad. The variety Miss Joachim was still in flower.

The tree Carnations are cultivated to give their best display in September and October, but the variety Duchess of Portland was already opening some flowers, and another good pink variety, largely cultivated at Gunnersbury, is Mrs. Leopold de Rothschild. The Cattleyas in the next division looked well, and C. labiata will soon be throwing up flowers.

The Vineries at Gunnersbury Park are of large dimensions, and each vine is cultivated to produce a liberal crop of fruit. The first we entered contained four divisions. In two of these the vines have been renewed by Mr. Reynolds, and in the other two they have not. The Muscats of Alexandria have been planted for 30 years, at least, yet are bearing excellent bunches, as is also Chasselas Napoleon. The "great" vinery has a span roof and contains chiefly black Hamburgh Grapes.

In few, if any, private gardens are Figs cultivated in such large quantities as they are in both of the Gunnersbury gardens. The Fig house at the "Park" is narrow, long, and divided into three divisions. The trees are planted against the back wall, upon which they are first trained, and then trained along the roof towards the front of the house. The varieties consist of Brown Turkey, Negro Largo, and White Marseilles. The first division is started into growth each year in

November, and the three divisions furnish ripe fruits from April until October. Pot trees are grown in other houses to increase the supply late in summer and in autumn.

We had occasion to refer so fully last week to the pot fruit trees under Mr. Hudson's care, that it will not be necessary to write much on this subject now. Mr. Reynolds has a splendid lot, in full fruit, of Plums, Nectarines, and Peaches, and the crops are exceedingly liberal. On one quite ordinary specimen of Sea Eagle Peach (in a 10-inch pot) we counted ten heavy fruits.

Melons are grown in large numbers, the varieties Princeheim and Gunton Scarlet being among those most favoured. In addition to Melons of the ordinary type, both Cantaloupe and Syrian Melons are also cultivated, as they meet with much appreciation.

Some of our readers may remember the illustration which appeared in these pages on April 10th, 1873 (p. 544), showing the pair of very large tree Ferns (Dicksonia antarctica) growing at Gunnersbury. They had been sent to Baroness Rothschild by Governor Ducane, from Mount Wellington, Tasmania, and weighed 23 cwt. each. One of these is still alive and growing well, but the other was killed owing to a workman accidentally upsetting a can of paint over the crown!

Other smaller specimens have been purchased since that time.

There are still several features in the open air at Gunnersbury deserving remark. One of these is the large batch of Crinum Powellii at one end of one of the glass houses, which are in full flower at the present time; another is an excellent specimen of the Exmouth variety of Magnolia grandiflora now coming into flower; a third the standard, and other large plants of Pelargoniums on the terrace and in other suitable situations; and a fourth the flower garden in which each bed represents a basket. All the beds are filled with Pelargoniums, either pink or white exclusively, and the "handle" is of Roses, Clematis, &c.

We noticed a single-flowered, rich scarlet-coloured zonal Pelargonium, named Paul Crampnell, that was exceedingly effective. Against the exterior of one of the houses such old varieties of Fuchsias as Venus de Medici, Rose of Castile, &c., were trained 15 feet high. Chrysanthemums are grown in very large numbers, and many other plants to which we cannot refer in detail.

Mr. Reynolds, whose portrait we have pleasure in presenting (p. 125), is to be congratulated on the excellent condition of everything in this remarkable garden.

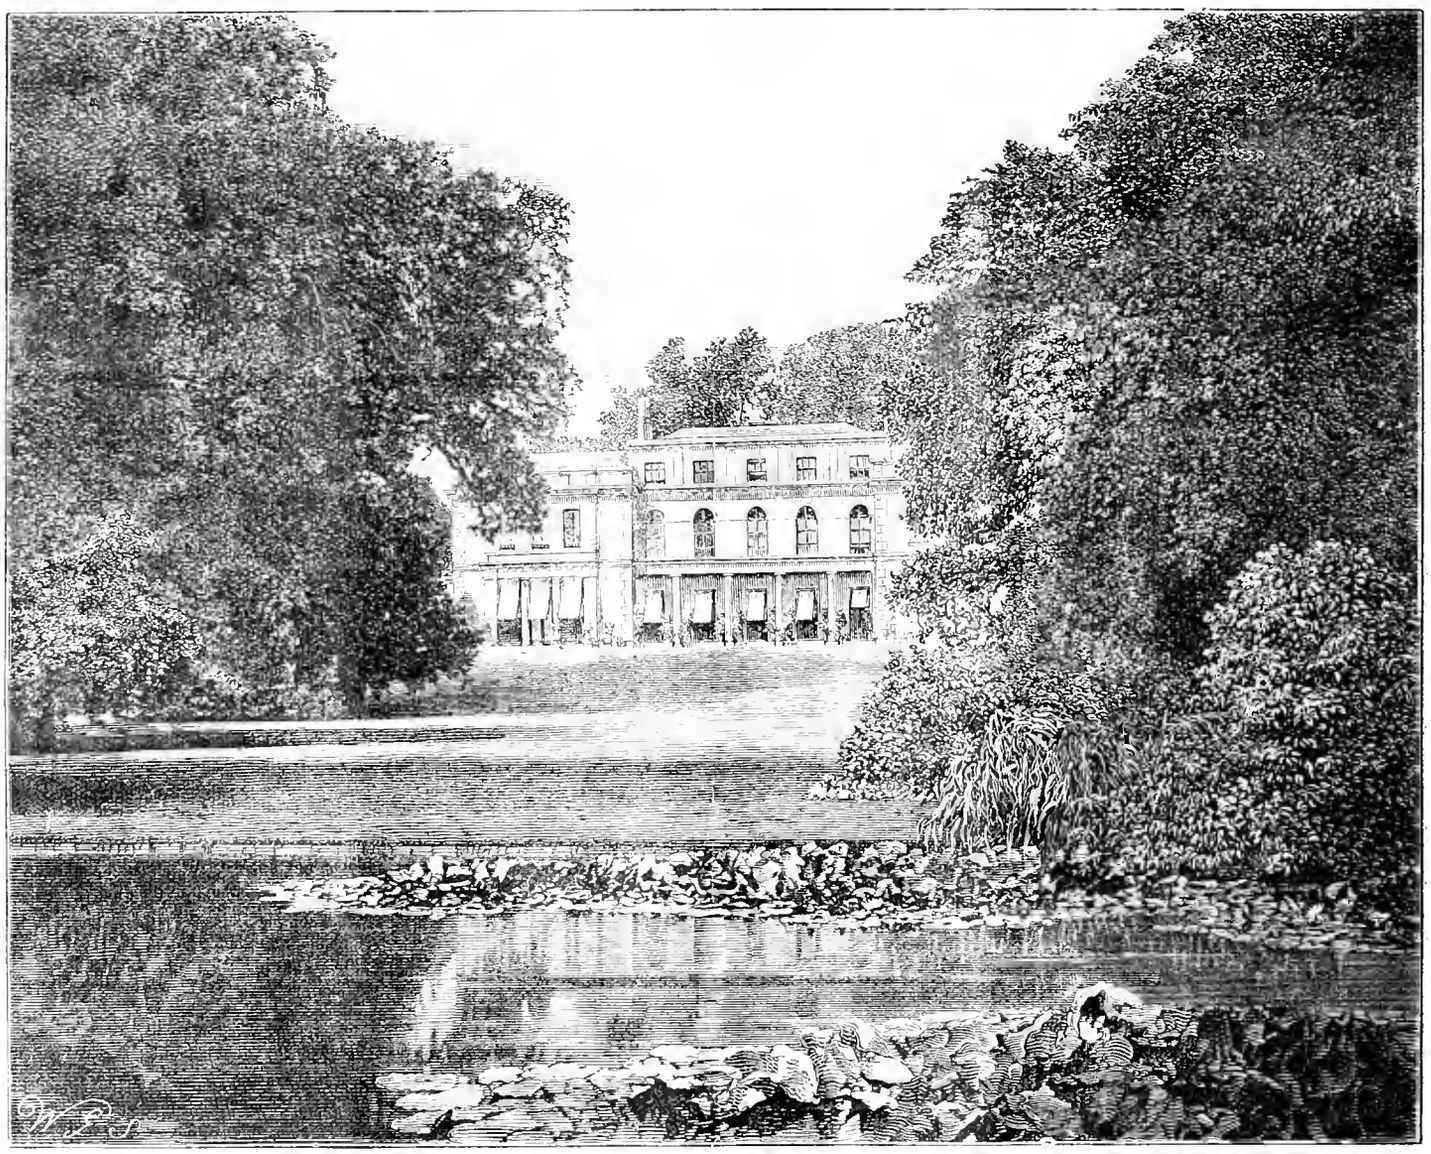

FIG. 47.—GUNNERSBURY PARK, ACTON, THE RESIDENCE OF LEOPOLD DE ROTHSCHILD, ESQ.

NEW OR NOTEWORTHY PLANTS.

HAPLOCARPHA SCAPOSA, HARVEY.*

HAPLOCARPHA is a small genus of Compositæ, closely related to and much resembling the acaulescent species of Venidium and Arctotis, and comprises five species, all natives of South Africa; only two of them have yet been introduced into cultivation, viz., H. Leichtlinii, which I described in the *Gardeners' Chronicle*, 1883, vol. 19, p. 78, and the present species (see p. 124, fig. 49). As H. scaposa is the commonest and most widely distributed of all the species, it is somewhat remarkable that its introduction has been so tardy, for so far as I can discover it was first introduced about 12 years ago, having flowered in Cambridge Botanic Garden in November, 1894, and I have no knowledge of its having previously been figured. It was originally discovered in 1813 by the celebrated traveller Burchell, on Bruintjes Hoogte, a mountain in Somerset Division, and has since been gathered by many collectors. It seems to be confined to the eastern part of South Africa, ranging eastwards from Uitenhage and Somerset Divisions, through Tembuland and Griqualand East to Natal, and northwards through the Orange River Colony, Transvaal, Rhodesia and Nyassaland

* HAPLOCARPHA SCAPOSA, HARVEY. *Flora Capensis*, vol. 3, p. 465. H. Thunbergii, *DC. Prod.*, vol. 6, p. 491, not of Lessing.

as far as Fwambo at the south end of Lake Tanganyika.

The specimen of H. scaposa here figured (fig. 49, p. 124), was kindly contributed by Mr. W. E. Gumbleton, of Queenstown, Co. Cork, with whom it is now in flower; a specimen has also been sent to Kew by Mr. R. A. Beamish, of Ashbourne. It is a stemless, herbaceous perennial, which is probably not hardy enough to withstand our winters. The rootstock is short and branching, sometimes with a tendency to produce short creeping stolons. The leaves are all radical, 3-9 inches long and 1-3 inches wide, varying from lanceolate to elliptic, tapering into the petiole at the base, obtuse at the apex, more or less obtusely toothed, or sometimes nearly entire, five to seven-nerved, green above and with a white felted tomentum beneath. The peduncles in wild specimens are usually 9-18 inches long, but under cultivation become 2-2½ feet long, they are white-tomentose and leafless. The flower heads are radiate, 1½-2½ inches in diameter, clear yellow, woolly on the involucre. The achenes have a tuft of long hairs at their base and are crowned with numerous long, narrow, taper-pointed pappus scales. It is by the character of the achenes that the genus Haplocarpha is distinguished from Arctotis: in the former they are solid, whilst in Arctotis they have two cavities on one side. *N. E. Brown.*

REMARKS ON THE CONDITION OF THE FRUIT CROPS.

(See Tables and Summaries, ante, pp. 64-70.)

(Continued from page 106.)

5.—SOUTHERN COUNTIES.

Surrey.—Our soil is sandy and very sterile. Frost destroyed all the Plums and Nuts when in blossom, and greatly affected the crops of Apples, Pears, Currants, and early Strawberries. In addition, the Pear midge has been greatly destructive, destroying the whole crop of Pears in some cases. *C. J. Salter, Woodhatch Lodge Gardens, Reigate.*

—— The primary cause of the short crops of Pears and Plums was the severe frosts of April. Had the spring been less cold, we might have seen a perfect glut of the fruits named. *Alex. Dean, 62, Richmond Road, Kingston-on-Thames.*

—— The general cause for failure in the fruit crops was frost in the late spring. The soil here is a light, sandy, almost gravelly, loam. *Geo. Kent, Norbury Park, Dorking.*

Sussex.—Our soil varies from light to clayey loam, the sub-soil being sandstone impregnated with iron. All kinds of fruit trees had abundance of blossom, promising bountiful crops, but the severe frosts ruined the Plums, Pears, and Black Currants while they were in bloom. *Alex. Reid, Possingworth Gardens, Cross in Hand.*

—— The late spring frosts and the cold east winds adversely affected the fruit crops in this district. The nature of our soil is flinty-loam on a sub-soil of chalk. *W. H. Smith, West Dean Park Gardens, Chichester.*

—— The crops of Apples, Pears, Plums, and Apricots were more or less ruined by the cold, bleak winds and severe frosts of April and May. Our soil is a good, retentive loam. *G. Grigg, Ashburnham Place Gardens, Battle.*

—— The late spring frosts and the cold winds caused much damage to all stone fruits. Some varieties of Strawberries, including Royal Sovereign and President, also suffered severely, but Monarch and Sensation carried good crops. Crops of Raspberries and Gooseberries were very heavy, the fruits being of good quality. Our soil is a very stiff clayey loam, overlying a sub-soil of yellow clay. *W. Langridge, Ote Hall Gardens, Burgess Hill.*

—— The frost on June 2 caused Cherries and Pears to drop largely, favoured the attacks of a terrible pest of Black Aphis, and created spot on Apples and Cherries. The soil of these gardens is a mixture of poor loamy clay and sand, and one that requires a lot of fe[illegible] *W. H. [illegible], Leonardslee Gardens, Horsham.*

—— Late frosts and continued east winds, coupled with a continuation of cloudy weather,

Fig. 48.—Gunnersbury Park, Acton.

(For text see page 121.)

mostly affected the fruit crops in this district. Our soil is of a light nature, overlying a sub-soil of chalk. *E. Burbury, Castle Gardens, Arundel.*

—— The late spring frosts and the cold east winds mostly affected the fruit crops in this district. The sub-soil is sandy rock. *H. C. Prinsep, Buxted Park, Uckfield.*

WILTSHIRE.—A heavy shower of rain, followed by 12° of frost on April 29 completely ruined the Cherry and the Plum crops in this district. Pears also suffered from these causes, and, in addition, the Pear midge has been very troublesome. Our soil is rather heavy, and fairly deep, with a stiff, yellow, clayey sub-soil. *H. Gandy, Longleat Gardens, Warminster.*

—— The severe frosts during the time the young fruits were setting was ruinous to the fruit crops, there being as much as 10° and 12° of frost during the time the Pear trees were in bloom. Fortunately, Apples escaped much injury. The soil in this district is a sandy loam, with, in most parts, a sub-soil of stiff clay. All young fruit trees require a flag stone or concrete bottom to prevent the tap root going downwards. *John Bannerman, Lackham Gardens, Lacock.*

—— Long-continued frosts and cold winds in April and May, and severe hail storms on June 16 and 23 were most injurious to all kinds of fruits. The soil is a chalky marl, overlying a sub-soil of gravel. *Thomas Challis, The Gardens, Wilton House.*

—— The prevalence of late spring frosts and cold easterly winds, bringing blight in their train, have had disastrous effects on the fruit crops of this district. The soil consists of brash limestone. *W. Tinley, Malmesbury.*

—— The weather has been very favourable to most fruits, and crops, on the whole, are good, with the exception of Pears, which, when in bloom, suffered considerably from the east winds. The soil of this district is mostly a friable loam, with either a chalky or a gravelly sub-soil. *S. H. Tucker, Longford Castle Gardens, Salisbury.*

7.—ENGLAND, N.W.

CUMBERLAND.—Pears and Plums are a failure here, owing to a wet and sunless May. The soil is of medium quality, resting on clay. *Thomas Tunstall, Carleton Hill, Penrith.*

LANCASHIRE.—A cold week culminating in 15° of frost when Pears and Plums were in flower ruined our fruit crops, and is the cause of the worst season for fruit in 25 years. Only twice before have we had anything approaching such ruin, for we have been fortunate in having crops when others have been without. Our sub-soil is clay, but by cultivation we have a couple of feet of good soil that will grow most vegetables well. *Wm. P. Roberts, The Gardens, Cuerden Hall, Preston.*

—— Our short crops are attributable to the cold, uncongenial weather in spring time when the trees were in bloom, and to the severe drought during July and August, which still further reduced the crops where it was not possible to afford water. The soil is a heavy loam on clay. *E. F. Hazelton, Knowsley Gardens, Prescot.*

—— After an abundant show of blossom, the fruit crops are very poor, excepting those of small fruits. Late spring frosts, with cold winds, did extensive damage. Swarms of insect pests followed the cold winds, and all the young leaves, especially those of Apples, were either eaten or badly disfigured. Our soil is a very light loam, with a poor, gravelly sub-soil, some parts being very near a rock base. *Wm. Ashton, Wrightington Hall Gardens, Wigan.*

—— The fruit crops in this district were badly affected by a succession of frosts during the month of April, and by a prevalence of cold easterly winds throughout the month of May. Our soil is moderately heavy; the sub-soil consists of red sandstone formation. *Benjamin Cromwell, Clewley Gardens, Allerton, Liverpool.*

—— Late spring frosts badly affected the fruit crops in this district. Bullfinches did much damage to fruit buds in the early spring. Strawberries, Gooseberries, Raspberries, and Red Currants are all good crops. The soil is a heavy loam, and in some parts clay. *Thomas Wyton, The Gardens, Abbeystead, Lancaster.*

—— Cold north-east winds, followed by blight, when the blossom was setting are the causes of our indifferent crops of fruits. The soil consists of a light limestone, overlying a sub-soil of rotten rock and clayey "sammel." *G. H. Tansley, Witherslack Hall Gardens, Grange-over-Sands.*

—— Late spring frosts appearing when Plums and Pears were in bloom, proved disastrous, especially to Plums and Damsons, of which fruits we have practically none. Our soil is a dark, sandy loam, on a sub-soil of white sand. *Ben Ashton, Latham House Gardens, Ormskirk.*

FIG. 49.—HAPLOCARPHA SCAPOSA: FLOWERS CLEAR YELLOW, THE INVOLUCRE BEING WOOLLY. (For text see page 122.)

Westmoreland.—The severe frosts in spring time, and the prevalence of cold east winds during May were the causes of failure in our fruit crops. The soil is of a heavy nature, and rests on a clay sub-soil. *F. Clarke, Lowther Castle Gardens, Penrith.*

—— Spring frosts and bullfinches ruined a promising crop of all fruits. Our soil is gravelly and thin. *W. A. Miller, Underley, Kirkby Lonsdale.*

—— In this district the failure of the fruit crops was due to the prevalence of cold, drying winds during the latter part of April and of early May, and, to a great extent, to the continued frosty nights of May. The soil is principally limestone. *Wm. Gibson, Levens Hall, Milnthorpe.*

—— The commencement of the season gave promise of exceptional crops of all fruits, but expectations have not been realised, owing to a wet and cold May. This is especially disappointing as we were free from severe late frosts. The soil varies from a stiff, heavy loam to a light, sandy soil, overlying a sub-soil of clay and gravel. *James Coupland, Brougham Hall Gardens, Penrith.*

6.—ENGLAND, S.W.

Cornwall.—The Apple crop was adversely affected in the spring by late frosts and the Codlin moth. Trees on walls also suffered, especially those of Peaches and Nectarines, and in many places the trees were completely killed. Plums in the large orchards in this neighbourhood are a failure, and many of these trees have also been killed. The general fruit crops are very disappointing after the great promise in early spring. Our soil is an adhesive loam on clay. *Wm. Sangwin, Trelissick Gardens, Truro.*

Devonshire.—The late spring frosts did considerable damage generally among the fruit crops. In the neighbourhood of Sowton, near Exeter, a severe hailstorm also did much injury. The "silver-leaf" disease has appeared in this district, and is spreading among Plums. The soil is good; much of it is heavy clay, but in the Plum-growing district it is generally a sandy loam. *Andrew Hope, 38, Prospect Park, Exeter.*

—— A thick mist and fog from the sea during the last seven days of May were very harmful to the fruit crops generally. Trees which had their fruit set previous to the fog are carrying heavy crops, but much of the blossom on the later sorts was destroyed. The soil is of a very light nature, and rests on the shaly Devon waterstone. *George Baker, Membland, Newton Ferrers, Plymouth.*

—— I cannot account for the poor crops of Peaches and Nectarines, for the blossom on these trees was abundant, and the set appeared good, but the fruits failed to swell, except those on south walls. As the majority of our trees occupy an eastern aspect, I imagine the trouble was the east winds during April and the early part of May. Boisterous winds from the north-west are answerable for many Apple trees in the district being quite fruitless. Our soil is a deep loam, inclined to sandy, with a red sandstone sub-soil. *James Mayne, The Gardens, Bicton, Budleigh Salterton.*

—— Plums and Damsons showed a paucity of blossom, but Apples carried an abundance of flowers. Cold, harsh winds, however, prevailed, while the last-named trees were in bloom, and this, together with the advent of wet frosts later, when fruits were just "set," caused failure. Strawberries have been a poor crop, as the rain came too late to benefit them. The soil here is a heavy loam, partly on sand and partly on clay. *T. H. Slade, The Gardens, Poltimore Park, Exeter.*

—— The late May frost and the continuation of cold nights in spring time are the causes of a poor fruit season. Our soil is a stiff loam on a clay bottom. *Thos. Seward, Tattram Gardens, Plympton.*

Gloucestershire. The frost in April and a continuation of east winds ruined the fruit crop here. Our soil is a stiff loam with blue lias clay as a sub-soil. The garden lies low, and catches the late spring frosts badly. We had 7° and 8° frost for several nights in early spring, and 10° on April 27. *Wm. Keen, Bowden Hall Gardens, nr. Gloucester.*

—— The dearth of Plums and the scarcity of Gooseberries and Cherries in these gardens I attribute to frost in April. Our Apple trees were badly infested with Aphis after the blooming period. There was a wealth of blossom, and I quite expected an over-average crop, but was disappointed. Our soil is a friable to clayey loam, overlying the old red sandstone. *John Banting, Tortworth Gardens, Falfield.*

—— All fruit trees gave promise early of good crops, but the frost on April 27—we registered 14°—ruined our Pears and Plums and that part of the Gooseberry crop on the outside of the bushes. We have the smallest crop of stone fruits of several seasons. *W. H. Berry, Highnam Court Gardens.*

—— The continuous cold winds and frosty nights of April ruined the Plum and Pear blossom, and quite spoilt these crops. Peaches and

Mr. George Reynolds, gardener at Gunnersbury Park.
(See page 121.)

Nectarines, where not well protected, also suffered badly. Apples bloomed rather later than is usual, and thus escaped the frosts. Our top soil is a light loam, the sub-soil being limestone brash. *William Nash, Badminton Gardens, Chippenham.*

—— Apples showed an abundance of blossom, but did not set well. Pears are a fair crop, but Plum trees have scarcely any fruits. All bush fruits are carrying good crops, especially Black Currants. Strawberries promised an enormous crop, but the fruits damped badly while colouring, owing to the very heavy rainfall during the last week in June. Our soil is a stiff loam on a sub-soil of clay. *W. Daffurn, Elm tree House Gardens, Tilbury.*

—— The Apple crop in this district is above the average. Pears on walls are a fair crop, but the disastrous frosts of April 20 and 30 and May 1 and 2 ruined both Pear and Plum blossoms on orchard trees. The crop of Cherries on walls is light. Peaches, Nectarines, and Apricots are a fair crop. Gooseberries are good, but Red and Black Currants are poor, and the bushes are much blighted. Raspberries and Strawberries are a good crop, and the fruits are of good flavour. The soil in this garden is a loam, resting on limestone. *F. C. Walton, Stanley Park Gardens, Stroud.*

—— Pear trees were laden with blossom, and escaped the late spring frosts, but the Pear midge attacked the best dessert kinds, and the greater number of fruits had to be hand-picked and burned. Apples are abundant on all trees, and require liberal thinning. Plums on wall trees that were protected are an average crop, but Plum trees in the open are carrying poor crops, owing to frosts destroying the fruit buds. Gooseberries are scarce; the bloom was damaged by frost. Other bush fruits are all good. The Strawberry crop is under the average, especially that of Royal Sovereign, which was badly attacked by mildew. Givon's Late Prolific carried a good crop of fruits. *A. Chapman, Westonbirt, Tetbury.*

—— The soil here is strong loam on clay. The severe frosts in April destroyed the crops of Peaches, Nectarines, Apricots, Cherries, Plums, Pears, Currants, and Gooseberries, and checked the growth of the trees, especially those of Peaches and Nectarines. *Alfred E. T. Rogers, The Gardens, Sudeley Castle, Winchcombe.*

Herefordshire.—On April 26 we experienced a heavy fall of snow, followed by 10° of frost. This ruined the bush fruits, Pears, and Plums, and considerably thinned the fruits on two long walls of Peaches and Nectarines, although they were well protected by half-inch mesh nets and by coping boards. Our soil is a good heavy loam resting on limestone. *George Mullins, Arthur Castle Gardens, Ledbury.*

—— Pears, Plums, Cherries, and small fruits are all a failure owing to sharp frosts when the trees were in flower. One or two nights we registered as much as 10° frost. *C. Smith, Barton Court Gardens, Colwall, Malvern.*

Monmouthshire.—Frost and the very cold nights during the time the Plum trees were in flower caused the failure of these fruits in this district. We are also greatly troubled with insect pests. Some standard trees of Apples are infested with red spider, which it seems impossible to eradicate. The soil here is a very cold, tenacious loam on a heavy clay, which rests on the old red sandstone. *W. F. Woods, Llanfrechfa Grange Gardens, Caerleon.*

—— I consider the general scarcity of Plums and some other fruits due to the low temperatures and sunless weather that prevailed during the blossoming period. The wind came from the north or east, and this caused more damage than did frosts. The soil here is a heavy clayey loam, resting on marl, or clay, and the nature of the weather during spring and summer has consequently greater influence upon the growth of trees than is usually the case. *T. Coomber, The Hendre Gardens.*

—— Our crops were spoiled by the dry easterly winds and sharp frosts during the latter part of April and up to the middle of May. Nearly all our fruit trees present a very stunted appearance for the time of year. Notwithstanding the long spells of easterly winds and sharp frosts during the latter part of April and up to the middle of May, Apples and Pears are a fair average crop in this neighbourhood. But in most cases stone fruits are a total failure, the only exceptions being where the trees are in a sheltered position, or where they received temporary protection during their flowering period. The soil here is a strong, tenacious loam overlying boulder clay. *Henry Townsend, Maindiff Court Gardens, Abergavenny.*

—— The Apple crop at one time promised to be a record one, but later it became very badly attacked by blight, more especially on trees growing in grass orchards. Pears are exceptionally clean and healthy. Cherries and Plums are a total failure through the late frosts. *John Basham, Fair Oak Nurseries, Bassaley, Newport.*

Somersetshire.—The cold easterly winds in the springtime did much damage to the fruit trees when they were in bloom. The soil in this

district is of a heavy nature, and lies on the lias rock or limestone, which makes it very cold in winter. *W. Hallett, Cossington, Bridgwater.*

—Seldom has there been a finer promise of fruit early in the year, but the cold weather destroyed most of the Pear and Plum blossoms. Trees on walls we protected by evergreen branches, fish-nets, &c., and in this way we saved a nice lot of the fruits. Where the trees were not thus protected we have no crop. Raspberries have been a great success. Some kinds of Apples suffered much, while others growing beside them have an enormous crop. *J. Crook, Forde Abbey Gardens, Chard.*

WORCESTERSHIRE.—The present is the most disastrous season I ever had to chronicle. We had twelve hours' snowstorm, followed by 16 frost on the night and early morning of April 25 and 26, and this completely destroyed the blossom and fruits that were already formed. Our soil is a medium loam, overlying the new red sandstone formation. *A. Young, Witley Court Gardens, Stourport.*

—The weather of March and April was an alternation of frost, cold winds, and rain, with 19 days in March and 22 in April on which frost was registered. On April 26 we experienced a fall of 4 inches of snow. There was never such a wealth of blossom on the trees. Apple trees when in flower were subjected to a spell of dull weather. The earliest Strawberries, opening in the third week of May, were all black in their centres, though there had been no frost since May 4. *A. A. Pettigrew, Hewell Grange Gardens, Redditch.*

—On April 26 snow fell all through the day, accompanied by wet sleet until 6.30 p.m., when it commenced to freeze. At 8.30 p.m., there was 5° of frost, and the whole of the flowers of Plums, Pears, etc., were frozen hard and stiff. The thermometer registered 10° during the night, which no fruit blossom can possibly withstand. The soil in these gardens is a heavy loam, bordering on stiff clay, with a subsoil of red marl, soft rock. *William Crump, Madresfield Court Gardens, Malvern.*

(To be continued.)

LAYERING CARNATIONS.

THIS work, if not already done, should be proceeded with without delay, as an interval of six weeks must be allowed the layers to form roots before they are severed in October. It is a mistake to introduce over-much fine soil or sand for the roots to penetrate, rather use turfy loam and a little flaky leafsoil, strewing in a quantity of river sand as each layer is pegged in position. By this system the plants will be well rooted when lifting time arrives, and each can be removed with a nice ball of soil attached. When finely-sifted soil is used, it is difficult for water to soak in, and by far the greater quantity runs to waste. During hot, dry weather, the layers should be watered through a small rose every other day or thereabouts until roots and new growths are formed. Before "tongueing" the shoots for layering, each plant should be examined, and the grass or foliage removed up to the point where the slit is to be made. To make the cut, take hold of the young growth with the left hand, and with a sharp knife in the right make a longitudinal incision towards the apex of the shoot about 1 inch long, slipping the knife in just below the joint. This done, gently press down the shoot, which will be the means of opening the severed portion, and with a crooked peg made 4 inches long (the stalks of the common bracken fern are admirable for the purpose) fasten it into the soil, taking care to place a couple of handfuls of mould under each shoot before layering, and a little above it after the shoots have been pegged down. Souvenir de la Malmaison varieties require similar treatment to that detailed above, and after they are severed they require to be planted out in a frame, where they can be lightly shaded for a fortnight. *J. Mayne.*

INDIAN NOTE.

LILIUM POLYPHYLLUM.

ACCORDING to the botanical survey of Northern India, the above charming Lily is indigenous to British Gurhwal, Kumaon, and Cashmere.

Personally I have found two colonies of it, and am aware of a third growing on Cheena Pahar, which is a vast rocky jungle-clad pile in Naini Tal, upwards of 8,000 feet in elevation; the two former colonies are at about 7,300 feet elevation. I have nowhere seen this Lily diffused loosely over large areas, but in strictly colony form.

Moreover, where this Lily thrives the conditions are in all respects identical. It may be said to have selected for itself lofty, cool situations, with a north-west aspect, which is the one in the Kumaon Himalayas turned most directly away from the sun. Though as the sun for four or five months is practically vertical, it must not be assumed that any actual sunless places exist in India through the summer months unless it be for a short time in morning and evening. It is just such situations with a north-west aspect and considerable elevation that will often give the heaviest of jungle and the finest of soil deposits, and this happens to be the case with Lilium polyphyllum in every instance quoted.

The forest is of Indian Oak, arboreal Rhododendron, a species of Acer, &c., together with the world-wide bracken Fern and sundry Himalayan grasses—such are the immediate surroundings of L. polyphyllum. In such situations the Indian Oak, of which there are a number of species, is often a very large and particularly lofty tree, far exceeding the ordinary European tree. It is likewise a very dense evergreen, and this, of course, applies to the Rhododendron tree. Notwithstanding, similar observations applied to sun, will also apply here to shade. In consequence of the great magnitude of the Himalayas, the severe gradients and lofty projection of the mountains, light is practically everywhere most abundant.

These colonies of Lilies are subject to more or less heavy snowfalls annually—some years as much as 10 feet, and occasionally, as in the great snow-year of 1893, I think, not less than 15 feet; and the snow freezes very hard. At the same time it is practically certain frost never reaches the bulbs.

L. polyphyllum flowers in the Himalayas from about the middle of June, or just on the advent of the monsoon as a rule.

I would here draw the cultivator's particular attention to the climatic conditions under which Indian Lilies thrive admirably, and the observations apply to Burmese Liliums in general; also particularly to L. sulphureum.

They are developed right up to flowering time in a warm but dry climate. From March to the monsoon period all through Northern India there is an ever-accumulating state of heat and atmospheric dryness, during which period the rainfall is scanty sometimes extremely so.

The thermometer, even at 7,000 feet, will in June occasionally reach 90° in full shade, though by reason of the dryness of the atmosphere and the delightful Himalayan breezes this temperature is far less objectionable than the same heat in moisture-laden England.

With the arrival of the monsoon a truly stupendous climatic change ensues with marvellous dispatch, and for three months a full subtropical, exceedingly luxuriant growing period ensues, in which vast quantities of rain fall. Vapour dense and prolonged is frequent, temperature is relatively high, and so it continues until about September 15, when all is over, and, generally speaking, about three months of fine dry weather ensue. This should teach the cultivator of Indian and Burmese Lilies the necessity of systematically watering the bulbs up to a corresponding period, and by no means to dry them off or allow them to get dry after flowering for at least two months.

L. polyphyllum, in a state of nature, grows from 2 to 3 feet high on stout self-supporting stems, and each stem will bear from one to three flowers each, borne on the apex of the stem. The flowers consist of three outer segments over ½ inch wide and 4½ inches long; these recurve and finally form loops, as it were, the apex of each segment going quite back to the tube. The three inner segments are 1 inch wide and 4½ inches long, of course, and recurve much less. The base colour is a rich milky white, with numerous minute short streakings of a rich deep vinous red, more particularly along the margins of the segments.

Every segment for more than half its length from base has up the centre of same inside a pronounced green line, and the interior of the tube is suffused with pale green.

It is a delightfully-scented flower, but if any quantity be placed in a room even as large as 35 by 25 feet they develop by night an overpowering scent that is scarcely pleasant by reason of its excessive amount. The bulb of this lily is a very characteristic one, white in colour, small, thin, and pointed, and relatively much longer than wide.

I gather from Mr. Elwes that this Lily is practically extinct in England to-day. I shall be happy to send anyone for *collection purposes* some seed; it is a profuse seeder, germinates readily, and grows freely enough under proper conditions in a rich soil, of which leaf mould should form a large part.

One surprising thing about this distinctly small-bulbed Lily is the great depth it is found in the soil—as much as 15 inches, and 9 to 12 inches always—that the seed got so deep in a wholly virgin place never under the hand of the cultivator is quite impossible; that the bulbs worked down that depth is also extremely unlikely. I therefore arrive at the conviction the depth has been reached by annual increments of soil made by the enormous amount of leafage annually cast off by both Indian Oaks and Rhododendron.

But, even so, it is a very large assumption to suppose that a solid foot of soil has been formed in a century. I suggest that some of these Lilies are indeed much older. The first colony I found was 16 years ago, and it seems to-day just as when I discovered it in a heavy, roadless piece of forest.

In conclusion, it may be mentioned that soil in which these Lilies grow is remarkably first-rate Potato soil, giving an enormous plant, and a fine lot of tubers of the best quality. It is, therefore, a soil rich in both lime and potash, and is most essentially a vegetable soil. *F. W. Sears, Naini Tal, India, U.P.*

PLANT NOTES.

CAMPANULA VERSICOLOR.

CAMPANULAS form some of the most beautiful subjects in the herbaceous border, and among them C. versicolor ✕ deserves special mention. This most charming plant much resembles the well-known C. pyramidalis, both in foliage and in inflorescence. The spikes of large star-like flowers are of a lovely violet-blue shade at their centres, passing to clear sky-blue at the edges, with a delightful Clove scent

This variety does well in a sunny position in deep sandy soil. It will last in flower for a much longer period if given frequent waterings during dry weather.

MULGEDIUM PLUMIERI.

THIS is another delightful plant for the herbaceous border or the rock garden. The foliage is rather large and of a light shade of green. The large panicles of heavenly-blue flowers produce a most charming effect. It is a very ornamental plant, and is one easily propagated. It is raised from seed sown in the open ground in April or in May. They should be planted at a distance of about 1½ feet apart, in sandy soil, where they will need no other treatment than a liberal supply of water. *W. F. Glover, Langport, Somerset.*

PEACH CULTURE.

OUT OF DOORS.

There is no denying the fact that the Peach and Nectarine are not cultivated out of doors in gardens throughout Great Britain and Ireland to anything like the extent that they deserve to be.

In reply to questions I have put to the owners of walled-in gardens and those in charge of them as to why Peach and Nectarine trees were not grown therein, I have been told that they had been tried, but that they did not grow satisfactorily; that the trees became a prey to the attacks of aphides and red-spider during the spring and summer months, adding that they did not think the climatical conditions in that particular district were favourable to the successful cultivation of the Peach and Nectarine out of doors.

Regarding aphides and red-spider attacking the foliage of the trees in the spring and summer months, I may say that the attacks of the former may be easily repressed, and those of the latter prevented if taken in hand in due time, while the question of suitability or non-suitability of climate in such cases cannot be considered seriously by any practical fruit-growers. Indeed, as one who has practised the cultivation of the Peach out of doors in various parts of the United Kingdom (extensively in the south-west of England), and at the same time studied and noted the results—good and bad—attending the methods of procedure followed by others, I have no hesitation whatever in saying that, in my opinion, Peaches may be successfully grown at the foot of and trained up against walls facing south, south-west, and west in any garden in Great Britain and Ireland in which Sweet Cherries, Pears, and Plums succeed. But the trees must be given proper attention in the way of training, disbudding, laying-in of the young growths retained for bearing fruit the following year, and keeping of the foliage free from the attacks of aphides and red-spider, and, of course, the protecting of the expanded blossoms from the effects of spring frosts. I may here remark that, in addition to the cultivator possessing the necessary knowledge of requirements of the Peach and cultural details connected therewith, he should be sufficiently well-manned to enable him to have the work done properly and at the right time.

In making a beginning in the cultivation of Peach trees out of doors the first thing to be done is to determine the sites and the number of trees to be planted thereon of the Peach and Nectarine, and then to select the varieties of each kind, and send the list to some nurseryman having a reputation for supplying good, kindly-growing trees, true to name, ordering good-sized, well-conditioned, dwarf-trained trees to be despatched at the correct time. But in making the list of varieties of the Peach and Nectarine due regard should be paid to the locality in which the trees are to be grown, as, for instance, in admittedly late districts it would be advisable to only plant early and mid-season varieties, such as: Peaches—Early Alexander, Waterloo, Amsden June, Hale's Early, Dagmar, Early Grosse Mignonne, Goshawk, Violette Hâtive, and Crimson Galande (Nectarines, Early Rivers, Lord Napier, Elruge, and Humboldt. For growing in the southern and western counties of Great Britain and Ireland the following varieties should (where wall space is available) be added to those already mentioned: Peaches—Dymond, Golden Eagle, Princess of Wales, Thames Bank, Sea Eagle, and Walburton Admirable; Nectarines—Dryden, Newton, Pine Apple, and Spenser.

Whilst awaiting the arrival of the trees from the nursery, the preparation of the holes for their reception should be proceeded with. Mark the central position of each tree on the wall at from 12 to 15 feet apart with a piece of chalk or charcoal, marking at the same time 2½ feet on either side the central mark, and the same distance therefrom outward, indicating the position in the border with a stick. This, when marked out with a piece of string and stick, will give a semi-circular hole space of 5 feet, and should be excavated to the depth of, say, 2 feet, 3 inches, putting the top spit on one side and the bottom on the other in the process of excavation. Then put about 6 inches deep of brickbats or clinkers, broken fine, on the top in each hole for drainage, but should these materials not be available, stones, with a barrowful of coarse gravel placed on top to fill in the chinks will answer the purpose equally well. Cover these with thin turves, grassy-side down, or stable litter to prevent the soil getting into and choking the drainage.

This done, the question of suitability of soil calls for consideration on the part of the cultivator. However, I may say in passing that the Peach tree is not so particular as to soil as many people assume it to be. That the Peach tree planted in deep, calcareous loamy soil of average fertility will be capable of flourishing and producing heavy crops of first-rate Peaches year after year, without being subjected to any preparation in the way of manuring and trenching the ground prior to planting, I know to be a fact. It is also quite true that good crops can and are being secured from trees planted in ordinary garden or field soil, enriched with a good dressing of well-decomposed stable manure in the process of trenching about 2 feet deep (more or less according to the natural depth of soil), or digging. Of course it is undesirable that the roots of the trees should be submerged during the late autumn or winter months, or, indeed, at any time. Experience goes to show that, heretofore, much unnecessary expense has been incurred in the making of Peach and Vine borders and in the preparation of the composts to place therein. However, where the natural soil is either too light or too heavy in texture to promote and maintain a free, healthy, and fruitful growth in Peach trees, holes must necessarily be made as indicated above, and the excavated soil be replaced with a compost consisting of the best available ingredients at hand, such as turfy loam taken from some remote part of the park or down, broken up with a spade or digging fork. Road-side parings may also be used in this connection with good effect. The loam may be used either by itself or with additions of old lime rubble, wood ashes, and horse droppings, at the rate of one cart load of each to five loads of loam, the whole being well mixed together before being deposited in the holes, leaving sufficient space in each hole to admit of 6 inches deep of soil being placed over the evenly-arranged roots, which should be made to slope gently downwards from the centre when planting; the trees should be put at the same depth in the soil as they were previously, but allowing about 3 inches for the loose soil settling down to that extent within a few weeks from the time of planting. This done, lay on surface dressing of short manure and afford sufficient water to settle the soil about the roots. Secure the branches loosely to the wall until the soil has subsided, afterwards arranging them in their proper positions in due time.

Disbudding—that is, rubbing off superfluous young growths—must not be done at one time: on the contrary, the operation should be extended over several days, doing a little at a time, in order to prevent the trees experiencing any check in the flow of sap. The buds when about one-quarter inch in length should be thinned out to about three or four inches apart on each side of the individual shoots, rubbing off all growths on the upper and lower surfaces of the shoots; those proceeding from the sides of last year's growths being selected at proper distances from one another from the base of each growth for bearing fruit next year.

The attacks of aphides must be looked for as soon as the woodbuds begin a push into growth, and the most effectual way to combat this pest is to syringe the trees with a solution of tobacco juice and water, used in the proportion of one quart of the former to four gallons of the latter, this being applied to the trees after the sun has ceased to shine on them in the afternoon. As a rule one syringing with the solution, if done in time, will suffice for the season. Red-spider may be prevented by washing the foliage thoroughly with clean water applied from a hose, garden engine, or syringe every afternoon, during hot, sunny days, from the middle of May to the end of August. The soil about the roots of the trees should also be kept uniformly moist in this connection as well as for the general well-being of the trees. Thinning out the fruits to about one foot apart is an operation that should be performed as soon as they have attained to the size of large Peas, and not deferred, as is generally the case, until the fruit has stoned, thereby needlessly wasting the forces of the trees. *H. W. Ward.*

THE ROSARY.

THE ROSE GARDEN AT THE MANSE, BRACEBRIDGE, LINCOLN.

A visit to the Rev. C. C. Ellison's garden furnishes at all seasons of the year a source of interest and instruction to those who love a garden, and especially to those who may be more particularly interested in the growth of hardy fruit and Roses. Mr. Ellison is one of the few veterans left of that band of enthusiastic amateur and professional men who made the growth of fruit a special study some forty or more years ago. His contemporaries and friends of that time included the late Dr. Hogg, Mr. Pearson of Chilwell, Speed of Chatsworth, and many others who could be named. Few of those privileged to take part in the activities of those days have been spared to witness the great development which has taken place in the fruit industry of this country since then. But Mr. Ellison works as hard, and enjoys as keenly the delights of his garden now as he did in those early days.

The Rose has claimed him as a devotee as long as have his fruit trees. He dates his love for the Rose back to his early association, and afterwards a long life's friendship, with the late Dean of Rochester. Time has deepened that love, and now, in the evening of his busy life, its culture and the enjoyment of its blooms is a never-failing source of delight and pleasure to himself and his many friends. Five minutes had not elapsed after my arrival at the Manse before we were out amongst the Roses. The first colour mass to arrest one's notice was a magnificent specimen of the Crimson Rambler. It was planted a good many years ago in a corner at the junction of two high walls, both of which it had covered, forming, as it were, a giant cross of glorious crimson colouring. Turning shortly to the right is a wall forming a boundary between the pleasure ground and the fruit garden. On the right of this walk Roses are everywhere in evidence in standards, climbers, and bushes; but this is not the Rose garden. Facing us at the end of this walk is a high screen, formed of strong Oak branches, all completely covered with climbing Roses and summer Clematis in glorious bloom. This is the introduction into the Rose garden, and through a gateway in the screen we gain admittance.

Rose Garden in Compartments.

But before going any further, I ought to say that this garden generally is arranged in compartments or divisions, each complete in itself, forming a garden in itself, in very much the same way as the delightful gardens of the Prince of Monaco at Monte Carlo are arranged only, on the Riviera the hedges are composed of Box, whilst at the Manse the familiar English Hawthorn has to do duty instead. This compart-

ment-arrangement of gardens has much to recommend it, especially in gardens of small or moderate extent. It adds variety and interest to a garden, and helps to focus its contents for pleasurable inspection more effectively than when a great vista, and only that, is exposed to view at one time. The first compartment entered (enclosed within tall hedges) was planted with about 800 well-established strong Roses in magnificent bloom, consisting of Pillar and Standard Roses at the back, with dwarf bushes filling the body of the garden—the whole edged with dwarf Polyantha Roses, the best of them being Gloire des Polyanthas. In planting Roses, Mr. Ellison has originated, or followed, the excellent plan of planting them in groups of three to five plants, and sometimes more of one variety, selecting those colours which in close association with others will produce the most perfect and beautiful effect as a whole. The effect of this method of planting is more pleasing and effective than is the common practice of planting in straight rows with single plants, alternating with other colours in the rows. Certainly the sight, on first entering this garden, will long be remembered, planted, as it was, with the very cream of the best hybrid perpetuals, hybrid Teas, and Teas, all in glorious bloom. Reluctantly leaving this feast of Roses, another gateway in the high hedge brings us to another garden of Roses, similar in many respects to the one we have left, but the colours are differently arranged, and a greater proportion of hybrid Teas planted. No sooner have we left this division and turned a sharp corner of the great hedge, than an entirely different scene comes in view—not a scheme of colour in Roses this time (excepting that we have a glimpse in the near distance of the main Rose garden). The compartment opening to us now is a beautifully planted and furnished water garden, consisting of a circular pond with an elegantly-designed fountain in the centre—the spray from which in the heat of the day, and the shade of the trees which margined the water, gave this garden, after the brilliancy of the Roses, a sense of refreshing repose. The pond is planted with a selection of the best varieties of Marliac's hybrid Water Lilies, and its banks by a choice collection of Reeds and bog-loving plants. Moving to the right by a winding path through a shrubbery, and by the side of a beautiful wide Box hedge planted in serpentine form, the beauty and glory of the real Rose garden is suddenly revealed—and what a galaxy of glorious colouring! This garden is formed like a miniature valley, the sides gently rising away from the centre on each side to a back-ground on the right of the serpentine hedge previously mentioned, and beyond it by a bank of choice flowering and ornamental trees and shrubs. On the left it is bounded by a giant Yew hedge, at the end of which arches of Crimson Rambler Roses are planted, illuminating at the time of our visit the grand old hedge with its beautiful brilliant colouring at this point. At the top of the garden an artistic summer house is placed, from which a delightful general view is to be had of the Rose and the water garden below. This ground in the first instance was only a piece of ordinary level garden land, and its present aspect goes to illustrate the great possibilities which exist, even in small gardens, of producing some very interesting and beautiful effects by a trained and artistic mind. It was the soil and material excavated from the lake which formed the elevations and the possibilities of effect to this garden which Mr. Ellison has so cleverly taken advantage of.

The same principle of arrangement is followed in planting here as in the other divisions, but this portion of the Rose garden being so much larger and the contour of the ground so varied, with the addition of the imposing and splendid background previously mentioned, the effect of the bold colour massing is enhanced. There was only one feature near this garden which seemed to mar the beauty of the whole. It was a wooden framework placed in one corner and covered with tiffany. One was inclined to condemn the introduction of such a feature on to so beautiful a scene, until we approached it near enough to see that Mr. Ellison's solicitude for the welfare of his pet dark Roses was the reason for the insistence of this shading contrivance. I know that a certain amount of shade is essential to the successful growth of dark Roses, as they will not stand for long the hot glare of the sun, but I think that their growth and protection together should be removed to a less beautiful and conspicuous position than this.

NO APHIS, LITTLE MILDEW.

No less remarkable was the healthy and clean appearance of the foliage of the Roses generally than was the great abundance of bloom. Not a trace of green fly was to be seen, and amongst the nearly four thousand plants grown traces of mildew were only seen on about half a dozen plants. The hose and water hydrant to be found at every corner of the garden may in some measure account for this, but I think it is accounted for more fully by the fact that Mr. Ellison eschews those varieties which are known to be weak and poor growers. It is the same with new Roses; they must be well tested before they have the entry into his garden, but once their merits have been proved no one welcomes them with greater cordiality, and only in one case within recent years has he been disappointed, and that has been with Bessie Brown. He is inclined to let her down gently, being a lady; otherwise, I fear to think how her intrusion would have been characterised. The remarkable health of the Teas and hybrid Teas Mr. Ellison attributes to the fact that every winter they are earthed-up to the extent of six or seven inches up their branches with fine, light soil. They are frequently cut down by frost to the top of the soil, but seldom or ever below, and from the growths thus saved splendid plants, many of them two to three feet through, result the following summer. In other divisions of this wonderful garden we came across many old Apple trees given over to climbing Roses, Honeysuckles, and Clematis; many of these they had completely clothed to the height of from 12 to 18 feet, and were at the time of our visit a mass of lovely blossom. Another surprise in store at the turn of a corner was a long pergola clothed with all the best standard climbing Roses, Jasmines, Wistarias, Clematis in variety, Golden Hop, and a host of other beautiful climbing plants in flower.

(To be continued.)

The Week's Work.

FRUITS UNDER GLASS.

By T. W. BIRKINSHAW, Gardener to Lt.-Col. Sir CHAS. HAMILTON, Bart., Hatley Park, Bedfordshire

Ripe Grapes.—Varieties such as Black Hambro', Madresfield Court, and Foster's Seedling will not remain for any period in a good condition after they are fully ripened, but by careful management their season can be somewhat prolonged. During hot weather the ventilators of the glass-house should be thrown wide open all through the day, and a fair amount of ventilation should be allowed all through the night time, to ensure a free circulation of air. Avoid artificial heat as much as possible, for it tends to shrivel the Grapes. Should wet weather set in, a small amount of heat should be allowed to circulate through the pipes, in order to keep the house dry and the berries free from damping. The roof glass should be shaded with thin lime-wash, to break the strong rays of the sun, or the colour in the berries would soon be gone. Examine the bunches frequently, and cut out all cracked and decayed berries, for if these are allowed to remain, sound berries will also soon be affected. The bunches should also be protected from the ravages of wasps and flies. Wasp-proof netting should be hung over the ventilators, but care must be taken in arranging it to allow sufficient space for the ventilators to be opened their widest. This method of protection is a far better system than that of enclosing each bunch in a separate muslin bag, for these do not allow the air to reach the bunches sufficiently, when, consequently, decay soon sets in. Judgment must be exercised in regard to the state of the borders—they must not be allowed to become too dry or shrivelling of the fruits will soon take place; neither must they be kept in a sodden state, or the Grapes will be insipid. Watering should be done very early in the day, so that the surface moisture may disappear before night time. The lateral growth may, if necessary, be cut back a little to allow of a free circulation of air between the foliage and the glass.

Early Pot Vines.—In some establishments Grapes are required very early in the season, rendering the cultivation of pot vines necessary. Every endeavour should be made to have the wood thoroughly ripened, therefore the canes should be fully exposed to sun, light, and air. A somewhat sheltered position outside and one facing south should be chosen for them to ripen, and in such a spot the leaves will not become battered and torn about by the wind. The pots should be partially plunged in ashes, which will save much labour in watering them, for they will not dry out so quickly as otherwise. Weak liquid manure water will greatly strengthen the "eyes" if applied once a week.

PLANTS UNDER GLASS.

By B. CROMWELL, Gardener to T. SUTTON TIMMIS, Esq., Cleveley, Allerton, Liverpool.

Francisceas.—In all stages of their growth these plants should be shaded from the direct rays of the sun, otherwise the colour of both flowers and leaves will suffer. The practice of moving these plants to cooler quarters at the time of opening their flowers is not a safe practice after this date. Afford ventilation to any plants that have passed out of flower, and maintain a summer temperature in the plant house in which they are growing until the middle of September, when it should be gradually decreased until it reaches 55°, at which degree it must be maintained during the winter months. The three points essential to the successful culture of Francisceas are—(1) to keep them liberally supplied with water (soft or rain water should always be used); (2) to train the shoots sufficiently far apart to allow them room for their proper development; and (3) to pinch out the growing points of the shoots in order to encourage the lower branches to develop. Young stock plants raised recently from cuttings should now be re-potted into 5-inch or 6-inch pots. I find a little peat mixed with loam and sand promotes a rich, healthy colour in the leaves.

Plumbago rosea.—The growths of these useful winter flowering plants should be allowed to extend; do not, however, force them into excessive growth by subjecting them to a close, moist atmosphere, but rather grow them under cooler and more airy conditions, which will ensure their flowering profusely during the winter months. Thrips are the most troublesome insects affecting these plants, and these are most easily destroyed by light fumigations. Any plants which have filled their pots with roots should receive occasional waterings of weak liquid manure and soot water. A slight top-dressing of dried fowl manure, passed through a fine sieve, will materially assist them into growth.

Nerium Oleander.—These may now be propagated from cuttings of half-ripened shoots that have shown no sign of flowering. The cuttings should be made with a slanting cut at the base, and should be inserted in thumb pots, filled with very sandy soil. Press the compost very firmly about the cuttings. A moderate bottom heat in a close frame should be afforded them, and when rooted they should be potted and gradually hardened to withstand greenhouse treatment. To ensure success in flowering, plenty of sunshine and ventilation should be allowed them. Soon after the trusses of flowers appear, young growths start from the base of the shoots, and if these are allowed to remain, the flowers are weakened.

Earwigs and Chrysanthemums.—These insects are now in evidence on the young shoots of

Chrysanthemums, and they must be hunted down. Place for them hiding places, where they may conceal themselves at the approach of day. These may be formed of a hollow broad bean stalk, a short piece of bamboo cane, or an inverted flower pot filled with a little dry hay or moss.

THE KITCHEN GARDEN.

By J. Gibson, Gardener to His Grace the Duke of Portland, Welbeck Abbey, Notts.

Winter Vegetables.—The soil should be well stirred from time to time, both between the plants and in the rows of crops intended for a winter supply. In many parts of the south of England Broccoli and Winter Kale have made poor growth in consequence of the drought, and especially in those gardens in which the soil is stiff and clayey, rendering it hard to work. In wind-swept districts slightly earthing the stems will help to steady the plants.

Turnips.—A large breadth of Turnips should now be sown on a piece of well-cultivated ground, with a view to a continuous supply throughout the winter. Sow for the purpose varieties such as Snowball, Orange Jelly, and Chirk Castle. Thin the seedlings early and before they become "leggy."

Globe Artichokes.—The heads should be cut at the proper time and when they are comparatively young. In this dry season earwigs have been a source of trouble, rendering the heads comparatively useless for table purposes in consequence of their deposits. It is difficult to catch all the earwigs, but trapping must be persisted in by means of hollow bean stalks, &c., and in addition pieces of cotton wool should be tied near to the top of the stems, and immediately under the cotton wool the stalks should be smeared with treacle to prevent the pests from reaching the "heads." This should, of course, be done when the inflorescences are quite young, and also when clear of the foliage. Decaying stems should be cut clean away, and the plants be encouraged to make as much growth as possible.

Beet.—Should any of the roots become over large, and promise to deteriorate before the usual time of storing, there need be no hesitation in pulling them. Lift them with care and lay them in soil behind a shady wall, where they will remain fit for use for a considerable period.

Lettuce.—Another large batch of these should be sown to furnish the winter's supply. Grow them from the beginning without a check, and they will then remain a longer period fit for use when matured. All the Year Round is one of the best varieties for sowing now, in fact it is one of the best cabbage varieties for any season of the year.

Winter Tomatos.—Plants newly potted in their final pots, and stood for the present in the open, will require watching to see that they are not saturated by severe rainstorms. The better plan will be to place the plants in frames where the lights can be drawn over them in stormy weather.

THE ORCHID HOUSES.

By W. H. White, Orchid Grower to Sir Trevor Lawrence, Bart., Burford, Surrey.

Vandas.—Orchid collectors inform us that Vanda teres is, in its native habitat in Assam and Burmah, always found in the most exposed and hottest places. Under artificial cultivation it has by experience also been found that to flower this plant satisfactorily it requires exceptional treatment in the matters of light and of sun heat, and where a number of plants are grown and a separate compartment can be conveniently set apart for them, the plants need no shading, provided ample ventilation and atmospheric moisture be afforded. The plants are now growing freely, and some of the stems may have become too tall; these may now be cut off at about 2 feet or 3 feet from the top, and rooted. Insert them in well-drained beds of sphagnum-moss, tying each stem firmly to strong neat stakes, or, if more convenient, plant eight or ten stems in a 7-inch pot in the same manner as that advised in last week's Calendar for Gomesa laxiflora. Another good plan is to tie half-a-dozen or more stems to long, upright, teak rafts, each raft consisting of three or four rods. The lower part of the raft and part of the stem may then be inserted in a pot and made secure with crocks, over which place a layer of fresh sphagnum-moss. Keep the cuttings lightly shaded. Tie all the points of the roots as they form close in to the raft, to which they will soon adhere, and when they have taken a firm hold of the wood they may be gradually exposed to direct sunlight. If no special accommodation for these plants exists, the next best place for them is a sunny corner of the Mexican or the Cattleya house. They should be well syringed overhead several times a day during fine weather, but on dull, chilly days less moisture must be given. The lower stems, from which the tops have been severed, will, if encouraged by heat and moisture, soon produce fresh growths, and in this way the plant may be further propagated. The allied species, V. Hookeriana, the distinct hybrids, V. Agnes Joaquim and V. Marguerite Maron, should also be grown in a sunny position in the hottest house, and be treated exactly as advised for V. teres. The stems may be severed and replanted immediately the flowers fade, which will be about the beginning of September. Stems which have failed to flower may be treated at once. V. Kimballiana and V. Amesiana may be grown in the Mexican house. They require a free circulation of air about them, but neither species care for overhead syringing, and the water, lodging in the axils of the leaves, frequently causes them to become spotted. V. Amesiana should be kept rather more dry at the roots than its allied species, especially during autumn and winter. V. cærulea is generally found a difficult subject to grow for any lengthened time. In many cases the plant is kept in a close, moist atmosphere, whereas it requires an abundance of fresh air at all times, and even during the night time the ventilators nearest the plants should be open more or less, according to the weather outside. Now that the plants are showing their flowering spikes, they need plenty of water, and a light spraying overhead after a hot day will help them considerably. The plants may either be suspended well up to the roof ventilators in the intermediate house, or they may be stood on the side stages in a position that receives plenty of light and fresh air. The same cultural remarks also apply to such hybrids as V. Charlesworthii, V. Moorei, and V. amœna, each of which has V. cærulea for one of its parents.

THE HARDY FRUIT GARDEN.

By W. A. Cook, Gardener to Sir Edmund G. Loder, Bart., Leonardslee, Sussex.

Early Pears.—Very early varieties are, this season, ten days late. Doyenné d'Été and Citron des Carmes are the two earliest kinds, but the latter is a very indifferent Pear at its best, and requires to be eaten directly it is gathered, and Doyenné d'Été is little better. The first Pear ripening, with any merit, is Beurré Giffard, and this is now ready for the table. The tree is a somewhat shy bearer when young, but later, providing it is not overcropped at any time, it furnishes a regular supply. It is a handsome fruit having a red cheek next the sun. The flesh is rich, melting, and sugary. It requires using soon after gathering, as it keeps good for a few days only. Jargonelle, on walls, follows this variety. The fruits may be hastened into condition by gathering them and placing them in a box in a warm place, such as over hot-water pipes or on a sunny shelf. The tree is a strong grower, and very prolific, in consequence of which the fruits require much thinning. Beurré de L'Assomption is a splendid early Pear, very rich in flavour and with a musky perfume, being preferred by some to William's Bon Chrétien. It is very free in growing and cropping. Trees of early fruiting varieties should be well supplied with water. Make secure by tying or nailing all long growths retained for extension, but if the trees have filled their allotted space, pinch or cut the laterals back to one leaf. Moincrop and late varieties should not be allowed to suffer from lack of water at their roots. Where possible, the trees should be well syringed with the hose pipe during the long, hot evenings, for this will cleanse the foliage and water the roots at the same time.

Plum Trees.—The growths should be nailed and tied, and unnecessary ones pinched again as this all helps the fruits to develop. The trees should be kept clean by frequent washings, which will also help to keep the roots moist especially where a heavy mulching has been placed over them. Late Plums should be more severely thinned than early ones. Such first-class varieties as Transparent Gage, Jefferson's Gage, Coe's Golden Drop, Green Gage, Kirke's Seedling, and Peach Plum need heavy thinning, high feeding, and careful stopping and pruning. Kitchen Plums are also better when the fruits and growths are properly thinned and regulated. Large fruits are very serviceable for bottling. Remove all suckers from the stems, and keep the foliage free from insect pests.

Late Cherries.—The trees must be kept clean by frequent washings, and be netted to keep away birds. Morello Cherries can be kept for a long time when carefully protected, but during a very hot season they will also need protection from wasps, and this can only be done with very fine meshed netting; late varieties, however, are usually grown on north walls, where these pests are not so troublesome as on warmer situations.

THE APIARY.

By Curtis.

Re-queening.—This is a suitable season of the year at which to re-queen. Were a good farmer about to re-stock or provide a good male of any kind, he would desire one of good pedigree; but in beekeeping many ignore pedigree, and are quite ready to take any queen, irrespective of its descent, whilst others simply introduce foreign races without knowing their peculiarities.

Carniolans are very quiet bees to handle, and very prolific. They cap their honey almost as well as the native bee, the cappings being white; but they are given to excessive swarming, and on this account many beekeepers have ceased to keep them. There are some good strains which have been produced by careful selection.

Cyprians are very pretty bees, and many stories of large crops of honey taken from them are recorded. They are very excitable and difficult to handle, consequently they should never be disturbed unless the operator wears a veil, and the smoker should be fully ready. Another race of like temper is the Syrian.

Ligurians or Italians are easily distinguished by the three yellow bands around their abdomen. They are very prolific, and during the spring breeding goes on by leaps and bounds. When the honey season arrives they seem to curb their excessive breeding, and this gives place to honey collecting and storing. They are a quieter race than the other foreign kinds mentioned, and whilst many of the other kinds take to the wing when the frames are raised during an examination of the hive, these remain on the combs. They possess a long tongue, and they can gather deep-seated honey which could not be reached by the native bee. They are, generally speaking, admirably suited to the production of extracted honey.

The native bee produces better-sealed sections than any other race, for many of the others fill the cells very full of honey and seal them with a thin capping, which gives the sections a watery look.

In choosing a queen there are many points to be considered. Temper is an important trait, and, as a rule, hybrids seem to inherit all the bad qualities of both races from which they are raised. Some imagine a prolific queen is a great desideratum, but of what use is this if, combined with it is the undesirable habit of excessive swarming? Other points to consider are the disposition to build brace combs, and bad capping, which, if of a watery appearance, detracts greatly from the value of the sections and loses points on the show bench.

We should look to our apiaries to discover whether we may not, with advantage, utilise our own stocks for the purpose of re-queening. The beekeeper who has kept a correct record of the doings of each stock can destroy the queen of a desirable strong colony, and the bees will at once set to work to raise other queens. In about a week the queens that are to be replaced may be removed, and these stocks will also set to work to produce other queens. When they have been queenless for about four or five days, the queen cells may be removed, and other queen cells taken from the first hive may be secured very carefully on the frames. The young queens will hatch in 14 days from the removal of the first queen, and will probably be laying in a week or ten days.

The best queens are always raised from stocks that are at the swarming point. Weak colonies are useless for the work of producing desirable queens.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, *as well as specimens and plants for naming, should be addressed to the* **EDITOR, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Special Notice to Correspondents.—*The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.*

Illustrations.—*The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c., but he cannot be responsible for loss or injury.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.*

Local News.—*Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

APPOINTMENTS FOR THE ENSUING WEEK.

TUESDAY,	Aug. 21	Brighton Fl. Sh. (2 days).
WEDNESDAY,	Aug. 22	Harpenden Hort. Sh. Shropshire Hort. Soc. Sh. at Shrewsbury (2 days).
THURSDAY,	Aug. 23	Aberdare Fl. Sh.
FRIDAY,	Aug. 24	Devon & Exeter Fl. Sh.
SATURDAY,	Aug. 25	Dutch Gardeners' Soc. meet.

AVERAGE TEMPERATURE for the ensuing week, deduced from observations of Forty-three Years at Chiswick—61.5°

ACTUAL TEMPERATURES:—

LONDON.—*Wednesday, August* 15 (6 P.M.): Max. 71°; Min. 58.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—*Thursday, August* 16 (10 A.M.): Bar., 30.0; Temp., 67°; Weather—Fine.

PROVINCES.—*Wednesday, August* 15 (6 P.M.): Max. 65° Norwich; Min. 55° West Coast of Ireland.

SALES.

MONDAY—
5,000 lots of Dutch Bulbs, also Lilium longiflorum, L. Harrisii, Palms, Seeds, &c., at Protheroe & Morris' Rooms, at 10.

WEDNESDAY
Dutch Bulbs at Protheroe & Morris' Rooms, at 10.

THURSDAY—
Dutch Bulbs at Protheroe & Morris' Rooms, at 10.

The Royal Botanic.

The affairs of the Royal Botanic Society ought to have an interest for the horticultural community. That they possess it in so slight a degree appears to us to be due to the exclusive policy so long pursued by the management. These are democratic days, and this is a period when a Society, of whatever nature, has to justify its existence or be crowded out. We are afraid the warmest friend of the Society must admit that its right to the title of "Botanic" is but feeble, and that its claim to be a representative of Horticulture is not much (if any) more valid. Half a century ago botanical students used to wonder what the Society did to act up to its title, and they are still wondering. They are wondering, too, how the Royal Horticultural Society, which at one time stood sorely in need of assistance, received no encouragement from the Government, although it had done so much, whilst the sister Society, whose claims to public help were so greatly inferior, received favourable consideration. The gardens in the Regent's Park are well known for their beauty, and they contain, and always have contained, an interesting collection of plants. They have been useful in furnishing specimens for generations of botanical students. In their present condition they confer much credit on the able superintendent, Mr. Hawes, and yet we hear little but of dissensions among the Fellows, of heavy debt, of expenditure exceeding income, and of relatively a very small number of additional Fellows.

The precise causes of these depressing conditions we can only guess at. The Society has been so out of touch with horticulturists that very few of them have sufficient first-hand acquaintance with the affairs of the Society to enable them to offer an opinion, even it were asked for, and, worse still, they have little interest in the matter. It seems to us that the Society has relied much too exclusively on exhibitions, garden-parties and similar distractions. These things, of course, have their value, and are not to be despised, especially from a commercial point of view, but they do not appeal to those who have the advancement of horticulture and botany at heart.

Reforms have been from time to time proposed, the precise value of which we are not able to estimate, but, at any rate, they have not hitherto commended themselves to the Council, or to the Fellows assembled in general meeting. At the annual meeting held on the 10th inst., a proposal was made that five members of the existing Council should retire and be replaced by others, but this proposal was negatived by a large majority.

The total income was declared to be about £380 less than in the previous year, but it was pointed out that the excess of expenditure over income was "only" £975 as against £1,237 in the previous year. Some new bye-laws giving the Fellows more control were proposed, but the rule of a qualified, intelligent and benevolent Dictator would seem to be the greatest want of the Society in its present state.

SUPPLEMENTARY ILLUSTRATION—YUCCAS. Among the most effective plants that can be used in the decoration of the garden or the lawn, certainly the Yuccas take a foremost place. There are many species and varieties, but on the whole there is none superior to Y. gloriosa. Its hard, rigid leaves, alike on both surfaces, and therefore provided with a double breathing apparatus, enable it to withstand even the more or less mephitic atmosphere of our great cities. Most of the species are quite hardy, and although some over-careful gardeners tie up the leaves into a mass during the winter, we have generally found that much more harm has accrued from the accumulation of moisture in the centre of the crown and consequent rotting than from frost, however severe. Yuccas have been flowering freely this year in the vicinity of London, and many a suburban garden has been glorified by the noble panicles of ivory-white flowers. The Viscount HORNCASTLE sends us a photograph of a specimen which has flowered with him this season at Taymouth House, N.E., concerning which he gives the following particulars:—Height, 18 feet 6 inches; flowering panicles, three, densely covered with blossom—and this well within three miles from Cheapside! The species were monographed in our columns by Mr. BAKER in 1870. Yucca filamentosa and Y. flaccida are the species most usually seen after Y. gloriosa. They are mostly natives of Mexico and the arid countries in its vicinity, where they grow under conditions about as different from those which prevail in a London garden as it is possible to imagine, thus affording another illustration of the circumstance that plants do not always grow under what we should consider the most favourable conditions, but where their competitors will allow them to grow. Our illustration, by Mr. E. J. WALLIS, represents a group of these handsome plants flowering in the Royal Botanic Gardens, Kew.

NATIONAL POTATO SOCIETY.—On Saturday, 11th inst., an inspection of the trials of Potatos conducted at the Cambridge University Farm at Impington, near Histon, was made by some members of this society. The visitors were conducted over the farm by Prof. T. H. MIDDLETON and Mr. H. HENSHAW, under whose directions the trials are being carried out. Notwithstanding the drought, the crops were looking exceptionally well. Trials of seedlings are being conducted by the society on behalf of various raisers.

BANK HOLIDAY AT KEW GARDENS.—A record crowd of 113,131 persons visited these Gardens on August Bank Holiday, this number being about 7,000 greater than the previous highest on record. One of the most popular routes to Kew from London is by steamboat, and although 11 steamers were running, they were not nearly sufficient to bring the numbers who congregated at Chelsea pier. The daily papers sometimes record throngs of people scrambling to get on the London County Council trams at Blackfriars Bridge, but that is nothing compared to the crowds who besieged the electric cars at Kew Bridge on Monday evening.

KEWITES AT CRICKET.—A cricket match arranged between "past and present" Kewites took place last year for the first time. It has been repeated, and this year's match was played on Kew Green, on Wednesday, August 8, when the "past" proved successful, thus reversing last year's result. Scores: Past, 120 (TRIBBLE, 41); Present, 77 (BOWELL, 38). For the winners SIMMONS took four wickets for 27 runs, and THOMAS three wickets for one run. On the losing side BOWELL claimed eight wickets for 48 runs. After the match tea was partaken of in the garden library.

LONDON DAHLIA UNION.—The annual show of the above society will be held on September 18 and 19, in the gardens of the Royal Botanic Society, Regent's Park. The exhibition will be held in the large conservatory and long corridor. An additional attraction will be found in the entire range of greenhouses and hot-houses containing the Victoria Water Lily, Bananas, Sugar, Tea, Coffee, and other economic plants. Moreover, the whole of the gardens will be open to visitors to the Dahlia show. The schedule and all particulars can be procured from the secretary, Miss DEAN, 18, Ranelagh Road, Ealing, W.

BEECH TREES AND LIGHTNING.—The question as to whether Beech trees are liable to be struck by lightning is at present arousing considerable discussion. We note a reference to the subject in the *Museum Gazette*, a somewhat new journal published at the Haslemere Educational Museum and in London. In an answer to a correspondent one of the editors (perhaps Dr. JONATHAN HUTCHINSON), says that "the statistics collected by M. FLAMMARION showed that the Beech was as much liable as the Ash. His numbers were 54 Oaks, 21 Poplars, 14 Elms, 11 Walnuts, 10 Firs, 7 Willows, 6 Pines, 6 Ashes, 6 Beeches, and a few of a great variety of others. These statements applied to France, and very much depends upon the relative abundance of any given tree in the locality. Not improbably Mr. HARVIE BROWN (who has asked if Beeches are ever struck, and suggested that they are not) has never known Walnut struck, for Walnuts are far less common in England than in France. At Haslemere we have but few records of Beeches being struck, but then large Beeches are not common, and are very usually protected by other adjacent trees, which, towering much higher, serve as lightning conductors. The Birch is not mentioned once in M. FLAMMARION's list, but very possibly there were few or none of large size in the districts concerned. It is certain," concludes our writer, "that Beeches are not immune, and when struck are usually splintered."

Chatsworth. — Mr. Jennings, foreman at Rangemore, and son of Mr. Jennings, of Ascott gardens, has been appointed at Chatsworth, in place of Mr. W. Chester.

Intermediate Science Examination.—Miss E. M. Hemsley, the daughter of our correspondent Mr. A. Hemsley, was among the successful candidates at the recent examination at the University of London.

What Science has Developed. — Seed growing has had its new birth as well as other operations in the arts and sciences—a new birth noticeable to every one in improved implements and tools, all great labour-savers, but best illustrated by noting the development along scientific lines, as for example:—(1) The use by seedsmen of carbon-bisulphide and hydrocyanic acid gas in killing the weevil in seeds; also in killing under-surface insects and grubs; (2) In spraying garden plants to stop on the one hand insect ravages, and, on the other hand, to stop the extension of fungous diseases; (3) The use of electric light as introduced in France to force a night-time growth of vegetables cultivated in forcing houses, a growth equal to 10 per cent. additional development and precocity; (4) The practice of nitroculture in connection with plants of the Leguminosæ family, an inoculation with commercially-made cultures of nitrogen-fixing bacteria, much advancing the immediate development of Peas and Beans and laying up a store of stimulating food for succeeding crops; (5) The artificial passage of electric currents by some German experimenters through the length and breadth of plant beds in vegetable forcing houses for the purpose of stimulating increased cellular action, equal, it is said, to 10 per cent. development; (6) The use of chloroform to produce an intense rest which makes it quite possible subsequently by the application of moisture and heat to gain 60 days advancement in the blooming of flowering and fruit plants; (7) The use of electric air currents to stimulate the growth of garden and field crops, a gain of 20 to 60 per cent.; (8) The electrocution of insects feeding upon vines and plants both on their above and underground surfaces, particularly applicable in the case of Grapes, Roses, and fruit trees; (9) And among the latest scientific developments in connection with agriculture is the extraction and holding by mechanical and chemical means of atmospheric nitrogen, and its subsequent incorporations with other things in the making of a commercial fertiliser, the air offering a limitless mine out of which to collect the most important of all plant stimulants. This generalisation indicates that the higher practice of agriculture and horticulture, of which the seed grower is the first exponent, has already become one of the sciences. *Florists' Exchange.*

Nitrates from a Fresh Source.—According to a paragraph in a recent issue of *Le Jardin*, MM. Muntz and Laine have recently reported to the Académie des Sciences the discovery of a new source of nitrates. When peat is mixed with lime and then sprinkled with nitrifying ferments it very soon forms into large blocks of excellent chemical manure. This discovery entirely justifies the opinion of those agriculturists who propose to enrich peaty soils and field soils too rich in humus with calcareous matter or with chalk so as to increase its fertility. But there is a yet more important consideration. The experimenters obtained products which yielded 8 kilogrammes of nitrate per cubic metre per day, whereas former experiments only yielded five in two years. To produce this nitrogen the inventors distilled Peat in a current of superheated steam. They thereby obtained not only the whole of the nitrogen but also methylic alcohol, tar, and a combustible gas. They declare that from the Peat-beds of France quantities of nitre can be obtained comparable to the enormous supplies from Chili. Our Irish friends should investigate this matter.

The Legion of Honour.—M. Nanot, the Director of the National School of Horticulture at Versailles, has been promoted to the rank of Officer, and M. Poisson, for many years an assistant in the Herbarium at the "Museum," has been made a Chevalier of the same Order.

Preservation of Fruit.—The Board of Agriculture recommends the plan of immersing the fruit in cold water containing 3 per cent. of trade solution of formalin. Soft fruit are immersed for 10 minutes, then taken out, placed in clean cold water, and afterwards laid out on strainers to dry. At Kew Strawberries, Cherries, Gooseberries, Pears and Grapes were so treated with good results. Apples need only to be immersed for 10 minutes in the formalin solution and then dried, and placed when dry in the fruit-room. The formalin is quite harmless and the expense very little. It acts by preventing the growth of those fungi and bacteria which bring about the rotting of the fruit.

How to Cope with the San Jose Scale.—At the Illinois Agricultural Experiment Station investigations have lately been made with eleven different insecticides to prove which of them is most effectual in checking the San José scale. According to Mr. S. A. Forbes, in Bulletin No. 107, the cheapest and most efficient of the eleven insecticide mixtures thoroughly tested against the San José scale was a simple lime and sulphur mixture (without salt or blue vitriol), dissolved by boiling together. It was prepared from 15 pounds of Marblehead lump lime and an equal weight of sulphur to 50 gallons of water. The sulphur was first put into 12 gallons of water nearly at the boiling point, after being mixed with enough water to form a thin paste. The lime was then added and the mixture was boiled for 40 minutes with the necessary stirring. The whole was strained into a 50-gallon tank, which was then filled with water. The cost for materials was from 84 cents. to 1·03 dollars (3s. 6d. to 4s. 2d.) per hundred gallons of the fluid spray, varying according to the proportions of the chemicals used. Infested trees treated with these solutions in March bore about one-fifth as many scales the following September as companion trees not treated. There was a marked and very important difference in the final effect of these washes and mixtures, dependent upon the time of their application, the mid-winter treatment yielding a result far inferior to that of early spring.

Photographs in Colours.—Mr. T. Waltham has submitted for our inspection some very beautiful photographs, in which the colours of the flowers are brought out with great vividness and accuracy. Some views in the garden at Wisley showing the Lily pond, and some representations of Cattleyas and other Orchids, are excellent illustrations of the progress that has been made. Mr. T. E. Waltham's process of reproducing nature in colours, although differing somewhat from the three-colour process of colour photography, relies upon the negative to give the colour-values of the object to be photographed. The three-colour process, while theoretically perfect, is not yet altogether successful in actual application, the breaking up and subsequent re-blending of the three primary constituents of white light presenting considerable technical difficulties. Mr. Waltham utilizes the camera and its accessories up to the very last stage in his process, but here, at the point at which practice begins as it were to get out of step with optical theory and to lag behind, he substitutes an after treatment of his own devising; this treatment, constituting the finishing stage, is somewhat difficult and tedious at present, but whatever the difficulties to be overcome he guarantees a permanent and faithful representation of the flower or other object entrusted to him to reproduce. Mr. Ernest Waltham's address is 97, Upper Tulse Hill, S.W.

"The Tatur Disees."—His Majesty the King has, we learn, accepted a copy of Mr. Chas. T. Druery's book representing the humorous side of Horticulture, and expressed his pleasure at its receipt. The book is prefaced by the author as follows:—

> "A little nonsense now and then,
> Is relished by the wisest men;
> And even Solomon, no doubt,
> Was not a 'solemn-un' throughout.
> So since a hearty laugh's a tonic
> 'Gainst evils brief and evils chronic,
> The author hopes his quips and cranks
> Will merit even Royal thanks."

The volume is published by the author at Moorgate Station Chambers, E.C.

Mendelian Dominance: a Correction.—Mr. Bateson writes: May I correct a slip in your report of the Hybridisation Conference, on p. 116, col. 3, in the discussion on Mr. Worsley's paper on Hybrid Amaryllids, &c. I am reported to have said that: "It was essential to Mendelian results that there should be dominance." What I said was that it was *not* essential. We know some simple Mendelian cases where there is no dominance of one character, but rather a blending (*e.g.*, the Andalusian fowl, where the two pure types are black and splashed white respectively, while the crossed type is blue). In many examples, also, though the inheritance follows typically Mendelian rules, dominance is by no means complete. There have been such frequent misunderstandings on this matter that it seems desirable to insert a correction. *W. Bateson, August 10, 1906.*

Thefts of Rubber Seedlings in Malaya.—Mr. H. N. Ridley, in the *Agricultural Bulletin of the Straits and Federated Malay Straits*, warns planters to keep an eye on their Rubber nurseries. He says that "The demand for plants and seeds, especially for Dutch territory, is so large that it has become worth while for Malays to raid plantations by night and convey the plants to Singapore, whence they are shipped to Dutch Borneo. Upwards of a thousand seedlings were stolen from the nurseries at the Botanic Gardens in one night, and a planter in Malacca lost 10,000 in three raids. Investigations in Singapore disclosed the fact that a very large export of seedlings has been going on from Singapore, chiefly to Banjermassin, at the rate of from 13,000 to 30,000 a week. Few, if any, of these are cultivated by the exporters, most of whom say they obtained the plants from Klang. One man was recently charged with fraudulent possession of 13,000 plants, but was acquitted as the evidence wanted was in the Native States, and not procurable. It seems probable that the nurseries are raided by night, the plants pulled up and taken by native boats to Singapore, so as to avoid their being seen on board a steamer leaving for Singapore, and they are then sold to the exporters for shipment. At one time it was proposed to prevent the export of Rubber seedlings from the Malay Peninsula, except to British Colonies; it is regrettable that this was not carried into effect, as the supply of plants is by no means large enough for our own requirements, and it would then have been possible to check these robberies."

Useful Fruit-Culture Charts. — In spite of the uncertainty of the fruit crops in these isles, owing to the unpropitious weather frequently experienced at a critical period in spring, the advice to those having gardens or farms to plant fruit trees, on a portion of the ground at least, is as sound as it is general. But if fruit cultivation by the masses be desirable, it is certainly expedient that those entering upon its cultivation should have easy means of obtaining reliable information upon the best manner of carrying out the necessary details. It is from this point of view that we welcome a set of five charts, drawn by Miss Lorna F. Bunyard, which illustrate very clearly the right and wrong methods of carrying

out the operations of (1) Planting; (2) Propagation by cuttings and layers; (3) Pruning; (4) Budding; and (5) Grafting. In the matter of planting, the directions given are of the most orthodox description; a proper hole is to be made for the reception of each tree, and the roots must be laid out at various levels with the utmost care. It is evident, therefore, that the results obtained from experiments made at Ridgmont, and which seemed to show that the best results followed when a young tree was simply stuck into the ground without the exercise of any care whatever, has not yet caused our fruit growers and teachers to modify their practice in the least. We are not surprised that such is the case, believing that there remains much to be disproved before these time-honoured and satisfactory principles of cultivation can be safely discarded. There is nothing new either in the illustrations of propagation by cuttings, of pruning, or of grafting, but such important details cannot be too often taught, and the drawings teach them in a more effective manner than can be done in prose. A small handbook, to amplify the teaching of the illustrations, has been compiled by Mr. GEO. BUNYARD, V.M.H., assisted by the Rev. W. WILKS, M.A., and issued at the price of 6d. each The price of the set of five charts is 5s. net. Both are published by Messrs. W. H. & L. COLLINGRIDGE.

Publications Received.—*Experimental Farms, Ottawa.* Reports for 1905. The harvest was bountiful and the crops gathered very satisfactory over the settled parts of the Dominion. Dr. W. Saunders records a large and increasing demand by farmers of publications issued from the experimental farms and increasing work in all departments.—*The Sports Times*, New York.—*Agricultural Gazette of New South Wales*, May. Contents: Formalin and the Germination of Wheat, D. McAlpine; Forestry, J. H. Maiden; Botanical Work at the Hawkesbury College, C. T. Musson, &c.—*Journal de la Société d'Horticulture du Japon.* With many illustrations and articles in Japanese and in French.—*Country Life in America.* An attractive paper, somewhat on the lines of our British periodical of similar name. It deals with all matters concerning the country, and is well illustrated.

HYBRIDS AND HYBRIDISATION AMONG BULBOUS PLANTS.*

THE following is an enumeration of some of the hybrids among bulbous and tuberous-rooted plants that were raised in my establishment:—

Lilium.—Very numerous crosses among various species were effected by me, and many seedlings are still under observation; a good and noteworthy race has sprung from the crossing of Lilium Martagon album with Lilium Hansoni. It is of particular interest to note, that whereas Lilium Martagon album, if raised from seed, almost comes perfectly true, scarcely ten among a thousand plants reverting to the typical purple Martagon Lily; out of the mingling of Lilium Martagon album with L. Hansoni not a single white Martagon occurred. All plants (several hundreds) that showed no influence of the pollen parent (L. Hansoni) reverted to the typical purple Martagon Lily. Those that showed the influence of L. Hansoni developed into stately, tall-growing Lilies with broad, dark-green foliage in whorls and pyramidal spikes, composed of very numerous flowers. The ground colour of the flowers of these hybrids is a more or less pronounced pale buff-brown, either flushed with crimson or with deep orange and with purple spots. The individual size of the flowers much exceeds that of either parent. I named this strain Lilium mar-han, and, as far as is known to me, the cross effected by Mr. Powell, of Southborough, between L. Martagon dalmaticum and Hansoni either produced true hybrids or gave dalmaticum pure. Other crosses which gave good results were effected between L. pardalinum and Parryi and also between L. pardalinum × Humboldti. These, however, have lately also been raised in America.

Brunsvigia Josephinæ.—This remarkable plant freely flowers with me, and I several times fertilised it with pollen of Amaryllis Belladonna. I have now large bulbs, 4 to 6 inches across, of these hybrids, which so far have not yet flowered, although some are over ten years old. It is very remarkable that the plants, though raised from seed of the Brunsvigia, show no influence of the mother parent, the bulb and foliage being that of an Amaryllis Belladonna.

Colchicum.—Some very interesting plants came from a cross between C. Sibthorpii and the double white-flowered form of Colchicum autumnale. The seedlings either produced a large, broad-petalled form of C. Sibthorpii or gave perfectly double-flowered C. Sibthorpii, the flowers being composed of hundreds of narrow petals of a lilac red, faintly chequered white. These double flowers are perfectly sterile, whereas in the double white-flowered Colchicum autumnale one occasionally finds a good pistil and potent pollen.

Eremurus.—Some very strong-growing hardy hybrids, capable of resisting severe late spring frosts, which will kill or hopelessly damage flower-spikes and foliage of robustus and himalaicus, have been raised by crossing E. himalaicus with early-flowered forms of E. robustus, the result giving a fair percentage of immensely strong growing plants, throwing spikes 7 to 8 feet in height with flowers of a pale-rose colour. These hybrids flower a little later than E. himalaicus and before those of E. robustus are out. Though not so showy as a finely-developed specimen of E. robustus, the hybrid which I named Eremurus him-rob has the particular advantage of being capable of escaping the injurious effects of late spring frosts. A very interesting and delicately beautiful plant is Eremurus × Tubergeni, which was produced by crossing E. himalaicus with pollen of an early-flowered form of E. Bungei. In this plant the foliage has the deep-green colour of that of E. Bungei, but being almost as broad as that of E. himalaicus, while the spikes and individual flowers most resemble those of E. himalaicus, the colour being a delicate pale primrose yellow. Seedlings of this hybrid either produce true E. Tubergeni or E. himalaicus, but I have not observed any E. Bungei to reappear among them. Hybrids between E. Bungei with robustus or Olgæ (the latter were also raised in Sir Michael Foster's garden at Shelford) give plants in which a coppery salmon yellow of the flowers predominates. In habit of growth and colour of the flowers some of the seedlings cannot be distinguished from E. Warei, which I have always regarded to be a natural hybrid between E. Bungei and some rosy-coloured sort and not a true species.

Freesias.—Up to very lately these charming plants only occurred in white and creamy yellow shades, and though yearly raised by the million from seed in France and Italy, seem to have sported very little. Crosses between the small flowered orange-yellow F. aurea and refracta gave interesting hybrids, but not an improvement on either parents. The advent of the rosy-crimson flowered F. Armstrongi from South Africa has been a most welcome addition, as this at once opened a wide field for bringing some more variations of colour among these popular flowers. F. Armstrongi itself being a rather delicate grower, I made no attempt to fertilise it with pollen of refracta alba or Leichtlini, but placed pollen of Armstrongi on as many different shades and forms of F. refracta, F. refracta alba and F. Leichtlini as I could get hold of. The results, so far, have been most encouraging, and I have now a strain of tall growing Freesias with up to nine individual flowers on every spikelet, of which every bulb produces several, in colours varying from the palest rose to carmine and purple-red. A small percentage also came in shades of orange-buff and coppery-rose. A selection from these seedlings, with flowers of a violet-rose shade, I have this spring exhibited at one of the fortnightly meetings in the Hall, and an Award of Merit has been given to it by the Floral Committee. I also attempted to cross F. Armstrongi with F. aurea and vice versâ, but with very poor results.

Gladiolus.—So many magnificent strains of hybrid Gladioli now being grown, I made no special attempts to further improve the various races known as gandavensis, Lemoinei, Nanceianus, Childsi, and others, but specially turned my attention to the original species. Thus far I must own that although a good many very pretty hybrids have been raised in my establishment, I have up to now only one or two strains in these Gladioli that may prove useful commercially. A selection out of crosses between G. alatus and G. cuspidatus are dwarf growing, very free-flowering Gladioli that flower in the open ground quite three weeks before the earliest of the nanus or ramosus sections, which, as is well known, precede the gandavensis and other strains in time of flowering by from three to four weeks. These alatus × cuspidatus Gladioli, apart from their usefulness in flowering so early in the open ground (end of May), are very welcome additions to the Gladiolus genus, as each bulb produces from two to five spikes of about a foot high with flowers of fair size and of a charming colouring of rosy-salmon with golden-brown markings. They are just the thing for filling small glasses for table decoration, and other choice floral work. This strain I named Express, and from various persons I have already received letters expressing satisfaction with the habit, time of flowering, and general usefulness of these Gladioli.

Hymenocallis.—With a view of ascertaining the correctness of the supposed parentage of H. macrostephana, after some years' trial I managed to have the two supposed parents, Hymenocallis speciosa and Hymenocallis (Ismene) calathina in flower at same time. The results showed plants absolutely different from H. macrostephana, being much broader and thinner in the leaf; the formation and size of the inflorescence and of the individual flowers also being quite different. When in good condition this hybrid Hymenocallis, the first authentically on record between the evergreen section Hymenocallis and the deciduous Ismenes, is a magnificent plant with an umbel of over a foot and a half across, with individual flowers large, snowy white, exceeding in size even those of the so large-flowered H. macrostephana. This hybrid has been distributed under the name of H. Daphne. Crosses between the white H. calathina and the yellow, green banded H. Amancaes gave charming mules of a delicate sulphur-yellow. These, however, have also at various times been raised in England.

Iris.—The deep sandy soil and the climate of Haarlem seeming to suit a very large portion of the Iris tribe, from times immemorial the Irises have been grown and improved by the Dutch cultivators. The Xiphium (Spanish) and xiphioides (anglica) strains, if raised from seed, will still yield agreeable surprises, but it is doubtful whether these really differ from those that were in cultivation a hundred or more years ago. So many species of Xiphium now being in cultivation that were unknown to our ancestors, I some eight to ten years ago commenced intercrossing the Spanish, Portuguese and Moroccan species of Xiphium, not using, however, the ancestors of the strain that are now known as the Spanish Irises. From these crosses various modifications at last resulted in a highly important race of very large-flowered Xiphiums of the form and shape of the Spanish Irises, but flowering quite a fortnight earlier. The flowers of this strain (which is not yet in commerce) now show the same range of colours as is met with in the ordinary Spanish Irises, but the flowers are of unusual size and great substance, the falls being from 1½ to 2 inches

* A Paper presented to the recent Hybridisation Conference, By C. G. Van Tubergen, Jun., Haarlem, Holland.

across and the entire flower measuring over 4½ inches from tip to tip. It is interesting to note, that whereas in the ordinary Spanish Irises the yellow colour is so abundantly represented, it was only in the later and latest generations of seedlings of my new strain that good and pure yellows have been developing. It is also interesting to note that by continually selecting the earliest flowered varieties, the strain now obtained flowers fully a fortnight in advance of the ordinary Spanish Irises. Among species of the reticulata group the mingling of the richly-coloured I. Bakeriana with selected forms of histrioides and reticulata gave charming combinations of colour among these so early-flowering gems. The influence of I. Danfordiæ so far is not yet apparent. The Juno group of bulbous Irises which in the last dozen years received important additions by the introduction of so many Asia Minor and Central Asiatic species presented another field of work. These Irises usually flower at the time when sharp late night frosts occur, and are therefore not easy to cross, or rather to obtain good seed from. My earliest successes in this group came from crossing Iris persica with the purple I. persica purpurea and from hybrids between I. sindjarensis and I. persica. The former I introduced under the name of I. purpureo-persica and the latter as I. sind-pers, both obtaining awards from the Royal Horticultural and other Societies. Later crosses produced the lovely I. sind-pur (I. sindjarensis × I. persica purpurea), I. pur-sind (the reverse cross) and others. The principal charms of these early-flowering bulbous Irises are their extreme hardiness, their free-flowering character, and their rich colouring.

Rhizomatous Irises.—No section offers greater interest to the plant-lover than the extremely interesting and beautiful section of Oncocyclus and their near allies the Regelia. Considering the great care that in our climate the successful cultivation of the Oncocyclus group demands it has been my aim, by intercrossing the latter section with the easily-grown Regelia, to raise a strain that was to combine the beautiful and large flowers of the true Oncocyclus with the hardy character and free-flowering qualities of the Regelia. I tried crosses both ways, but soon found that hybrids raised from the Oncocyclus with the Regelia did not possess any more vigour than their seed parents, whereas the Regelia section (I. Korolkowi and varieties, I. Leichtlini, I. vaga, etc.), crossed with the Oncocyclus gave birth to a hardy, free-growing and free-flowering race. Some of the varieties raised from these crosses have now been in cultivation in my establishment for over eight years. In point of vigour and free-blooming qualities this new race, which has been distributed under the name of Iris Regelio-cyclus, leaves nothing to desire. Another point in favour of this race is that in the open ground it flowers with the very earliest members of the rhizomatous Irises, such as I. præcox and some pumila varieties, preceding the host of ordinary bearded Irises (germanica) by from three to four weeks. From the Regelia parents they also inherited the desirable property of producing two flowers on each scape, a second flower taking the place of the first on withering. Especially beautiful in this strain are the hybrids of selected varieties of Iris Korolkowi type with I. susiana and iberica, and also crosses between I. Korolkowi violacea with the purple-red I. Mariæ. Strange to say that a cross between I. Korolkowi concolor (which I find is not quite so vigorous as are the other Korolkowi varieties) with Iris Mariae—reputedly one of the most difficult of the Oncocyclus tribe—turned out a group of exceedingly vigorous varieties, of which the now well-known Artemis, a very bold flower with rich purple and violet-black coloured flowers, may stand as the type. Without going into cultural details, the fact that the stock of some of the varieties grown in my establishment, all, of course, propagated by division from single, selected specimens of special merit, in many cases now consist of several hundred plants, sufficiently shows that this race has come to stay in our gardens and not ultimately dwindle away, as will always do the pure Oncocyclus.

Naturally my attention also turned to the hybridising of the best varieties of the ordinary bearded Irises (germanica) with the Oncocyclus. A beautiful and very large flower came out of a cross between I. iberica and I. germanica macrantha, the flower measuring not less than 6

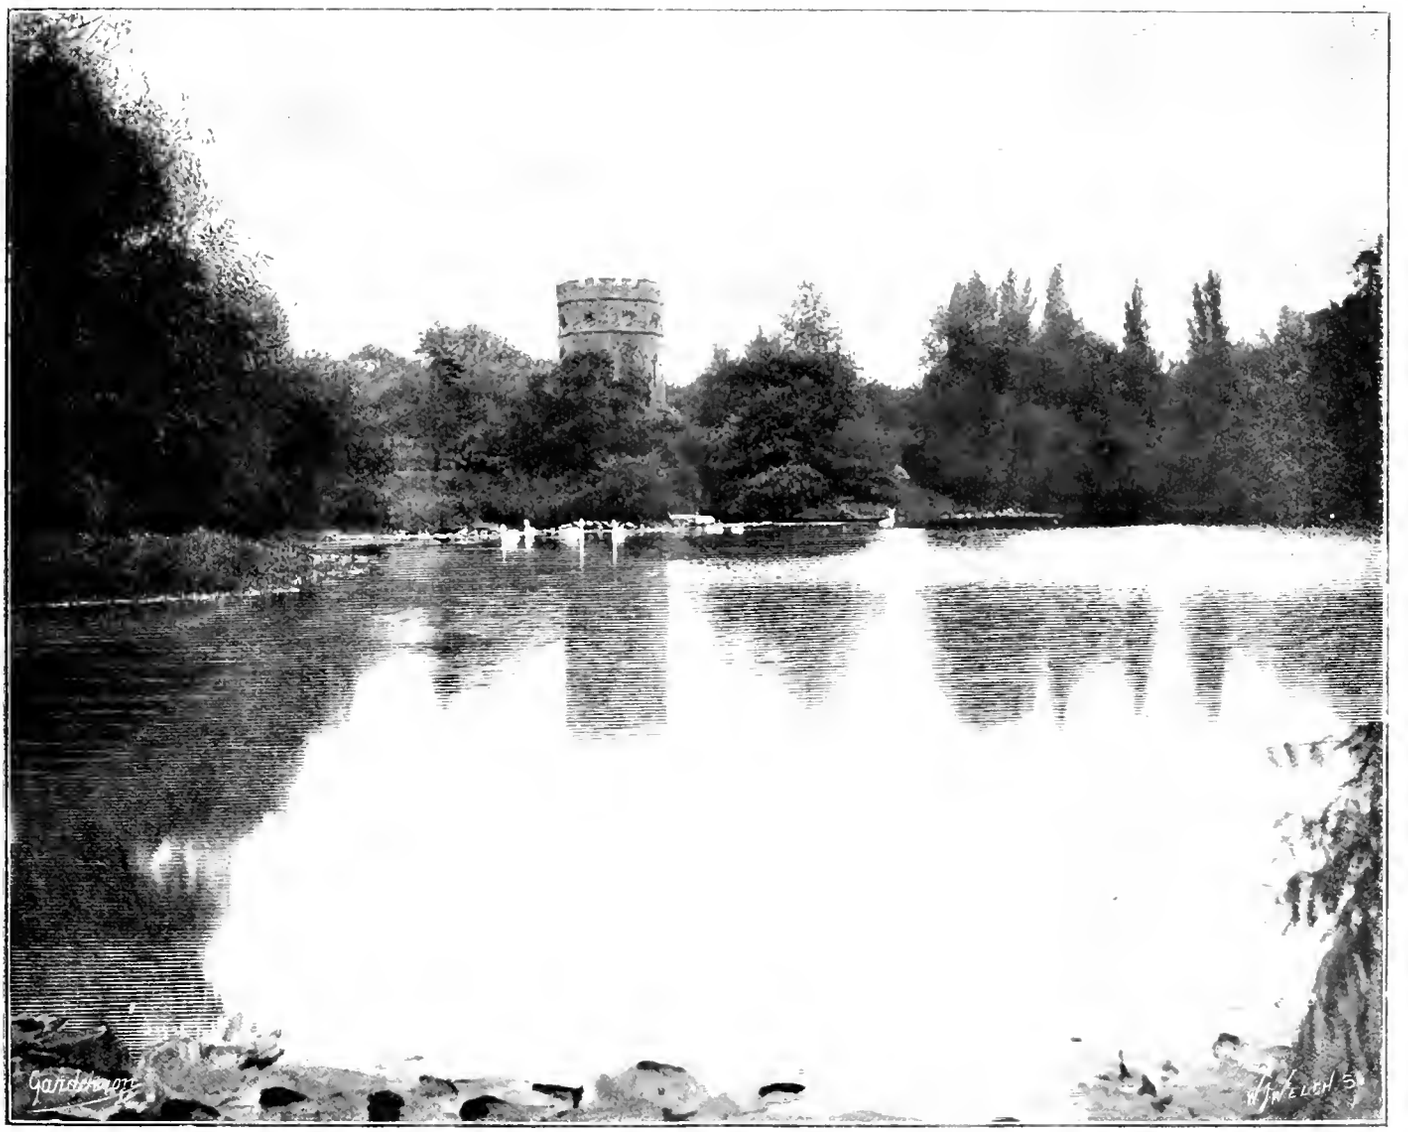

FIG. 51.—THE LOWER LAKE, GUNNERSBURY PARK.

(For text see page 121.)

inches across and of a beautiful blue, with broad, spreading falls, very hairy, and with a dark, black-blue central spot. Unfortunately in our climate, with its damp summers, we cannot give to these plants the dry, baking heat of southern countries, and the plants consequently are very shy-flowering, as are also similar crosses of Oncocyclus with pallida and germanica. Hybrids raised by Sir Michael Foster, however, among these groups, notably paradoxa and iberica crossed with I. variegata and sambucina, are almost as free-flowering as are the ordinary I. germanica.

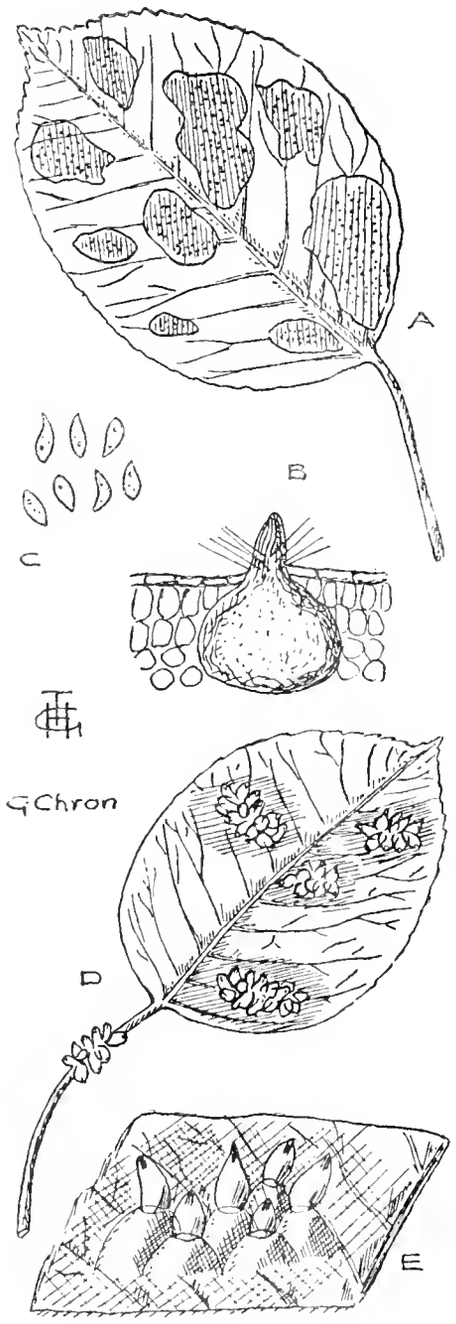

FIG. 52.

A. Pear leaf infested with rust. B. Section through a "spermogonium." C. Spores. D. & E. Æcidial form of the fungus.

Nerine.—Notable hybrids in this beautiful group of autumn-flowering bulbous plants arose from the intercrossing of Nerine pulchella with the best of other species and hybrids. I cannot understand why all the plants which were raised from this cross both ways developed a much later blooming character than either parents, so much so that they usually are about at their best the second and third week in December. These hybrids are very vigorous, with foliage 1½ to 2 feet in length and with flower-stems of corresponding height. The range of colours in these hybrids is from pale rose to bright carmine, and the umbels, composed of very numerous flowers, measure from 6 to 7 inches in diameter. Unfortunately these hybrids seem to be absolutely sterile, so that I fear it will be very difficult, if not impossible, to further develop this strain, which, even as it is now, proves very valuable for producing bright coloured effects in the cool conservatory at the dullest time of the year.

THE PEAR RUST (GYMNOSPORANGIUM SABINÆ).

The Pear rust fungus is not so frequently met with in this country as on the Continent, although the disease is from time to time recorded here.

My notice has been directed to a severe outbreak of this disease in Sussex, where it spread with such rapidity as to suggest that it will secure a firm hold in this country, if it be not arrested by timely measures.

The fungus makes its first appearance in June, manifesting itself by conspicuous red spots on the leaves (see Fig. 52, A). The spots on the upper surface of the leaves, when viewed through a pocket lens, will be seen to be covered with numerous raised pores (spermogonia) of a slightly darker colour. If a section be cut through one of these pores, it will be noticed, when placed under the microscope, to be a small "conceptacle" of the fungus, containing a great number of minute, irregularly-shaped spores (Fig. 52, B, C). It is generally considered that these spores perish after a short time, without any apparent injury; this, however, is a matter to be determined by further inquiry.

Towards August rather large yellowish pustules (known as æcidia), corresponding to the spots on the upper surface, appear on the lower surface (see Fig. 52, D, E). During September numerous spores are formed in the pustules, which, when ripe, are shed and freely carried about in the air. They cannot, however, germinate again on the Pear, and the destructive work of the fungus is terminated, unless it passes through another stage on an intermediary host, namely, bushes of various species of Juniperus such as Juniperus Sabina, J. virginica, and J. phœnicea, etc., all of which are frequently cultivated in gardens. When the "æcidia" on the Pear shed their spores and some fall on to a Juniper, the spores readily germinate on the young and tender shoots, permeating them with a fine spawn and producing a more or less pronounced swelling of the shoot. In the spring, at the time when the Pear leaves unfold, one can detect the fruiting stage of the fungus on the Juniper, which takes the form of large brownish projections around the swollen portions of the stem (see Fig. 53, F). During rain these absorb water, increase in size, and become gelatinous (see Fig. 53, G); the upper surface takes a yellowish tint, which becomes more pronounced as the spores (teleuto-spores) ripen. These latter spores again cannot germinate on the Juniper itself, but should they fall upon a Pear leaf the characteristic red spots, as described above, will make their appearance.

It is thus apparent that the fungus hibernates in the shoots of the Junipers. In consequence, if there are not any Juniper bushes in the neighbourhood, or if such be destroyed, the possibility of a re-appearance of the fungus in the next year is reduced to a minimum. It has been suggested that spraying with a solution composed of 4 lbs. of lime, 4 lbs. of sulphate of copper, and 50 gallons of water will kill the fungus on the Pear leaves. But in large orchards this method is impracticable, as the amount of labour would involve too great an expense, and it seems simple enough to destroy the Juniper bushes—provided, of course, that one is surrounded by obliging neighbours!

H. T. Gussow.

THE PROPAGATOR.

BUDDING.

DURING the month of August the budding of suitable stocks with Peaches, Pears, Nectarines, Plums, Apples, and Roses should be undertaken, either by means of thin shield-buds, with the wood left intact and placed on the shoots from which a corresponding slice has been removed, or in the usual way, with buds from well-matured shoots, from which the woody portion has been removed by an upward movement of the knife, being careful not to take away the base of the bud. Shoots from which buds are to be taken should be most carefully kept from the direct rays of the sun, and be immersed in a covered vessel containing water. In

FIG. 53.

F. Branchlet of Juniper with yellow jelly-like fungus (Gymnosporangium). G. The same enlarged.

the case of standard briar stocks, the insertion of one or two buds suffices to form a crown, doing this on the strongest shoot or shoots close down in the fork, and binding firmly with worsted or raffia.

Dwarf stocks of Manetti, Polyantha, or any other Rose stocks should be budded an inch or two below the ground in order that the bud, when grown, may put forth roots. Low-growing fruit stocks may be budded at about 9 inches above the soil, and the top growth of the stock left intact for a time. The stocks of the Rose, in the case of wildings, may be thinned of the small growths, and the vigorous shoots slightly topped, so as to lessen the chances of breakage by the wind.

Pears may be budded on the Quince, or, in the case of varieties which do not succeed when budded direct on to the Quince, on to some other variety of Pear that is itself on the Quince, the second budding being undertaken in the following month.

There are many ornamental trees and shrubs that may be budded. The present is also a suitable time for layering Carnations, Picotees, and Pinks in the open border, and in pots. In the case of the latter, a rim of zinc, tin, or flakes of thin roofing slate should be placed just within the rim, followed by a filling of sandy loam and leaf soil, the longer shoots being twisted round so as to be got well within the soil when "tongued" and pegged down. Root cuttings, 1, 2 and 3 inches long, of Clematis of the common Traveller's Joy, C. vitalba, or of fine varieties, may be put into pans of sandy soil; of Hellebores in variety, choosing, in the case of these plants, the thick roots, and inserting them in well-drained pans filled with sandy loam and leaf-mould, and affording bottom heat of 70°. Anemone japonica and its varieties, and A. blanda are similarly increased. Cuttings of the single-flowered red and white Camellias, when seeds are not available, may be struck this month in a sand bed having a warmth of 75°. These single-flowered varieties, that are so easily obtained from seed, come in usefully as stocks on which to graft ennobled varieties, and as floral objects in the greenhouse, for they flower with great freedom.

Zonal Pelargoniums for greenhouse decoration, and Fuchsias for early flowering next year, may now be struck, the former in frames or out-of-doors in the full sun in pots, or in the open ground, suitably prepared with sandy loam, and the latter from half-ripened shoots in small pots in a warm house. Cuttings of double-flowered Nasturtiums, which form such decorative objects as basket and balloon plants in early summer for the greenhouse and conservatory, should now be rooted in moderate warmth. The cuttings should be potted, when rooted and grown, in a cool house or pit. During this month cuttings of Phloxes, both shrubby and herbaceous, may be inserted on a shady border; Violas, Pansies, and Pentstemons, Violets of all varieties may all be rooted from soft growths, inserting the slips in sandy loam and leaf-mould in cold frames, and shading the frame with thin canvas or reed mats from the direct rays of the sun. Verbena cuttings, formed of the unflowered shoots, may be taken 2 to 3 inches long, denuded of the lower leaves so far as the cutting enters the sand layer, and inserted in well-drained 32 pots, filled to within an inch of the top with sandy loam and leaf-mould. The pots should be stood on a warm leaf bed, or disused Melon or Cucumber bed, in a close frame, and be carefully shaded. Roots will form in 14 days. Ventilation should be afforded early on fine dry mornings for the space of a quarter of an hour, or damping off will occur with disastrous consequences.

Miscellaneous.

Callistemons (most species), Eugenia apiculata (a good substitute for Myrtle in bouquet work), E. australis, E. sinensis, and E. Jambos (also propagated in the spring), Beaufortia sparsa and Melaleuca Leucadendron, and viridiflora may all be propagated now from cuttings of side-shoots taken with a "heel" of the old wood, and inserted in clean sand, or a mixture of one part peat, two parts sharp sand, in well-drained pots or deep pans. The cuttings should have their leaves removed for one-third of their length, and be inserted at that depth. They require much moisture, greenhouse warmth, and should be covered with bell glasses having a hole at the top. *F. M.*

WATER LILIES.

The splendid hybrid Nymphæas lately introduced by M. Latour-Marliac are not so widely known as they should be, yet they are of easy cultivation, being perfectly hardy, and requiring no broad lake or deep water to set off their beauties. They can be grown in the driest garden, or even on a balcony or a terrace, in a half-cask or tub of water about 18 inches deep, where they will, as a rule, flourish far better than when exposed to the dangers from water-rats, dogs, and waterfowl, which often injure them when planted in a pond.

Moreover, they prefer water of a depth of not more than 2 feet, as they need the full warmth of the summer sunshine, being hybrids between the tropical Water-lilies and those of Siberia and North America.

A cask which has contained paraffin can be sawn in two, thoroughly charred inside to remove all traces of the mineral oil, and sunk to the rim, if preferred, at the side of the lawn, or surrounded by rock-work covered with low Alpine plants; or hidden by pieces of virgin-cork, pot plants and creepers, on the balcony of a town house.

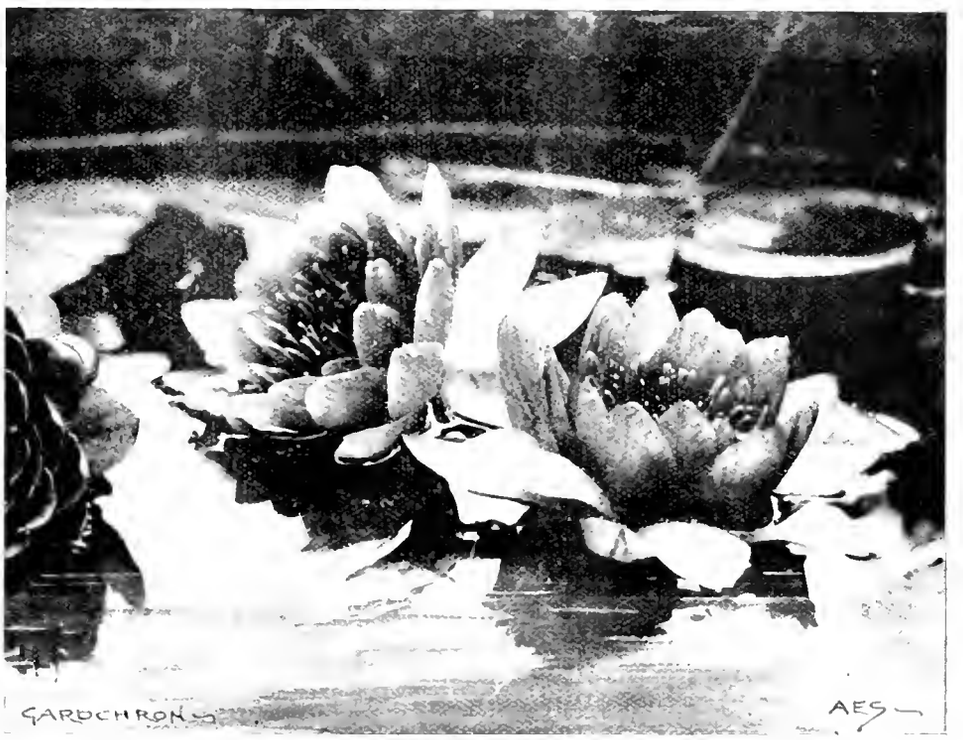

Fig. 54.—Nymphæa gloriosa: flowers rich crimson.

The Nymphæas chosen should each be planted separately in 6 inches of soil, which may consist of good loam and leaf-mould, without, however, any fresh manure, spreading out the roots horizontally and keeping them in place with a few stones. It is necessary to cover the roots thoroughly with soil, and the water can then be added from a rosed can, so as to avoid undue disturbance of the plants.

The water will remain muddy for a day or two, but if a few newts are then added to it, they will quickly clear it and keep it in proper order. Without animal life to balance the plant-life, water soon becomes turbid and sour, but these little creatures (Triton cristatus are thorough scavengers, and water in which they exist soon becomes clear. In this way all difficulties with regard to the cultivation of these fascinating flowers disappear. They bloom throughout the summer, producing a succession of buds until the winter cold sends them to rest.

The following is a list of the finest varieties: Nymphæa gloriosa, with blossoms 8 inches in diameter in the richest crimson; N. Paul Hariot, a pale pink Lily with a carmine centre; N. lucida, the star-like blooms of which are in salmon-pink, held 6 inches above the water; N. sulphurea grandiflora, with shaded yellow flowers; N. Vésuve, in brilliant red; and N. arc-en-ciel, with foliage shaded with carmine and apricot and blush-white blossoms. There are many others in various shades of pink, also very beautiful, but this half-dozen cannot be surpassed. *I. L. Richmond, F.R.H.S.*

THE UNITED STATES DEPARTMENT OF AGRICULTURE.

It is happily true that our own Board of Agriculture has of late years shown signs of progressive development, and Kew is, of course, in its way unique; but to show how much remains to be done, we give the following details concerning the working of the Agricultural Department in the United States. It will be seen that applied science rather than pure research is the main object aimed at.

"The law establishing the department, approved May 15, 1862, outlines the most important features of the work in the following provisions:

. . . the general design and duties of which (the Department of Agriculture) shall be to acquire and to diffuse among the people of the United States useful information on subjects connected with agriculture in the most general and comprehensive sense of that word, and to procure, propagate, and distribute among the people new and valuable seeds and plants. . .

The duties of the secretary are, among others, to acquire and preserve in his department all information concerning agriculture which he can obtain by means of books and correspondence and by practical and scientific experiments (accurate records of which experiments shall be kept in his office), by the collection of statistics, and by any other appropriate means within his power; to collect, as he may be able, new and valuable seeds and plants; to test by cultivation the value of such of them as may require such tests; to propagate such as may be worthy of propagation and to distribute them among agriculturists. He shall annually make a general report in writing of his acts to the President and to Congress, in which he may recommend the publication of papers forming parts of or accom-

panying his report, which report shall also contain an account of all moneys received and expended by him. He shall also make special reports on particular subjects whenever required to do so by the President or either House of Congress, or when he shall think the subject in his charge requires it.

Bureau of Plant Industry.

Pathologist and physiologist, and chief of bureau, B. T. Galloway; pathologist and physiologist, and acting chief of bureau in absence of chief, Albert F. Woods; editor, J. E. Rockwell; chief clerk, James E. Jones.

The Bureau of Plant Industry studies plant life in all its relations to agriculture. It includes vegetable, pathological, and physiological investigations; botanical investigations; farm management; pomological investigations; seed and plant introduction and distribution; the Arlington Experimental Farm; investigations in the agricultural economy of tropical and subtropical plants; drug and poisonous plant investigations; tea-culture investigations; dry land agriculture and Western agricultural extension; experimental gardens and grounds, and the seed laboratory.

Vegetable Pathological and Physiological Investigations.

Albert F. Woods, Pathologist and Physiologist.

These investigations have for their objects the study of diseases of agricultural crops and economic plants; nutrition of plants; rotation of crops; the general application of the principles of pathology and physiology to agriculture; the problems of crop improvement, and the production of better varieties of agricultural plants and of crops resistant to disease by means of breeding and selection. The work is conducted by the following officers: Erwin F. Smith, pathologist, in charge of Laboratory of Plant Pathology; Herbert J. Webber, physiologist, in charge of Laboratory of Plant Breeding; Walter T. Swingle, physiologist, in charge of Laboratory of Plant Life History; Newton B. Pierce, pathologist, in charge of Pacific Coast Laboratory; Hermann von Schrenk, expert, in charge of Mississippi Valley Laboratory; Peter H. Rolfs, pathologist, in charge of Subtropical Laboratory; Merton B. Waite, pathologist, in charge of investigations of diseases of orchard fruits; Mark Alfred Carleton, cerealist, in charge of Cereal Laboratory; C. O. Townsend, pathologist, in charge of sugar-beet investigations; William A. Orton, pathologist; W. M. Scott, pathologist; Joseph S. Chamberlain, physiological chemist; Thomas H. Kearney, physiologist; Cornelius L. Sneat, pathologist; Flora W. Patterson, mycologist.

Botanical Investigations.

Frederick V. Colville, Botanist.

This office maintains the economic herbarium, including the collections of useful native plants, weeds, cultivated plants and grasses; investigates the fibre plants of the United States, and is engaged in various other botanical investigations, including the preparation of a manual of the grasses of the United States, a flora of Alaska, and reports on the native plant resources of the country. The office includes Lester H. Dewey, botanist, in charge of fibre-plant investigations; A. S. Hitchcock, systematic agrostologist, in charge of botanical studies of grasses; W. F. Wight, botanist, in charge of Economic Herbarium; W. E. Safford, botanist, engaged in the preparation of reports on economic plants.

Pomological Investigations.

G. B. Brackett, Pomologist.

This branch of the bureau collects and distributes information in regard to the fruit interests of the United States; investigates the habits and peculiar qualities of fruits; their adaptability to various soils and climates and conditions of culture. It studies the methods of harvesting, handling, and storing fruits with a view to improving our own markets and extending them into foreign countries. It includes: William A. Taylor, pomologist, in charge of Field investigations; G. Harold Powell, pomologist, in charge of fruit transportation and storage investigations; H. P. Gould, assistant pomologist, in charge of fruit district investigations; George C. Husmann, pomologist, in charge of viticultural investigations.

Seed and Plant Introduction and Distribution.

A. J. Pieters, Botanist.

This office is charged with the purchase and distribution of valuable seeds and plants, including those allotted by law to Senators, Representatives and Delegates in Congress; also those secured for experimental work conducted in co-operation with the agricultural experiment stations and private experimenters in various parts of the country. The officers are: A. J. Pieters, botanist, in charge; W. W. Tracy, Sr., superintendent of testing gardens; David Fairchild, agricultural explorer; P. H. Dorsett, pathologist in charge of plant introduction garden; C. V. Piper, agrostologist; J. M. Westgate, assistant agrostologist; O. W. Barrett, plant introducer; J. E. W. Tracy, assistant superintendent of testing gardens; George W. Oliver, expert plant propagator.

Arlington Experimental Farm.

L. C. Corbett, Horticulturist.

The Arlington Farm, of which L. C. Corbett, horticulturist, is in charge, is the field laboratory at Washington for the Bureau of Plant Industry. Each office of the bureau carrying on field investigations from the city laboratories maintains experiment plats at the farm. At present the lines of work include truck-work investigations, nursery experiments, forage-plant experiments, pathological and physiological investigations, and cultural and variety tests with fruit.

Investigations in the Agricultural Economy of Tropical and Subtropical Plants.

O. F. Cook, Bionomist.

These investigations are a continuation of the studies in tropical agriculture, but the scope of the work has been enlarged so as to provide for a bionomic treatment of the numerous temperate and subtropical crop plants which were originally natives of tropical countries, such as Indian Corn, Cotton, Beans, Potatos, Tomatos, &c. Experiments are being conducted with weevil-resistant Central American varieties of cotton, and with varieties of corn adapted to special conditions of growth, as in the humid tropics or in arid regions. Coffee, rubber and cacao are the tropical products receiving principal attention. Assisting in this work are: G. N. Collins, assistant botanist; F. L. Lewton, scientific assistant; H. Pittier and John H. Kinsler, special agents.

Experimental Gardens and Grounds.

E. M. Byrnes, Superintendent.

This branch, under E. M. Byrnes, superintendent, is charged with the care and ornamentation of the parks surrounding the department buildings; with the duties connected with the conservatories and gardens, and with the testing and propagation of economic plants. It carries on investigations for the purpose of determining the best methods of improving the culture of plants under glass, and other lines of investigations connected with intensive horticulture.

Seed Laboratory.

Edgar Brown, Botanist.

The object of the work of the Seed Laboratory is to improve the quality of agricultural seeds. Samples submitted by farmers and others are tested for mechanical purity and germination. Public announcements are made of prevalent adulterations and general conditions of poor quality existing in the seed trade. The proper conditions for storage under varying climatic conditions are being worked out. The deterioration of grain in transit is being studied with a view to improving the present conditions. In co-operation with other offices of the bureau, Clover and Alfalfa seed is being produced which is adapted to particular localities.

Plant Analysis Laboratory.

C. C. Moore, Chief.

On July 1, 1904, this laboratory was established and charged with the investigation of the composition of fertilisers, in which work the laboratory will co-operate with the referees of the Association of Official Agricultural Chemists, studying methods of analysis of fertilisers and fertilising substances. Miscellaneous examinations of fertilisers are not made. The laboratory is also to investigate the constitution of plants and is authorised to collaborate with the Bureau of Plant Industry in the chemical investigation of problems in which the Bureau of Chemistry and the Bureau of Plant Industry are mutually interested.

Bureau of Entomology.

Entomologist and chief, L. O. Howard.

The Bureau of Entomology obtains and disseminates information regarding injurious insects affecting field crops, fruits, small fruits and truck crops, forests and forest products, and stored products; studies insects in relation to diseases of man and other animals, and as animal parasites; experiments with the introduction of beneficial insects, and with the fungous and other diseases of insects, and conducts experiments and tests with insecticides and insecticide machinery. It is further charged with the investigations in apiculture and sericulture. The information gained is disseminated in the form of bulletins and circulars. Much museum work is done in connection with the department of insects of the National Museum, and insects are identified for experiment stations and other public institutions and private individuals. The work of this bureau is organised under sections, among which are:—

Fruit Insect Investigations.

A. L. Quaintance, in charge of deciduous fruits; C. L. Marlatt, in charge of tropical fruits.

This field of inquiry includes the study of insect enemies of orchard fruits, and is also divided into subsections: (a) Investigations of the insect enemies of deciduous fruits, such as the Pear, Peach, Plum and Apple, as illustrated by work recently completed on the codling moth; (b) work on the insect enemies of Orange and other Citrus fruits, Olive, Fig, and other subtropical fruits.

Truck Crop and Small Fruit Insect Investigations.

F. H. Chittenden, in charge.

This field of investigation relates particularly to the insects affecting garden vegetables and small fruits, and is facilitated by the maintenance of a small plant in the department grounds for the experimental study of the insects affecting such crops. The enormous increase in truck farming and in the growth of small fruits in this country leads to constant demands for special information covering this field.

Insecticide and Insecticide Machinery Investigations.

C. L. Marlatt, in charge.

This section covers the entire field of practical experimentation with insecticides and insecticide machinery. A chemist working in co-operation with this bureau is detailed by the Bureau of Chemistry to take charge of the analyses and tests of new insecticides. Field operations and experiments are conducted on

growing trees and vegetables. The enormous increase in the employment of mineral oils as a means of destroying insects has led to a special investigation of this subject now in progress.

Investigations of Insects Affecting Shade Trees and Ornamental Plants.

(Under the immediate direction of the Entomologist, assisted by F. H. Chittenden.)

This constitutes a section separate from the investigations on the insect enemies of forests, and although some of the insects are identical the problem of how to deal with them is in most cases quite distinct. It includes the economic treatment of borers, tree defoliators, scales and aphides, as well as other insects that affect trees in public parks and in the streets of large cities. A number of insects of this class, importations from Europe, such as the leopard moth, gipsy moth, brown-tail moth, and imported willow curculio, are demanding more attention year by year. This section includes also investigation of insects affecting greenhouse and garden ornamental plants and trees.

Introduction of Foreign Beneficial Insects.

(Under the immediate direction of the Entomologist.)

Results of extraordinary value in the control of certain imported insect pests have been secured by the introduction of their natural enemies, and two or three notable successes have resulted in the annual saving of more than the cost of the Bureau of Entomology since its origin as a division. The introduction of enemies of the boll weevil and of the gypsy and brown-tail moths comes in this field. When such work is carried out by expert entomologists there need be no risk of introducing injurious forms, but if attempted by private individuals there is danger of the introduction of harmful species.

PROFESSOR ERICH TSCHERMAK

is well known among students of heredity for his valuable contributions to this subject. He had the distinction of being one of the few who independently discovered, by means of his own experiments, the regularity in the process of the hereditary transmission of characters; and simultaneously with Professors de Vries and Correns, he announced these observations, and the re-discovery of Mendel's forgotten papers in which the same principles were first made known. Professor Tschermak has followed up these first experiments with many others on Pisum, Phaseolus, Cereals, &c., and has taken a prominent part in the extension of the subject. He attended and made an important contribution to the recent Hybridisation Conference. He is now professor in the Vienna High School for Agriculture. He comes of a distinguished scientific family, his father being the veteran Professor of Mineralogy in Vienna.

NEW INVENTIONS.

Mr. Valentine Collins, of 58, Lowden Road, Lower Edmonton, sends for our inspection a flower-pot, with a small moveable zinc tray inserted on one side just above the drainage-hole. The value of this is doubtful. A similar tray inserted on an earthenware stand on which a pot may be placed is more likely to be of service in the case of plants grown on a window-sill and periodically drenched with water.

PLANT PORTRAITS.

Apple Kruger's Dickstiel, so named from its thick fleshy stalk. Fruit of medium size, ovoid conic, yellow, red on the sunny side; flesh white, delicate, sweet and vinous in flavour, November to March. L. Spath in *Garten Flora*, tab. 1,553, August.

Iris Lorteti.—*Revue de l'Horticulture Belge*, August 1.

Jasminum nitidum.—*Revue de l'Horticulture Belge*, August 1.

HOME CORRESPONDENCE.

The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

Sutton's Evergreen Dwarf Bean.—This is undoubtedly a very fine acquisition among vegetables. It is the heaviest cropping dwarf variety that I know; the plants are laden with pods. From a row consisting of about 30 plants, placed 6 inches apart, when they were allowed to remain ungathered for a week after a first picking, no less than 10 lbs. weight of excellent pods were gathered. Providing the flowers set readily under artificial conditions it should prove a valuable variety for forcing. *G. H. Head, Kingsdon Manor Gardens, Taunton.*

Late Strawberry.—Undoubtedly the best late Strawberry is Givon's Late Prolific, which comes into full bearing after Royal Sovereign, President, and Sir Joseph Paxton have finished. If but two varieties are required for all purposes, Royal Sovereign and Givon's Late Prolific will furnish a supply from the middle of June until the beginning of August. The habit of growth of the latter is compact, the trusses of fruit being carried well above the foliage. If late fruit is in demand, it will repay for extra labour entailed. At the time of writing, August 2, good sized and excellently flavoured fruits are being gathered daily. *S. E., Lavington Park.*

Prof. Tschermak.

Blackberries. The Blackberry crop for 1906 should eventually prove one of the heaviest known. Never before has there been such a set; it is so thick that everywhere the brambles are loaded. It needs but a good soaking rain to ensure a crop almost phenomenal in amount. Rain is badly needed throughout the district. *H. R., Maidstone, August 11, 1906.*

Weather and Fruit Crops in N.W. of Scotland.—Now that the season is far enough advanced to form a fair idea of what the crops will be like, it may be of value to compare it with other seasons and other places. January was, on the whole, a good winter month for the district, mild days alternating with frost, rain and some snow. The weather in February was, however, bad, for we experienced heavy snowstorms and hard frost, and had the most severe snowstorm that has been known in the district for 11 years past, the mail-coach roads being completely blocked for weeks. March was a cold, wet month. Two weeks in April were abnormally warm for the time of year, but the following weeks until the beginning of July were dull, with a low temperature, so that no growth was made, consequently everything is very late. Peas sown in the middle of March are only now ready for use. Cauliflowers sown in heat on January 30, and afterwards pricked into boxes before being planted out, are just beginning to "turn in." The following remarks concern the fruit crop. The Apple yield is below average, some trees having none, others have an average crop. Pears are not grown outside. Plums are below the average. Of Cherries there have been none, when in bloom most of the trees had nothing but a calyx, being quite destitute of stamens and pistil. Apricots, Peaches, and Nectarines are not grown outside. Small fruits are an average crop and good, Strawberries under an average yield and of bad quality. To sum up, it is the latest and the worst season I can remember. *Harry Low, Blackmore Gardens, Garve, Ross-shire, N.B.*

Two Cape Plants now in Season.—I recently saw at a country village flower-show two Cape plants which are worthy of more attention than is generally bestowed upon them. Both were exhibited in the cut state, and were much admired. One was the beautifully chaste Watsonia Ardernei; the other Gladiolus psittacinus. The Watsonia was not so good as it might have been, owing probably to the cultural details being insufficiently understood, for although its culture is quite simple a little neglect or misunderstanding will cause a complete failure, and render the plant unpopular. When better known there surely is a great future for this flower. The Gladiolus was exhibited in a vase containing spikes of G. Brenchleyensis, and made a delightful contrast. The bright yellow of the falls and the yellow splashes in the brilliant hood caused the flower to find many admirers. This Gladiolus is, I believe, the parent of G. Brenchleyensis and Gandavensis. *H. R., Maidstone, August 11, 1906.*

Catalpas in Flower.—In the column headed "London Day by Day," of the *Daily Telegraph* of the 9th inst., I notice the following:—"This year the show of the handsome bloom of Catalpa bignonioides . . . . is disappointingly very sparse in the London district. The parent tree in this country—traditionally said to have been planted by Lord Bacon in Gray's Inn Gardens—has not a single flower." Not having seen the specimen this season, I cannot remark upon its floral condition, but Mr. H. S. Martin writes on the following day to the same paper, stating that there is a tree "covered with magnificent bloom" at Winchmore Hill, N. The tree in our own garden is also flowering well; in fact, better than in former years. The association with Lord Bacon can only be "traditional," Catalpa bignonioides (or syringæfolia) having been first introduced from America in 1726, whereas the great statesman died in 1625. That Lord Bacon planted a tree exactly 100 years after his death is, doubtless, one of the many popular errors kept up by tradition. *Lionel A. de B. Crawshay, Rosefield, Sevenoaks, August 13, 1906.*

Lastrea montana var. truncata. Recently at Thirlmere, on the flank of Helvellyn, I found two plants of this curious variety, in which the frond ends abruptly and squarely, at about two-thirds of the normal length, with the midrib projecting about half an inch and ending in a sharp point, while all the side divisions or pinna end equally abruptly with minute pointed projections. The frond forms thus an oblong parallelogram tapering, however, somewhat to the base instead of being lanceolate or spear head shaped. A curious fact is that though this form of variation is by no means common in Ferns, it occurs so frequently in this particular species that among the Fern hunters of the lake district it is termed the "beginner's Fern" since its frequent occurrence and prominent character make it so easy of recognition. A further remarkable fact, however, is that this peculiarity is exactly imitated in the damage caused to young normal fronds by some insect, which appears to have a temporary domicile in the coiled up tips, and by devouring the growing points symmetrically causes the subsequent development to assume a truncate form quite indistinguishable superficially from the true truncate variation. On close examination, however, it may be seen that the thorn-like projections are absent, and on examination with a lens a minute brown scale at the tip may be seen on the terminations of the main and secondary midribs; such fronds also only occur singly and in association with normal ones on the same plant. This, however, by itself is no criterion of imitative truncation by damage, since single fronds of the true truncate and thorned condition often occur on otherwise normal plants. The damaged fronds are so frequent in some localities as to suggest that the true truncate varieties are due to inheritance of the thus acquired form, a theory which I do not credit for a moment, though the association is the more striking since we know of no parallel case in other species. *L. montana* I have found on several occasions at Aberfeldy, Abertoyle, Strathblane, and elsewhere in Scotland, and, as I have said, it occurs frequently in the English lake district. *C. F. Drury.*

SOCIETIES.

ROYAL HORTICULTURAL.

AUGUST 14.—The displays at the meeting held on this date formed a very pleasing show, for the Hall was well furnished with exhibits, and many visitors expressed surprise that such a good exhibition should be found at this season. Groups of Orchids and other flowers were finely shown, and there were also some meritorious exhibits of fruit. A collection of Gladioli was staged of remarkable quality. Hardy flowers were again a prominent feature, and one very large group was composed entirely of showy annuals. That autumn is approaching was evidenced by a beautiful exhibit of Dahlias from the open Each of the committees granted awards to novelties, although not so many as is generally the case. The FLORAL COMMITTEE gave five Awards of Merit, the ORCHID COMMITTEE one Award of Merit to a big-lipped Cypripedium, and the FRUIT & VEGETABLE COMMITTEE raised the award to the culinary Pea "Sweet Content" that was figured on p. 98 from an Award of Merit to a First-Class Certificate. At the meeting of the Fellows in the afternoon 22 new members were added to the roll of the society.

Floral Committee.

Present: W. Marshall, Esq. (Chairman), and Messrs. C. T. Druery, H. B. May, T. W. Turner, J. F. McLeod, J. W. Barr, George Gordon, J. T. Bennett Pöe, Wm. Howe, C. R. Fielder, Chas. Jeffries, Herbert J. Cutbush, Charles Dixon, Chas. E. Pearson, Chas. E. Shea, W. P. Thomson, E. H. Jenkins, W. J. James, George Paul, James Walker and Geo. Nicholson.

The biggest group of plants in the Hall was put up by Mr. Kelf (gr. to Miss ADAMSON, Regent's Park, London). The exhibit almost filled one side of the building, and it was arranged on the ground against the wall. Tall Palms formed a background for masses of Caladiums, Dieffenbachias, Begonia Rex, and other ornamental-leaved subjects, among which were interspersed flowering plants—Agapanthus umbellatus, Plumbago capensis, Celosias, &c. All the plants looked remarkably healthy, especially when it is considered they were grown so near to the heart of London. (Silver Gilt Banksian Medal.)

Messrs. KELWAY & SON, Langport, Somerset, showed spikes of Gladioli in their usual superb style. No fewer than 180 distinct varieties were displayed in the exhibit, including several new varieties; four of the best of these are described under Awards. To attempt a description of the more beautiful would be a difficult task, for each kind appeared as charming as its neighbour. We can only state that they represented the very best shades of colours, and each showed fullness of flower and large, bold spikes. (Silver Gilt Flora Medal.)

Messrs. WEBB & BRAND, The Nurseries, Saffron Walden, showed Hollyhocks, of which flowers they are noted growers. All were double varieties, and each had a very full centre, set off by a collar-like row of outer guard-petals. Miss Lizzie King represents their newest variety, the colour being a good deep shade of yellow. As a selection of the best kinds we may name Peri (cream), Salmon Queen, Black Knight (very dark, verging on black), James Allen (mulberry), and Walden Primrose. (Silver Flora Medal.)

Mr. GEO PAUL, The Old Nurseries, Cheshunt, had sprays of many interesting plants. Pavia macrostachya has trusses of white flowers, with very long stamens, that are tipped with small, red-coloured anthers. Tamarix æstivalis produces long, feathery plumes of bright rose-coloured flowers. The Rose Acacia Bessoniana has stems covered with red spiney hairs; the corolla is also hairy. Many ornamental leaved trees were shown, of which we may mention the large-leaved Lime Tilia americana latifolia, and Catalpa purpurea, the latter being in flower. Other interesting things were Aronia floribunda—in fruit—Calycanthus occidentalis, and Amorpha canescens.

Messrs. WM. ARTINDALE & SON, The Nurseries, Nether Green, Sheffield, filled one of the large central tables with varieties of Fuchsias. The flowers were not in the best condition, and the blooms bore evidences of injury in transit. Large double white varieties were prominent. Theroigne de Mericourt has very large white flowers, with a suffusion of pink. Sylvia is also a double white flower, the bells being very long and very freely produced. Alice Hoffman is a pleasing "bedder." It is fine in habit, and has a bright rosy calyx over a corolla of pure white. Messrs. ARTINDALE also exhibited a batch of Pentstemons. (Silver Banksian Medal.)

Dahlias from the open, the first display of the season, were admirably shown by Mr. S. MORTIMER, Rowledge, Farnham, Surrey. He had both Cactus and show varieties. Gaiety—a suffusion of rose in yellow—Imperial—imperial suggests the shade of purple—Earl of Ravensworth, and Warrior (scarlet) are four splendid show varieties. Among the Cactus type were seen most of last season's acquisitions and standard varieties. (Silver Flora Medal.)

Messrs. GUNN & SONS, Market Hall, Birmingham, displayed a very large assortment of border Phloxes. The beautiful white Fiancée attracted attention. Sheriff Ivory is also one of the best kinds; the colour is salmon pink, with a deeper-coloured eye. Sylphide is, perhaps, the best white Phlox: this was also shown well. Etna (scarlet), Dame de Beauté (pale mauve), and Josephine Gerbaux are other first-class kinds. (Silver Gilt Banksian Medal.)

Messrs. H. CANNELL & SONS, Swanley, Kent, staged a fine assortment of hardy flowers, nearly all of which were annuals. They showed China Asters in all the best varieties, Sweet Sultans, the gorgeous Salpiglossis in many tints, Lavateras, Zinnias, border Pinks, Scabiosa grandiflora, Calliopsis, Rudbeckias, and a host of other pretty things. Specially meritorious were varieties of Antirrhinums, Fire King (fiery orange), Defiance (deep orange), and Brilliant Rose being remarkably fine. (Silver Gilt Flora Medal.)

Messrs. BARR & SONS, King Street, Covent Garden, London, showed a selection of border flowers, such as garden Phloxes, Kniphofias, Gladioli, Gaillardias, Liliums, Rudbeckias, and other seasonable Composites, Statice, &c. A double form of Gypsophila paniculata is a useful flower for decorative purposes. Pans of brilliantly-coloured Nymphæas were arranged along the front of the exhibit. (Bronze Flora Medal.)

Mr. AMOS PERRY, Enfield and Winchmore Hill, London, N., staged 27 distinct varieties of hardy Nymphæas. Among new varieties William Doogue has large creamy-white flowers, with a suspicion of rose, the petals being well set off by the yellow centre of stamens; James Gurney is a medium-sized claret-coloured flower; and a small kind named N. Leydekeri rosea prolifera. The varietal names are descriptive of the flower, the colour being rose, and the two-dozen flowers exhibited were, with others, gathered from one plant. At the back of the Nymphæas was an array of border flowers. A nice batch of Asclepias tuberosa furnished a pleasing effect of colour. The floriferous Physostegia virginica, showy spikes of Liatris pycnostachya, Phloxes, Gaillardias, &c., were relieved with ornamental Rushes and Grasses. (Silver Banksian Medal.)

Messrs. R. WALLACE & Co., Kilnfield Gardens, Colchester, showed border flowers in variety. We noticed some improved kinds of Montbretias, Westwick being one of the best. Hardy Nymphæas in many choice varieties—N. tuberosa rosea has fragrance in addition to beauty—Phloxes, Liliums, Gladioli, rose-shaded Lupins, &c., are some of the principal subjects displayed. (Silver Banksian Medal.)

Mr. MAURICE PRICHARD, Christchurch, Hants., showed garden flowers in great variety. In the centre of the group were a number of Kniphofias. Scabiosa caucasica, Crinum Powelli, Hemerocallis Dr. Regel, an assortment of Gladioli, &c., were seen with others of equal beauty. (Silver Flora Medal.)

Messrs. THOS. S. WARE, LTD., Ware's Nurseries, Feltham, Middlesex, staged a nice array of border flowers, the group having as an edging vases of Cactus Dahlias and sprays of Statice profusa. Phloxes, Carnations, Scabiosas, Pinks, Delphiniums, Aconitums, Pentstemons, &c., were all well shown. (Silver Flora Medal.)

The Misses HOPKINS, Mere, Knutsford, staged a small collection of border flowers and Alpine plants.

Messrs. WM. CUTBUSH & SON, Highgate, London, N., showed vases of the large white Chrysanthemum maximum "The Speaker," and others of Carnations, with pot plants of Souvenir de la Malmaison varieties.

Messrs. HUGH LOW & Co., Bush Hill Park, Enfield, exhibited a batch of the old Cassia corymbosa, their new Smilax (Asparagus medeoloides) and a few other plants.

Mrs. STANTON, Child's Hill, London, N.W., showed a very large plant of Nephrolepis in a small hanging basket.

A new pink-coloured border Carnation was shown by CLAUDE WATNEY, Esq., Garston Manor, Watford (gr. Mr. Dyke).

Mr. JOHN COOPER, Hardy Plant Nursery, Chipping Norton, showed a shapely Carnation named Roy Morris—the colour is rich scarlet. Another named Mrs. J. Cooper is flesh or pale-pink colour.

Messrs. JAMES CARTER & Co., High Holborn, London, showed dwarf Antirrhinums and double-flowering Hollyhocks.

Messrs. WM. BULL & SONS, King's Road, Chelsea, S.W., displayed ornamental foliage plants suitable for stove and greehouse decoration.

AWARDS OF MERIT.

Rose Gottfried Keller.—A single variety of the Austrian Briar type, with exquisitely-tinted petals. It was raised by M. Fröebel, of Zurich, the parents being Austrian Briar and a Tea variety. The flowers more resemble those of the Briar, the Tea blood being more apparent in the wood and foliage. The petals are a soft rose-pink shade in their upper parts, merging to a yellow centre. The flowers show a slight tendency to doubling. They are very freely produced, and a succession is maintained through the season. Shown by Mr. GEO. PAUL, Cheshunt.

Gladiolus Mrs. Cecil Baring.—A very large flower of pale sulphur or lemon shade, with a remarkable lower petal that forms a distinct lip. This is coloured at its extreme end of a sulphur yellow, and passes to a canary yellow shade, and behind this it is densely spotted with bright red. The uppermost petal is very reflexed. The spike is tall, the flower-bearing portion being 18 inches to 2 feet long.

G. White Knight.—A very bold flower with massive white petals, the lower ones showing traces of rose-coloured guiding lines. The stamens are pale lavender coloured.

Golden Ray.—A variety showing a desirable break in colour, approaching yellow. The lip has an orange-coloured blotch, with carmine stripes running through it. The flowers are somewhat hooded in the young state.

G. Mrs. Coddington.—A flower of remarkably pleasing shape, and one having exquisite colouring. The two lower petals of the inner whorl are heavily marked with violet carmine, on the outside of which is a splash of yellow. The upper petals are suffused and dotted with rose.

The four Gladioli shown by Messrs. KELWAY & SONS.

Orchid Committee.

Present: Harry J. Veitch, Esq., in the Chair, and Messrs. Jas. O'Brien (hon. sec.), J. W. Odell, H. A. Tracy, W. H. Young, W. H. White, H. G. Morris, Arthur Dye, Walter Cobb, R. G. Thwaites, W. Boxall, G. F. Moore, F. Menteith Ogilvie, T. W. Bond, and Major G. L. Holford, C.I.E., C.V.O.

For the time of year there was a very fine show of Orchids.

Messrs. SANDER & SONS, St. Albans, were awarded a Silver Flora Medal for an effective group, in which the main feature was a selection of their fine strain of Lælio-Cattleya bletchleyensis, whose flowers, always fine, exhibit considerable variation in colour, most of them being rosy-lilac with large purple labellums. One distinct form had pale yellowish sepals, and petals with lilac tint in the veining, and a reddish-purple lip. The group was completed with good forms of Cattleya Warscewiczii, Odontoglossum ramosissimum, Dendrobium Phalænopsis, Brasso-Lælio-Cattleya Mackayi, a nice plant of Odontoglossum bictonense album, Aerides Lawrenceanum, Cattleya Lord Rothschild, Theodora gomesioides, Epidendrum Medusæ, &c.

Messrs. CHARLESWORTH & Co., Heaton, Bradford, secured a Silver Flora Medal for a very interesting group in which several forms of their splendid type of Odontoglossum Rolfeæ were displayed. The flowers of all were large and finely formed, the ground colour varying from white to primrose, and with showy purple mark-

ings. Two spotted forms of O. crispum; a plant of the dwarf Oncidium macranthum nanum, which never produces a long trailing spike; a very fine Miltonia Schröderiana, several of the pretty Anaectochilus Thompsoni var. Gentilii, Lælio-Cattleya Berthe Fournier, several good L.-C. callistoglossa, L.-C. Issy, Cattleya Vulcan, C. Gaskelliana alba, C. calummata nobilior, C. Lord Rothschild, and various hybrid Cypripediums, &c., were also included.

R. I. Measures, Esq., Cambridge Lodge, Camberwell (gr. Mr. Smith), staged a group in which were varieties of Cattleya Warscewiczii, Lælio-Cattleya Remula, and various hybrid Cypripediums, of which C. Wottoni was the best. Species and varieties were represented by Saccolabium ampullaceum, Masdevallia Carderi, and other Masdevallias, Scaphosepalum pulvinare, Pleurothallis scapha, and other Pleurothallis, Brassia Keiliana, Cælogyne Massangeana, &c. (Silver Banksian Medal.)

Messrs. Hugh Low & Co., Enfield, staged a neat group in which were several good Cattleya Gaskelliana, C. bicolor Grossii, C. granulosa, Catasetum macrocarpum, Mormodes pardinum unicolor of a clean yellow tint; the rare and pretty reddish-yellow Epidendrum pristes, Dendrobium Dearei, Oncidium carthaginense, &c. (Silver Banksian Medal.)

Messrs. Stanley & Co., Southgate, arranged an effective group, in the centre of which was a batch of Oncidium varicosum, having in front a number of good plants of Cypripedium A. de Lairesse and at each side good examples of Lælia crispa. The group was completed with Cattleya Harrisoniana, Odontoglossum crispum, O. Harryanum, O. Hunnewellianum, Dendrobium Phalænopsis, Lælio-Cattleya elegans, and various hybrid Orchids. (Silver Banksian Medal.)

Sir Trevor Lawrence, Bart., Burford (gr. Mr. W. H. White), sent an interesting collection of rare Orchids, including a grand specimen of Platyclinis filiformis, Cycnoches Egertonianum viride, C. maculatum, Catasetum fimbriatum and its variety platypterum, two pretty specimens of the floriferous Odontoglossum aspidorhinum, Dendrobium glomeratum, and the rare Oncidium panduratum.

J. Gurney Fowler, Esq., Glebelands, South Woodford (gr. Mr. J. Davis), sent the very fine rose-purple tinted Cattleya Warriniana, "Fowler's variety," with a strong spike of six large flowers; two forms of Lælio-Cattleya elegans; the dark coloured Cypripedium Bingleyense var. Æneas, and C. Penelope (Morganiæ × superbiens).

Jeremiah Colman, Esq., Gatton Park, showed fine varieties of Lælio-Cattleya bletchleyensis, L.-C. Nyssa, L.-C. Phryne, L.-C. Atalanta, and L.-C. elegans Schröderiana.

C. J. Lucas, Esq., Warnham Court, Horsham (gr. Mr. Duncan), staged a small group of his Lælio-Cattleya Geoffrey (L. Lucasiana × C. Warscewiczii). The flowers are formed like those of a small L. Jongheana, with an elongated crimped lip. Sepals and petals pale lilac, base of the lip white to yellow, front and margin purple. Mr. Lucas also showed L.-C. Lucasi (L. Iona × C. Warscewiczii), a pretty flower somewhat resembling L.-C. Ingrami, and various hybrid Cypripediums.

F. Ducane Godman, Esq., Horsham (gr. Mr. Moody), sent a specimen of Satyrium carneum.

M. Jules Hye de Crom, Ghent, sent a small plant of Miltonia Hyeana (M. Bleuana × M. vexillaria Leopoldi). Flower white with faint rose mark in centre and yellowish mark at base of lip.

AWARDS.

Award of Merit

To *Cypripedium Harri-Leeanum, Park Lodge variety* (Harrisianum superbum × Leeanum), from E. Roberts, Esq., Park Lodge, Eltham (gr. Mr. W. Carr). A very fine massive and dark-coloured hybrid. Dorsal sepal large and bearing many feathered blackish lines and a bright rose tint extending to the clear white margin. Petals and lip broad and heavily tinged with reddish-purple.

Botanical Certificate.

Cycnoches Egertonianum viride, from Sir Trevor Lawrence, Bart. (gr. Mr. W. H. White). A singular species bearing a long raceme of pale green flowers.

Cultural Commendations.

To Mr. H. G. Alexander (Orchid grower to Major G. L. Holford, C.I.E., C.V.O.) for the inflorescence of a noble plant of Odontoglossum crispo-Harryanum. The two spikes, coming from one bulb, were 5 feet 6 inches long, one bearing 24, and the other, with 11 branches, 49 flowers.

To Mr. W. H. White (Orchid grower to Sir Trevor Lawrence, Bart.) for a noble specimen of Platyclinis filiformis with about 100 spikes.

Diploma Awards.

Lælio-Cattleya elegans and Hybrids.—*1st Diploma.*—L.-C. Berthe Fournier, from Messrs. Charlesworth & Co. *2nd Diploma.*—L.-C. elegans Turneri, from J. Gurney Fowler, Esq. (gr. Mr. J. Davis).

Cattleya Warscewiczii and Hybrids.—*1st Diploma.*—L.-C. Nysa gloriosa; *2nd Diploma.*—L.-C. bletchleyensis, both from Jeremiah Colman, Esq. (gr. Mr. W. P. Bound).

Fruit and Vegetable Committee.

Present: Geo. Bunyard, Esq. (chairman), and Messrs. Jos. Cheal, Henry Parr, S. Mortimer, Wm. Pope, R. Lye, Edwin Beckett, H. Markham, Horace J. Wright, Geo. Kelf, Joseph W. Davis, F. L. Lane, C. Foster, J. Jaques, and Owen Thomas.

Miss Adamson, South Villa, Regent's Park, London, exhibited a number of pot fruit trees, and dishes of various indoor fruits. Apple, Pear and Plum trees were in pots, most of which were bearing freely, and there were also bunches of Black Hambro, Muscat of Alexandria and Foster's Seedling Grapes cut from pot vines, with dishes of Plums, Kirke's Seedling, Jefferson (a good dish), Reine Claude du Comte Atthems, and others, Early Rivers' Nectarine, Brown Turkey Figs, Gooseberries in variety, Clapp's Favourite Pears, and other fruits. (Hogg Memorial Medal.)

Messrs. S. Spooner & Sons, Hounslow Nurseries, Hounslow, Middlesex, showed a dozen varieties of early culinary and dessert Apples. A finely-coloured sample of Lady Sudeley was included, also Goodenough's Nonsuch—a shapely fruit, of medium size, and with a pleasing eye. It had the appearance of a solid fleshed variety. Beauty of Bath, Pott's Seedling, Lord Grosvenor and Red Quarrenden are others that were prominent. (Silver Banksian Medal.)

Mr. S. Lawson, garden superintendent, Horticultural College, Swanley, showed bunches of Muscat of Alexandria and Canon Hall Muscat Grapes and dishes of Peaches, Sea Eagle, Mr. Gladstone and Princess of Wales, all of first-class quality. (Silver-Gilt Banksian Medal.)

Leopold de Rothschild, Esq., Gunnersbury Park, Acton, W. (gr. Mr. G. Reynolds), showed eight varieties of Peaches, all of magnificent quality—Sea Eagle, Albatross, Princess of Wales, Gladstone, Warburton Admirable, Barrington, and others. (Silver-Gilt Knightian Medal.)

Mrs. F. A. Brace, Doveridge Hall, near Derby (gr. Mr. G. Wadeson), showed a collection of hothouse fruits, Grapes, Melons, Nectarines, Cherries, Peaches, Figs, &c. The half-dozen bunches of Madresfield Court Grapes had nicely finished berries. (Silver-Gilt Banksian Medal.)

Messrs. Hugh Low & Co., Bush Hill Park, Enfield, London, N., showed well-fruited trees of Brown Turkey and Brunswick Figs.

Awards.

Culinary Pea "Quite Content."—This variety had previously received an Award of Merit, and is described and figured on p. 56. The Committee raised the award to a First Class Certificate. Shown by Mr. Edwin Beckett, Aldenham House Gardens.

NEWBURY HORTICULTURAL.

August 6.—For close on sixty years this Society has held an annual flower show, and the 58th, held on this date, was equal, and in some respects superior, to the previous ones. The weather was delightful, and the attendance a record one. The show was held in the grounds of Goldwell Park, kindly lent by F. R. Wilson, Esq. The park, being situated on rising ground and bordered by grand old trees, is an ideal spot for the display. Superior quality obtained in many of the exhibits, the groups were more numerous than on previous occasions, there being six, and all were good.

Plants.—The leading position in the group classes was taken by Mr. J. Lye (gr. to J. Liddell, Esq., Sydmonton Court), and although he had fewer plants than his competitors, they were more beautifully arranged. Mr. J. Howard was a good second, and the veteran Mr. C. Ross, Welford Park Gardens, was third.

In the class for greenhouse plants Mr. T. Surman (gr. to M. H. Best, Esq., Donnington Grove) had the only collection, the class being one of the weakest in the show, but large plants are now not much grown. For foliage plants Mr. J. Howard (gr. to Lady Sutton, Benham Park) was well to the front, Mr. Ross being awarded 2nd place. For Exotic Ferns, Messrs. Howard and F. Lock (gr. to G. F. Plevins, Esq., Tile Barn) won in the order named. Coleus were well shown, Messrs. Surman and Johnson taking the 1st and 2nd prizes respectively. Fuchsias were superb; indeed, they are always a feature at Newbury, for, though somewhat small, they were otherwise perfect specimens. Mr. T. Surman had the best plants, Mr. P. Mara (gr. to Sir A. Arbuthnot, Newtown House) being 2nd. Messrs. Surman and Howard had the best specimen plants in bloom, and Messrs. W. R. Cox and C. Ross the best foliage plants.

Table decorations, though less extensive here than at some shows, formed an attractive feature. Miss F. Harrold took the 1st prize, her table being furnished with Carnation Raby Castle; 2nd, Miss L. Harrold, with an arrangement of yellow and white Iceland Poppies. Mrs. T. Mercer had the best bouquet; Mrs. H. W. Parker and Miss Knight showed the best flower sprays and buttonholes.

Cut flowers in the open classes occupied much table space. Strong competition was seen in the class for a collection of 24 bunches. The 1st prize went to W. St. J. Leng, Esq., Welford Park (gr. Mr. Randall), whose flowers were beautifully arranged; 2nd, Mr. D. Bosley. Displays of Roses were excellent. Messrs. Jefferies & Son, Cirencester, were easily 1st; 2nd, Messrs. Cooling & Son, Bath. In the amateurs' class Mr. A. Galt (gr. to C. E. Keyser, Esq., Aldermaston Court) won the 1st prize; Messrs. Cox and Smith taking the 2nd and 3rd prizes in the order named. Messrs. Cox, Galt, and Smith had the best Sweet Peas; and Miss B. Frost the best bridal bouquet. Mr. J. R. Tranter, Henley, won in the class for Dahlias; while Mr. Newman had the best Carnations. The classes for amateurs, mechanics and artizans were well contested. Indeed, in many cases the hardy fruits and vegetables were equal to those in the open classes.

Fruit occupied much space. There was a lack of collections, but a splendid lot came from Mr. J. Howard, Benham Park, he having beautifully-finished Grapes, Peaches, Nectarines, Melons, and Apricots. The same exhibitor had the best Pineapple. Mr. T. Surman showed the premier black Grapes; Mr. A. Ross the best Muscat of Alexandria; while Mr. T. Surman won for any other variety of Grapes. Mr. Galt was 1st for Melons, and Mr. Lock led in the class for Peaches; while for Nectarines, Dessert Apples, Culinary Apples, and Pears the winners were Messrs. Howard, Ross, Randall, and Surman respectively. Cherries, Figs, and Plums were also shown.

Vegetables were staged in the open owing to the very large number of other exhibits staged in the tents. The quality of the vegetables shown was splendid. Potatos were remarkable for their clear skin, shape, and good table quality. In both the classes for collection of vegetables Mr. Lye, of Sydmonton Court, was a good 1st.

BASINGSTOKE HORTICULTURAL.

August 6.—The 30th annual summer exhibition of this Society was held in Golding's Park, the seat of Mr. W. C. Lefroy, and was in every way a success.

Plants.—Displays of plants were more numerous than usual. In the class for nine specimen plants Mr. J. Wasley (gr. to J. B. Taylor, Esq., Sherfield Manor, Basingstoke) was 1st, staging, amongst other things, a specimen of Crinum Mooreni, with 24 flower spikes, and a freely-flowered example, 4 feet high, of Thunbergia; 2nd, Mr. Neal (gr. to John Mares, Esq., Manor House, Basingstoke). Exotic Ferns of good quality were freely contributed. Mr. J. Keen (gr. to H. Welch-Thornton, Esq., Beaurepaire Park) won the 1st prize. He showed a remarkably fine plant of Adiantum Farleyense. Mr. Keen was successful for a specimen foliage plant with Cycas revoluta. Mr. Wasley had the best flowering plant in Clerodendron Balfourii. The best group of miscellaneous plants arranged for effect was shown by Mr. Best (gr.

to F. LEYLAND, Esq., The Vyne, Basingstoke). Soft-wooded plants were numerous and good.

Cut flowers made an interesting feature. Mr. Neville (gr. to F. W. FLIGHT, Esq., Cornstiles, Twyford, Winchester) secured the premier awards for 24 and 12 blooms, and for 12 Tea Roses. Carnations were shown well. Mr. Childs (gr to the Hon. Mrs. F. BARING BROWN, Candover) won in the class for 36 blooms in 12 varieties. Mr. WASLEY had the best stove and greenhouse flowers in 12 varieties and the best hardy flowers.

Fruit of good quality was seen. Mr. WASLEY took the 1st prize for a collection of six varieties; also for two bunches of Muscat Grapes, and for two bunches of any black Grapes. Peaches, Nectarines, and Plums in all classes were shown well. Mr. BEST won the 2nd prize in several classes, and he secured the 1st place for any white Grape other than Muscat of Alexandria with Foster's Seedling, in good condition.

Vegetables at Basingstoke are always numerous and good. Mr. BEST won the premier award in Messrs. Sutton's, Toogood's, and Carter's classes respectively with first-class produce.

BISHOP'S WALTHAM HORTICULTURAL.

JULY 31.—The thirty-second annual exhibition of this society, held on this date, was in every way a success. This association was started as a cottage-garden society, and it has done much to encourage horticulture in the neighbourhood. From the cottage element it has progressed, and it is now quite a flourishing society, holding annually an excellent show. Mr. E. Molyneux has been the hon. secretary for the past 20 years.

In the class for six specimen plants Mr. G. Ellwood (gr. to W. H. MYERS, Esq., Swanmore Park, Bishop's Waltham) was an easy winner; 2nd, Mr. G. Simmons (gr. to E. A. PONTIFEX, Esq., Hill Crest, Bishop's Waltham).

Tuberous-rooting Begonias were well shown by Mr. Barnes (gr. to Mrs. AUSTIN, The Thickets, Bishop's Waltham), who won the first place with high-class blooms; 2nd, Mrs. HUMPAGE, Dell Cottage, Swanmore. The best Table plants were contributed by Mr. ELLWOOD.

Cut flowers were numerous and good. For twelve varieties distinct Mr. ELLWOOD staged indoor varieties of a choice character, and won easily. Mr. G. Sherwood (gr. to T. H. GILLSON, Esq., Swanmore Cottage) secured the 2nd place.

Sweet Peas were a strong class. For a collection of these flowers Mr. C. H. Holloway (gr. to Lord ABERDARE, Longwood House, Winchester) was 1st, Mr. Cooper (gr. to Miss GLADSTONE, Harrington Hill, Swanmore) being 2nd.

For the prizes offered by Mr. H. Eckford, Wem, for 12 varieties there was a keen competition. Mr. H. WRIGHT ANDERSON, The Firs, The Chase, Bishop's Waltham, was successful, winning with high-class blooms that were well arranged.

Mr. BARNES won in the class for six bunches, the prize being given by Messrs J. Carter & Co., and Mr. HOLLOWAY secured Mr. Breadmore's prize also for six varieties.

The best six bunches of Roses were shown by Mr. ELLWOOD, but he was closely followed by Mr. H. Childs (gr to Mrs. MACRAE, Mearstoke House, Bishop's Waltham).

For a similar number of Rambling Roses the prizes were again awarded in the same order. Carnations made an interesting display. Mr. COOPER won in the class for six bunches, Mr. ELLWOOD taking 2nd place.

The last-named exhibitor put up an imposing exhibit in the class for 18 varieties grown out of doors which won for him the premier award. Mr. BARNES occupied a similar position for 12 kinds, Mr. CHILDS following.

Table decorations are always a great feature at this exhibition, and on this occasion no fewer than 12 tables were seen. In the open class Mr. CHILDS was awarded the premier position with an arrangement of Carnations, Gypsophila, Ferns, &c., all lightly disposed; 2nd, Miss L. PAYNE, Frogmore, Bishop's Waltham.

In a class for floral decorations devoted to ladies only there was sharp competition. Miss G. MEDLICOTT, Swanmore Vicarage, won with Shirley Poppies pleasingly blended. The best arranged vase contained Dorothy Perkins Rose in masses, with Gypsophila nicely intermixed.

Fruit, although not numerous, was good in quality. In a class for six dishes of fruits Mr. ELLWOOD won, showing Madresfield Court and Muscat of Alexandria Grapes, Peaches, Nectarines, Melons, and Cherries, and the same grower won in the smaller class for four dishes, Grapes being excluded.

In the class for four dishes of outdoor fruits Mr. BARNES took the 1st prize with excellent produce. Especially fine in this exhibit was a dish of Red Astrachan Apples.

The best two bunches of black Grapes were shown by Mr. HOLLOWAY, he having the variety Black Hamburgh. Exhibits of small fruits were numerous and good.

Vegetables were abundant and of high quality. Messrs. Toogood & Sons, Southampton, offered prizes for eight dishes, that brought brisk competition. Mr. BARNES won with a high-class exhibit. Mr. Sherwood (gr. to T. H. GILLSON, Esq., Swanmore) followed closely.

Mr. ELLWOOD won Messrs. Sutton's and Messrs. J. Carter and Co.'s first prizes for six varieties of vegetables.

Mr. SHERWOOD staged the premier collection of Potatos in six varieties.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.—The monthly committee meeting of this society was held at the Royal Horticultural Hall, Vincent Square, Westminster, on the 13th inst., Mr. THOS. WINTER in the chair. Four new members were elected and one nominated. The death certificate of the late Mr. W. C. MARCHANT, of Haywards Heath, was produced, and the sum standing to his credit in the books of the society was granted to his nominee. It was decided to hold the annual dinner in the second week in October; the date and other particulars will be duly announced.

ENQUIRIES AND REPLIES.

APPLES BURIED FOR KEEPING.—In reply to "Taylor," Somerset, *re* burying or clamping Apples similar to Potatos, I have found they keep well until February and March. They will not keep long when taken out of the ground, especially if they are not very carefully handled. They taste a little earthy, but this flavour is lost in cooking, and if they are stored in tins or in boxes, I imagine they would not gain this flavour, as I had only straw between mine, which were buried more in the nature of experiment. Northern Greening was the variety I experimented with. *G. Fulford, Merstham.*

ANSWERS TO CORRESPONDENTS.

AMPELOPSIS VEITCHII, &c.: *J. C.* Cuttings inserted in sand under a hand-light in September in the open border will be ready for planting out the following spring. Ivy cuttings can be propagated in the same manner, or thickly in pots in a close frame, the present being a suitable season for the work. The best plan of raising Grape vines is from "Eyes" or single buds. They should be plunged in a bottom heat of 70° to 80° at the end of January and be kept close and moist, when they will readily form roots. They can also be raised from cuttings of wood in the rest state, but bottom heat is almost essential to promote the formation of roots.

APPLES CRACKING: *A. S.* The cracking is caused by a fungus, Fusicladium dendriticum. See *Gardeners' Chronicle*, July 14, p. 22

BIRCH: *A. B.* The leaves are swarming with aphides. Try spraying the tree with quassia water or even soapy water.

BOOK: *Miss A. R. A. Johnson's Gardeners' Dictionary* will be found useful for your purpose. It can be obtained from our publishing department, price 9s. 6d., post free.

CELERY AND LEEKS: *Constant Reader.* The system is frequently adopted to keep the stems clean and to further expel the light to prevent the formation of the green chlorophyll. We have not heard it recommended in the case of Leeks. You should earth the plants at intervals, beginning now if they are large enough. If the land has wireworm it should receive a dressing of gas lime in the autumn and be allowed to lie fallow for some weeks after. Sow the plants you mention now, and for further information see the *Calendar of Garden Operations*, to be obtained from our publishing department, price 7½d. post free

FUCHSIAS: *E. H.* Try starvation, apply less water, and use smaller pots. Other questions next week

GLOBE ARTICHOKES: *Correspondent.* See note on the subject in our Calendar—the Kitchen Garden, p. 129.

GRAPES: *J. T.* The Grapes are both shanked, and the Muscats are attacked by fungus. Without knowing all the conditions we cannot say for certain what is the cause of the trouble. It may be too much or too little water. Look to the border, and next season spray the Vines with weak Bordeaux mixture.

GUMMING: *R. J.* There is nothing to add to the account of gumming, published in a recent issue.

LILY: *F. S.* What you send is a distorted form of L. auratum, more curious than beautiful. The perianth-segments are all greenish, and the stamens are replaced by carpels which form a ring around the true carpels in the centre, a very interesting case but one which we fear you will not appreciate.

MELONS: *Annoyed.* Your plants are affected with Melon-spot caused by a fungus Cercospora melonis. Remove all the affected plants at once and burn them. Spray the healthy plants with weak Bordeaux mixture, trying it first in order to ascertain what strength to apply it, for if you use it too strong it will injure the foliage. —*W. H. D.* We do not think the risk would be great, but as it is much better to be on the safe side we should certainly recommend you not to eat the fruit.

NAMES OF PLANTS: *T. O.* No. 3 (from last week), Napæa dioica.—*A. P. N.* Probably Allium multiflorum. You should have sent foliage.—*R. S.* Centaurea suaveolens, one of the many varieties.—*W. Y. S.* 1, Leycesteria formosa; 2, Verbascum sp.; 3, Aconitum Napellus, poison; 4, Lythrum Salicaria; 5, Aconitum Lycoctonum, poison.—*F. C. L* Indigofera decora.—*R. S.* Alonsoa incisa. It does very well as a summer bedding plant.—*A. M.* 1, Phragmites communis; 2, Eupatorium cannabinum; 3, Agrimonia Eupatorium; 4, Inula dysenterica; 5, Hypericum perforatum; 6, Epilobium hirsutum. —*J. M.* 1, Angelica silvestris; 2, Sison Amomum; 3, Dipsacus pilosus; 4, Calamintha clinopodium; 5, Galeopsis Tetrahit.—*F. E. A.* 1, Spergularia rubra; 2, Pernettya mucronata; 3, Centaurea Jacea; 4, Lycium sinense; 5, Solidago virga aurea; 6, Syringa Josikæa.—*Miss L.* Hedychium Gardnerianum, one of the Ginger family.—*Interested.* Rhus Cotinus. The true flowers are not formed, or only very sparsely —while the flower-stalks are very numerous and slender—forming an intricate mass, whence the plant is called the Wig Plant.—*F. S.* Hibiscus syriacus, frequently but erroneously called Althæa frutex.—*Batum, Russia.* 1, 2, 5, we do not know these plants, and they are not included in the *Index Kewensis*; 3, New Zealand; 4, Chile.

NECTARINES: *W. & T. S.* The stones are split and decay starts from the centre and extends outwards, which indicates a too liberal supply of water. There is no fungus disease present.

PÆONY FAILING: *G. W.* Without seeing a portion of the plant we cannot be certain, but we suspect the Pæony disease, Sclerotinia pæoniæ is the cause of the trouble. See *Gard. Chron.*, August 13, 1898, with figure.

TOMATO: *A. G. H.* A dessert variety of fair size. We can't tell the name from the berries only.

TO MAKE LAVENDER WATER: *Inquirer.* To one pint of highly rectified spirit of wine add essential oil of lavender 1 ounce, essence of ambergris 2 drachms; put all into a quart bottle and shake it extremely well. You would not be able to make it from the flowers satisfactorily without a course of instruction and expensive apparatus.

WILLOW: *A. B.* The galls are produced by a fly, a species of Cecidomyia. You can do nothing but burn as many of the affected leaves as you can.

BALMAE, KIRKCUDBRIGHT.

THERE are few gardens which do not yield some pleasure, although it may be that this is mingled with regret at so many unsatisfactory features. Old-world gardens, however, possess a special charm, wherever they retain their ancient features, mingled though these may be with the modern in the shape of improved varieties of old plants or others unknown when the garden was first made. This charm is all the greater when, as in the subject of this notice, the garden is the pleasure of an owner of taste, and with a love for its adornment.

Balmae, Kirkcudbright, the residence of the Countess of Selkirk, is one of these old places which one still meets with here and there, which have as their accessories quaint old gardens embodying the features of bygone days, and bearing about them marks of their antiquity. It seems to have been designed and laid out with a view to enclose within its walls a variety of features, so that, sheltered from the storms which at times sweep swiftly and wildly up the Solway, the dwellers in the mansion near by might enjoy the shady and the sunny walks, the little lawns, the miniature lake, which lies in a corner of the garden, and the view of the flowers, the fruit, and the vegetables, which then, as now, occupied its area.

Balmae is also out of the beaten track of garden pilgrims, and those seldom find their way to this sequestered spot, which lies some five miles from Kirkcudbright, and in a beautiful position, close to the sea-coast of that portion of the Solway between the Dee and the Urr.

The mansion itself is of considerable age, and possesses a singular architectural feature in the shape of a massive portico and pillars, which seem to have been designed for a much larger house, and which set one wondering whether they were part of the original plan or were added at a later period. Although not of a size proportionate to the portico, the mansion is of good size and of the good old Scottish type, where no space is wasted by a redundance of architectural features, and eminently suited for an exposed position in a rainy district such as this. The small formal flower garden lies to the back, or garden front, and consists mainly of bedding plants arranged on the lawn. This is surrounded with trees of considerable age and size, and there is consequently some deficiency of sun for the plants, which, however, are looking well despite the difficulties of their position. Some good Asters were among them. The garden front of the house is largely covered with creeping plants.

A short distance from the mansion we come to the garden proper, which is of large extent, and is one which has evidently retained many of the old features which have characterised it for years. It is difficult to describe such a garden, but an attempt must be made. The walls are about eleven feet high, and are mainly covered with fruit-trees, from which good crops are generally obtained. This year fruit is much more plentiful than is general in this part of Scotland, and on the walls a plentiful supply of Apples, Pears, Peaches, Nectarines, Plums, and other fruits has been secured. A notable feature of the fruit walls is one facing almost north, and covered with Morello Cherries, from which splendid crops are derived. Hardy fruits are those most cultivated here, and the walls are thus utilised to the best advantage. Some of the other fruit trees are old, but good crops are the rule.

As with fruits, so with flowers. Outdoor flowers are the special favourites of Lady Selkirk, who has also a preference for the taller and bolder hardy flowers. A number of these have been at Balmae for some time, and some of the older plants are hardly ever met with now in gardens. One cannot detail the flowers at length, but reference may be made to some. There is a fine plant of Eremurus robustus, ten feet high this year, a handsome Romneya Coulteri, a number of good Delphiniums, many Phloxes, Sida Napæa, the old Salvia glutinosa, Phlomises, a great mass of Geranium striatum, covering the side of a bank near the conservatory, and very beautiful indeed; Clematis recta and C. integrifolia, great clumps of Eryngiums, including the fine E. alpinum; Statice latifolia, an extensive collection of Asters, including such as Edna Marcia, Perry's Pink, Perry's Favourite, and a number of other modern varieties, as well as the best of the older. Then there are the species of Asclepias, such Coreopsis as Eldorado and others, Rudbeckias, Inulas, Cimicifugas, Verbascums, a great number of plants of Veratrum viride, giving fine spikes; Monardas, Campanulas, and, in short, a good representation of the best of the border plants; while spring flowers are also in great numbers, including Irises, Narcissi, Snowdrops, &c.

The Shrubs in the garden are both numerous and interesting. The hardy Fuchsias naturally attract attention, as there are enormous plants, such as one of F. gracilis, some eleven feet high in a border and by the wall; and another not so tall, but of huge circumference, and in the open. There are Deutzias, large Berberises, Roses, both old and new, bush and climbing; large old Tree Pæonies, and enormous bushes of Rhododendrons.

Among the trees in the garden, I noted a large Araucaria imbricata, which looks as if it had been among the first of these trees to be grown in this country, and, with a couple of great Yews, is growing by the side of the little lake which occupies a corner of the garden.

A most unusual feature of such a garden is a long walk covered by old Sycamores, planted on either side, and kept pollarded. It goes by the name of the pollard walk, and is a pleasant path in the height of summer, and looks pleasing even in winter. Here we come upon a little grassy glade-like corner with an Arundo and groups of large Rhododendrons, and other shrubs; and anon we wander into another of somewhat similar character, the whole being more attractive because of the undulating character of the ground, which is of a varied contour.

It will not be possible to omit the Sweet Peas, of which there are numbers in lines and in pyramids. These include the best of the newer varieties, and among them a group of a fine-coloured sport from Countess Spencer, which seems to have been fixed by Mr. M'Guffog, the gardener at Balmae. Carnations and early Chrysanthemums are also largely cultivated, with other annuals besides the Sweet Peas.

The glass department is not extensive, but is commensurate with the requirements of the household. The conservatory is well supplied with flowers of the various seasons, and some excellent Begonias, Zonal, and other Pelargoniums, Celosias, and seasonable flowers of various kinds were in bloom. The vineries are well cropped and other indoor fruits and plants well grown.

The vegetables form an important part of the work of Mr. W. M'Guffog, and he has for a long time made a special feature of Onions, which have been looking well this year, as in former ones, when they have taken a high place in competition. Other vegetables are as well done in proportion, and the whole garden presents a number of interesting features. One not seldom seen really lies outside the garden proper, as it is on the outside of the wall occupied by the Cherries. It is ornamented with thousands of plants of the charming Erinus alpinus, which grow admirably in the joints and crevices of the wall. *S. Arnott.*

NURSERY NOTES.

THE ROYAL NURSERIES, WALTHAM CROSS.

THE long-established firm of Wm. Paul & Son is known wherever the Rose is grown for the beauty of its flowers; and probably it is not unknown even in Bulgaria, the home of the Attar of Rose industry.

I was fortunate, on the occasion of a recent visit to Waltham Cross, to find Mr. Arthur W. Paul at home, and having introduced myself, and stated the object of my visit, he courteously conducted me through the home nursery, and furnished enough particulars about the various "new creations" and varieties of the Rose as would have filled, could they have been jotted down as spoken, several pages of this journal; and not alone about Roses, for this home nursery is but a kind of sample ground, where some of the best examples of everything that is cultivated at the branch nurseries may be found. These latter are situated at Loughton and at Broxbourne

The soil of the home nursery is an ideal one, it being a cool, tenacious loam; as Mr. Paul tells his readers in a preface to his catalogue of hardy ornamental trees and shrubs: "The stock is consequently never forced into excessive growth, nor injuriously affected by the most varying seasons. The earth adheres to the roots during removal, thereby almost ensuring success after careful transplantation."

And such I found it to be—friable, even lumpy on the surface, apparently dry, but on scraping a hole with the toe of the boot it was discovered to be agreeably moist below; and yet they had had little or no rain and a brilliant sun overhead for two months. The stocky, moderately strong growth on everything around showed how well a dry season was borne by the trees and shrubs and the Roses. Few nurseries possess a grassy avenue, 20 feet in width, bordered with Conifers and other ornamental trees and shrubs running through from one end to another a quarter of a mile in length. Yet this is the case here, and exceedingly thrifty every plant looked, nothing overgrown as to size, but just as the landscape gardener likes to have his plants.

Roses still flowering in some abundance, with

FIG. 50.—ROSE DR. WM. GORDON: A NEW HP. WITH SATINY PINK COLOURED FLOWERS. (HORT. W. PAUL AND SON).

here and there a variety with nothing visible but the withered glories of a few weeks ago, were the first to which Mr. Paul directed my attention. By the end of September the second flowering of Hybrid Perpetuals, Teas, and Hybrid Teas will be at its best, but let us enjoy the summer feast of Roses while we may. The Wichuraiana Rose, as parent, has made its tween Perle des Jardins and R. Wichuraiana, has large, graceful flowers that are at first lemon-yellow and then white. Its almost innumerable flowers have been succeeded by a heavy crop of seed-pods. Another great pyramid was Deschamps, a Hybrid Noisette, which in two years from a mite in a pot when planted out had grown into a well-furnished specimen 9 feet China, of which many were observed, another Rose like the last, good for beds, is Pissardi, a sub-species of Rosa moschata, flowers semi-double; Eduard Meyer is also semi-double of a light rose tint. On plants of Victor Hugo, a fine crimson-scarlet H.P., many blooms were noted. The fine large blooms of H.P. Her Majesty were noted on dwarf plants one year

FIG. 57.—ROSE DAVID R. WILLIAMSON: A CRIMSON AND RICHLY FRAGRANT H.P. VARIETY (HORT. W. PAUL AND SON).

mark on many of the new climbing varieties Ramblers, as it is now the fashion to name them. The first of Hybrids from Rosa Wichuraiana noted was the very floriferous Dorothy Perkins, Madame Gabrielle Luizette being in this case the other parent. The Farquhar, the result of a cross between R. Wichuraiana and Crimson Rambler. A 10 feet high pyramidal plant of Jersey Beauty, an American cross be- high. Of other climbers may be mentioned climbing Cecile Brunner, an Australian variety of a light pink tint, pretty, more especially when in the bud stage, and flowering with the utmost freedom. Madame Hector Leuilliot (new), a climbing Tea, and very distinct, Madame Moreau, a strong grower, with flowers resembling those of Sunrise, a coppery tint of apricot; Gruss an Teplitz, a brilliant scarlet Hybrid old. The varieties Gustave Piganeau, La France, and General Baron Berge, flowers not unlike those of Geant des Batailles, and a good grower, with a much-branched habit of growth; Jubilee, a grand crimson-coloured Rose, like Prince Camille de Rohan, but flowering with greater freedom. It comes from America. Madame Frau Karl Druschki, the Schnee Konigin of German Rosarians, has been,

and still was, excellent out of doors, the hot, dry season just suiting its needs. Soleil d'Or, a cross raised by Mr. Paul from Antoine Ducher, a red flowering H.P., and Persian Yellow, the colours of the cross being intermediate between those of the parents was observed.

There are several span-roofed houses of larger dimensions containing Roses in pots of Tea and Hybrid Tea varieties, strong plants for winter forcing, which have made fine growth, the process being aided by the removal of all blooms as soon as these appear. Another house was filled with seedlings, whose record as to parentage is carefully noted. Two large houses contained climbing Roses, Ramblers, Teas, and others; one other was filled with such climbing varieties as Lady Gay, apparently the best of this section, so far, Dorothy Perkins, and others. Many plants were observed in pots of the fine Earl of Warwick and Dean Hole. A span-roofed house, 120 feet long, and perhaps 30 feet wide, contained climbing Roses and dwarfs, the latter for forcing in the winter.

Many lights were filled with Roses resting, and among them Etoile de France, a fine large crimson flower—an up-to-date collection, as Mr. Paul remarked on showing them.

Out of doors there was the same abundance of Roses, including numerous climbing varieties ripening their growth, excellent for spring planting. Mr. Paul strongly advising the planting of strong plants out of pots just as these begin to grow in preference to autumn planting. The variety Warrior is greatly liked as a spring forcer; it is a cross from Papa Gontier, a deep crimson flower, and very fine as a bedding Rose. Another that is good for bedding out is the floribunda (Noisette), blush coloured, free, and of moderate growth; it also makes a capital hedge. Hybrid Tea Ireno was noted in the open quarters. The flowers of the palest blush tint come in great heads. H.T. Countess Cairns is of a beautiful shade of pink, a full flower, and the plant very free, as is likewise Mrs. Dudley Cross, with cream coloured flowers, the outer petals having a pinkish tinge. It is not yet in commerce. These four last-named Roses were raised in the nursery, as were the recently-raised Dr. Wm. Gordon, H.P., a pink coloured satiny flower, with very fine petal (see fig. 56), and David R. Williamson, H.P., with deep crimson and richly fragrant flowers (see fig. 57); Pharisaer, a tender blush coloured flower, is a beautiful thing, exceedingly nice in the half-opened stage.

The general stock of fruit trees of all kinds, trained and otherwise, can scarcely be excelled for form, strength, and cleanliness.

Rarities in ornamental subjects are many, and the following may be cited. Cytisus Shipkaensis, a white species, flowering after midsummer; Rhamnus californica, an evergreen, with red Holly-like berries; Gingko biloba pendula; Podocytisus caramanicus (Laburnum), an erect growing, yellow-flowered shrub, as seen about 4 feet in height, the flowers disposed in erect spikes; a weeping form of Betula nigra, quite distinct, Colutea bullata, &c. *F. M.*

REMARKS ON THE CONDITION OF THE FRUIT CROPS.

(See Tables and Summaries, ante, pp. 64-70.)
(Concluded from page 126.)

WALES.

CARNARVONSHIRE.—Cold north-east and easterly winds, sometimes quite a gale, blowing for nearly six weeks, during which time most of the trees were in flower, account for the scarcity of fruit in our district. The soil in our gardens is of a heavy, retentive nature, overlying limestone. *H. Weaver, Faynol Park Gardens, Bangor.*

——A prevailing east wind in March, April, and May, with severe hail storms which cut the blooms clean off the trees, were the causes of the shortage in our fruit crops. The soil is light in texture, resting on hard rock. *W. Speed, Penrhyn Castle Gardens, Bangor.*

DENBIGHSHIRE.—The cause of the failure in our fruit crops was the cold and frosty spring, with showers in the afternoons and frost in the mornings of most days. Our soil is of a light nature, with a subsoil of sand and gravel. *Walter Weir, Rhosnessney, Wrexham.*

FLINTSHIRE.—Cold winds and frost in May were the causes of a poor fruit season. *John Forsyth, Hawarden Castle Gardens, Chester.*

GLAMORGANSHIRE.—All kinds of fruit trees gave promise this spring of record crops, but owing to the cold winds and little sunshine all through the month of May, Plums and Pears are a total failure. Strawberries were a record crop, but quite half the fruits were spoilt by continued rain and fog during the ripening period. Peaches and Nectarines are very good, and the trees are healthy and free from blister. Apples also are very good, but blight has been very prevalent on the young growths, as it also has been on Plum shoots. All small fruits are plentiful and good, especially Raspberries. Our soil is a light loam, resting on a sub-soil of gravel. *R. Milner, The Gardens, Margam Park, Port Talbot.*

MERIONETHSHIRE.—During the time Pears, Plums, Cherries, Gooseberries, &c., were in full bloom, we registered 8° and 12° frost for two nights in succession, and this ruined the crop. The spring was very wet and cold, with easterly winds, and this was followed by very dry weather. Our soil is a rather light loam, and one that dries quickly. The sub-soil is gravel. *J. S. Higgins, Rhûg Gardens, Corwen.*

MONTGOMERYSHIRE.—No frost of any severity was registered in the early spring, and the trees looked promising and full of fruit buds. An abundant year for fruit was anticipated, but the long and continued east winds blighted the trees so that the fruit all fell off. The soil is stiff loam, with a clayey sub-soil. *J. Lambert, Powis Castle Gardens, Welshpool.*

PEMBROKESHIRE.—The cold and wet of May much injured the fruit crop in this district. In many cases the Apple crop is a failure. All the trees which blossomed in April (which, with us was very dry), such as Pears, Apples, Plums, and Cherries on walls are a good crop. Insects and mildew have been very troublesome this season, and I hold the opinion that they have become much more prevalent of late years. *Geo. Griffin, Slebech Park Gardens, Haverfordwest.*

9.—IRELAND, N.

ANTRIM.—The blossom on all kinds of fruit trees in this district was very abundant, and promised record crops, but the late frost and cold north-east winds account for almost a complete failure of Pears and Plums. Strawberries have been a splendid crop, and all small fruits have been good. Some varieties of Apples are carrying good crops, others have none. May 16 and 17 saw a gale from the north-east, which blackened even some of the young Beech leaves. Our soil is very wet and heavy, on a sub-soil of clay. *J. MacLean, The Gardens, Shanes Castle.*

CAVAN.—The cold east winds in May and the heavy rain spoiled much of the fruit blossom. Royal Sovereign Strawberries have borne an enormous crop of very fine fruits. The soil is a rich loam about 3 feet deep, resting on limestone rock. *Wm. Berry, Farnham.*

DUBLIN.—The causes of a partial failure in the crops of Pears, Plums, and small bush fruits are the sharp frosts, cold winds, and low temperature in April and May. The soil is a good stiff loam, on a hard calcareous bottom about 2 feet below the surface. *A. Campbell, St. Anne's Gardens, Clontarf.*

GALWAY.—I never saw greater promise for fruit than when the trees were in blossom, but Pears and Plums suffered much from severe frosts in April—on the 19th of that month we registered 11° frost. In May the Apple crop also suffered from low temperatures and showers of hail, which also affected the Strawberries and Raspberries. *And. Porter, The Gardens, Woodlawn.*

——Late spring frosts checked growth and brought a plague of aphis, which seriously affected the crops of Plums, Damsons, and small fruits. The soil is a light loam, resting on adhesive yellow clay. *Thomas Dunne, Lough Cutra Castle, Gort.*

MAYO.—The weather in spring-time was unfavourable to all crops. Little growth was made during the month of May owing to frost each night. Potatos are a month late. The soil is loamy; the sub-soil is a hard, yellow kind of clay. *Patk. Connolly, Cranmore, Ballinrobe.*

MEATH.—The fruit crops were almost ruined by the cold weather in spring-time. Such frost was seen in May, that it was like winter. The soil in most parts is a heavy loam. *Michael M'Keown, Julianstown, Drogheda.*

TYRONE.—The persistent frosts and cold weather of March and the first three weeks of April destroyed the Pear and the Plum crops. It had, however, a contrary effect upon Apples, for it retarded the bloom of these trees, and, thanks to a fine, mild May, we have a good crop of Apples. The soil here is rather shallow and cold, of a heavy texture, approaching that of clay. It is deficient in lime, but, when well drained and cultivated, good crops result. *Fred. W. Walker, The Gardens, Sion House, Sion Mill.*

WEST MEATH.—Late frosts, with harsh winds and heavy showers, destroyed the blossoms of our fruit trees and caused many of the young fruits to fall. Both soil and sub-soil differ in parts of these gardens, but for the most we have a medium heavy loam, overlying a cold, yellow clay, the former being very shallow in places. *George Bogie, Pakenham Hall Gardens, Castlepollard.*

WICKLOW.—All fruit trees looked promising in the early spring, and bloomed abundantly, but the fruits were destroyed later by cold east winds during April and May. The soil is gravelly, on a sub-soil of clear gravel. *W. Owen, Powerscourt Gardens, Enniskerry.*

——Apples, Pears, and Plums are an average crop. Black Currants were so infested with the "bud mite" that the crop is a failure. Red Currants and Gooseberries have been an abundant crop, but, unfortunately, owing to the ravages of wood-pigeons (which in our locality are a perfect plague) we shall not harvest many. Raspberries and Strawberries are an abundant crop, and the fruits are very fine in quality. *D. Brough, Coollattin, Shillelagh.*

10.—IRELAND, S.

CARLOW.—The promise of a record fruit year was frustrated by a severe frost on May 10. Daily showers caused much of the Strawberry crop to rot. The soil is a sandy loam of a light texture, resting on a gravelly marl sub-soil. *F. Browne, The Gardens, Borris House, Borris.*

CLARE.—Very unseasonable weather prevailed throughout May, especially about the middle of the month, when we had violent and piercing cold N.W. winds by day and very cold nights. Easterly winds also did much damage, tree foliage being much blackened in consequence. Hosts of green and black fly made their appearance on Plum and Cherry trees. We also had very bad weather during the greater part of April, in which there were cold and violent N.W. winds by day, with frequent light frosts at night. Much damage was caused to early Potatos in this locality from this cause. Sub soil, retentive clay and limestone rock; this applies to the district in general. *Alfred Barker, Carrigoran, Newmarket-on-Fergus.*

Cork.—Seven degrees of frost on April 16 and nine degrees on April 19 destroyed the Damson and the Plum crops on Pyramid and Standard trees. Our soil is a good rich loam on a sub-stratum of limestone. *C. Price, The Gardens, Mitchelstown Castle.*

Kildare.—Crops of Apples, Pears, and all stone fruits are very unsatisfactory. The damage was caused by the severe frosts of April 19, when 13° were registered, and May 11 (12°). The prevalence of east winds during the whole of April and May also adversely affected the crops, while insect pests have not been so troublesome since 1887. Our soil is heavy, and largely impregnated with lime. The sub-soil is a bluish marly clay, which holds water equal to cement and will turn the point of a pickaxe: beds cut in grass fill and overflow with water in winter. *Fredk. Bedford, Straffan House.*

Kilkenny.—We should have had record crops, but for the north winds and late frosts. Fruit growing in this locality is making rapid progress, owing to the encouragement given by the Department of Agriculture. The soil in this district varies from a good loam, with a gravelly sub-soil, to soil of a very sandy nature. *F. France, Bessborough Park Gardens, Piltown, Ireland.*

Roscommon.—Sharp frosts, accompanied by hail and cold winds in April and May, adversely affected the fruit crops. The soil in our gardens rests on a clayey sub-soil, is very retentive of moisture, and generally bad. *Terence Rogers, Frenchpark House Gardens, Frenchpark, Co. Roscommon.*

Tipperary.—The severe weather in April and May spoiled what promised to be a good crop of Pears and Plums. The soil is of a loamy marl; sub-soil stiff, marly loam. *John Doolan, The Gardens, Minella, Clonmel.*

Fig. 58.—Lathyrus violaceus: flowers violet-blue with darker veining.

CHANNEL ISLANDS.

Jersey.—Cold and wet in the spring-time adversely affected the early fruit-blossoms. Apples suffered very badly. Some varieties of Pears, such as Doyenné du Comice and Chaumontel, are carrying good crops. We grow no Plums. Our soil is of good quality, the sub-soil being 18 inches below the surface. *Robert Reed, Spring Grove, St. Lawrence, Jersey.*

Isle of Man.—Late frosts in spring-time and prevailing east winds account for the shortage in our fruit crops. Fruit and all other crops are a fortnight later than in ordinary seasons. Our soil is shelly on a sub-soil of blue and white clay. *Jas. Inglis, The Nurseries, Brunswick Road, Douglas, Isle of Man.*

NEW OR NOTEWORTHY PLANTS.

LATHYRUS VIOLACEUS.

Early in the present season we received flowers of this species from Mr. T. Smith, Newry, whose nursery contains many choice and rare plants. The flowers were produced in a cold house, and Mr. Smith remarked that he did not know whether the species would prove hardy in Newry or not, but from its habit of growing so early in the season he feared it would always require shelter. A note by Mr. Burtt Davy, published in these pages, March 31, 1894, describes the species as coming from the mountains of Los Angeles Co., Southern California.

In the gardens of the University of California, at Berkeley, the plant grows from 6 to 8 feet high and is abundantly covered with light-green foliage (there are about 12 small leaflets to each leaf). The flowers, which are produced in great profusion on racemes bearing 10 to 14 blooms each, are about eight lines long, violet-blue in colour, the banner being veined with darker, nearly parallel veins.

IRIS (XIPHION) TAITII.*

In 1904 my friend the Baron de Soutellinho, of Oporto, sent me bulbs of an Iris which he thought might be those of I. filifolia. They flowered with me at the end of June, 1905, and showed characters which appeared to me sufficient to justify a new specific name. I waited in the hope of confirming my observations by means of the flowers of this year; but, alas! I have had none. So I must trust to what I saw last year.

The plant is obviously not I. filifolia, or any variety of that species: the complete absence of any tube alone shows this, to say nothing of colour and other features.

It is nearly allied to I. Xiphion, but differs (1) in the small bulbs with light-brown finely-ribbed coats, (2) in the form of the outer petal, which is less panduriform and has a narrower "signal," (3) in the filiform leaves, and (4) in the time of flowering, which is later than that of I. Xiphion. Nor have I ever seen any variety of I. Xiphion with the same colouration. By its leaves and late flowering it comes near to I. serotina, but differs in the bulb characters, in the form and in the colour of the flowers.

I think I may venture to consider it a new species, and I propose to call it by the name of the finder, using, however, the more familiar name by which the Portuguese Baron used to be known to his many friends, and so naming it Iris (Xiphion) Taitii. *M. Foster, Shelford, Aug. 8, 1906.*

* Iris Taitii, *sp. n.* Flowering bulbs small (1·5 cm. × 3 cm.) with thin light brown, finely but conspicuously ribbed coats. Leaves, awl-shaped, 40-50 cm. long, four or five to the scape, which they clasp to some extent. Scape about 60 cm. long, the upper 10 cm. being quite naked, bearing (?) a single flower. Spathe valves conspicuous, the outer 10 cm. × 3 cm. much longer than the ovary. Outer sepal (fall) somewhat panduriform, the blade orbicular on a light lavender colour, with thin inconspicuous veins of deeper purple. Apex distinctly emarginate. Signal, a long narrow oval of a bright orange colour, raised in the median line into a distinct ridge. Claw of the same colour as the blade. Whole petal 5·4 cm. × 2 cm. Petal (standard) obovate-lanceolate of a blue-purple colour, much deeper than that of the fall. Apex distinctly emarginate; whole petal 6 cm. × 1·4 cm. Style, with the large quadrate-crenate crests, 5 cm. × 1 cm., of a pale lavender colour. Tube none. Ovary, 3 cm. long by 5 cm. wide, trigonal with concave sides. Peduncle, 4 cm. long. Capsule and seeds not seen. The whole flower is turbinate at first, but expands quite flatly later. It seems wholly without odour. It opened its first flower with me on June 29. It was found a little south of the town of Abrantes in Portugal *M. Foster.*

ORCHID NOTES AND GLEANINGS.

BULBOPHYLLUM LOBBII CLAPTONENSE.

SOME years ago there appeared in Messrs Hugh Low & Co.'s Nurseries, Bush Hill Park, Enfield, a very fine Bulbophyllum which appeared to be so distinct from any other in cultivation that it was provisionally named B. claptonense. More recently it was shown as B. Lowii, the name under which it had been previously exhibited having been overlooked. In colour it resembles a fine variety of B. Dearei, but that species is readily distinguished by the remarkable structure of the labellum, the hinged front of which has the callus merging into the sides of the labellum, which are extended back into the form of the letter U, the extension constituting a very remarkable counterpoise to the weight of the front when set in motion.

In this case the value of a figure of a type specimen is well demonstrated, for reference to the figure of the typical B. Lobbii, *Bot. Mag.* t. 4532, plainly shows Messrs. Low's plant to be a finer form of that species and that the plant so named in gardens generally is very inferior to it in point of beauty and is much nearer in colour to B. siamense (Rchb. f. *Gard. Chron.* 1867, p. 532).

B. Lobbii claptonense differs from the type in its darker, reddish-chocolate markings and in the rose-purple tint of the front of the lip. The habit of the plant is the same as that ordinary B. Lobbii. Scapes erect 4 inches, one flowered, flowers 2½ inches across. Dorsal sepal 2 inches in height, ⅝ inch wide, Indian-yellow in colour with dotted lines of reddish-chocolate, more pronounced on the back than on the inner surface. Lateral sepals lanceolate, falcate, saccate at the base 1½ inches long, ⅜ inch wide, yellow with red-brown lines from base to tip, the outer halves being dotted with red-brown. Lip cordate, hinged, recurved at the apex, whitish, blotched with rose-purple, margin fringed (as seen with a strong lens), callus cushion-like, composed of closely arranged ovoid papillæ, orange at the base, whitish in front, dotted with purple; column whitish with pale-yellow margin and back.

It is a very handsome plant and a form new to gardens.

The B. Lobbii usually found in gardens has the odour of freshly-cut Cucumber. The flower of B. l. claptonense described, seems to have a faint odour like the Cowslip, but this requires verifying.

It flowered lately at Glasnevin and in the gardens of the Hon. Walter Rothschild. *J. O'B.*

A FLOATING ORCHID.

THE August number of the *Orchid Review* has an extract relating to a species of Habenaria (H. repens) found by Dr. Rusby in the delta of the Orinoco. The plant grew in the midst of a floating mass of vegetation, a rhizome about an inch long and one eighth of an inch thick was imbedded among the plants rising obliquely from them, and at the top of this the stem grew erect, in no case much more than 6 inches above the surface. The yellowish white roots well clothed with short and thick root hairs did not dip down into the water, but spread out almost horizontally through the mass of vegetation. The inflorescence was of a light green colour.

THE ROSARY.

THE ROSE GARDEN AT THE MANSE, BRACEBRIDGE, LINCOLN.

(Concluded from page 128.)

MUCH more might be written on other departments of this garden, and especially on that devoted to hardy fruit, but I will merely give a short selection of a few of the best Roses used by Mr. Ellison to bring about such a lovely Rose exhibition as that which I have so faintly endeavoured to describe. The beginner in Rose growing may plant these sorts with all confidence:

HYBRID TEAS.—Florence Pemberton, Antoine Rivoire, Ards Pillar, Augustine Guinoisseau, Captain Christy, Caroline Testout, Climbing Captain Christy, Climbing Caroline Testout, Climbing Kaiserin A. Victoria, Countess of Caledon, Dawn, Gloire Lyonnaise, Grace Darling, Gustave Regis, Irish Glory, Kaiserin Augusta Victoria, Killarney, Lady Battersea, Lady Moyra Beauclerc, Liberty, Madame Chatenay, Madame Jules Grolez, Madame Pernet Ducher, Madame Ravary, Mamie, Marquise Litta, Mildred Grant, Mrs. W. J. Grant, Papa Lambert.

BOURBON ROSES.—Climbing Souvenir de la Malmaison, Reine Olga de Wurtemburg.

TEA-SCENTED ROSES.—Belle Lyonnaise, Hon. E. Giffard, Caroline Kuster, Lady Roberts, Catherine Mermet, Madame Chedane Guinoisseau, Madame de Watteville, Madame Falcot, Madame Hoste, Madame Lambard, Maman Cochet, Marie Van Houtte, Mrs. E. Mawley, Papa Gontier, Prince Theodore Galitzin, Rainbow, Souv. de Catherine Guillot, Souvenir de Pierre Notting, The Bride, White Maman Cochet.

NOISETTES.—Aimée Vibert, Alister Stella Gray, L'Ideal, Longworth Rambler, W. A. Richardson.

HYBRID PERPETUAL.—Ard's Rover, Baroness Rothschild, Bob Davison, Captain Hayward, Charles Gater, Charles Lefebvre, Cleo, Dupuy Jamain, Ella Gordon, Etienne Levet, François Michelon, Frau Karl Druschki, General Jacqueminot, Horace Vernet, La France, Madame Victor Verdier, Margaret Dickson, Marie Baumann, Marquise de Castellane, Merveille de Lyon, Mrs. John Laing, Mrs. Sharman Crawford, Paul Neron, Prince Camille de Rohan, Senateur Vaisse, Thomas Mills, Suzanne Marie de Rodocanachi, Tom Wood, Ulrich Brunner, Victor Hugo, Xavier Olibo.

DWARF POLYANTHA ROSES.—Cecile Brunner, Gloire des Polyanthas, Leonie Lamesch, Madame N. Levavasseur, The Pet.

CLIMBING POLYANTHA ROSES. Dorothy Perkins, Leuchtstern, Queen Alexandra, Wallflower.

CHINA ROSES.—Fellenberg, Laurette Messimy, Queen Mab.

VARIOUS VARIETIES. York and Lancaster, Blairii No. 2, Carmine Pillar, *O. 7.*

The Week's Work.

THE FLOWER GARDEN.

By HUGH A. PETTIGREW, Gardener to the Earl of PLYMOUTH, St. Fagan's Castle, Glamorganshire.

Spring and Early Summer Gardening.—It is not too late to sow such spring-flowering plants as Myosotis, Wallflowers, Polyanthus, and Daisies, though it is preferable to have sown them earlier and to have the seedlings by this time ready for planting into rows in the nursery. If sown now it will be better to utilise warm frames for the purpose as a little extra heat will hasten their growth and afford protection until they are sufficiently robust to plant out in their flowering quarters. If cuttings of Arabis, Aubrietia, and Alyssum have not been already inserted, a stock can be had by inserting small divisions of the old plants into light soil in the open. They must not be allowed to become dry, and water must be given whenever the weather necessitates it. Dwarf Phloxes, such as P. verna and P. procumbens, may be treated in the same manner. Gentiana acaulis, a delightful plant that succeeds well in a rather heavy soil, should now be increased by division. The tufted Pansy can be propagated in numbers by cuttings. The use of annuals and biennials raised from autumn sown seeds is to be commended. For a continuation of a display of flowers in spring-time when bulbous plants and the other spring flowering subjects above enumerated are over, the present is an appropriate time at which to sow for this purpose, and in doing so care should be taken to sow very thinly in the quarters where the plants are intended to bloom. The seedlings should be thinned out early, so that they may become sturdy and robust before the winter commences. The following are a selection well adapted for this kind of work. Clarkia, Godetia, Eschscholtzia, Leptosiphon, Calendula, Nemophila, Virginian Stock, Shirley Poppy, Centaurea, Phacelia, Linaria, and Limnanthes.

THE KITCHEN GARDEN.

By J. GIBSON, Gardener to His Grace the Duke of PORTLAND, Welbeck Abbey, Notts.

Spring Cabbages.—The first sowing of these vegetables will now almost be ready for transplanting. This is an important item in the successful culture of Spring Cabbages, for if the seedlings are placed 3 inches apart on a well-cultivated piece of ground, they will be in a much better condition when ready for planting in their final quarters than if they had been taken straight from the seed bed. Another sowing should be made for succession and to supplement the earlier sown batch.

Lifting Potatos.—In most gardens it is not advisable to leave the main crop of Potatos for too long a period in the ground, for in soils of a fairly rich nature a sudden rainstorm is often the means of starting the tubers into second growth, after which they are never again in the same keeping condition. I do not consider it necessary to wait until the top growth dies down, but prefer lifting when the skins of the tubers stand the digging process without becoming bruised. Store them in a cool place in a cellar and cover them with any material that excludes most of the air and all the light, otherwise they soon become green and unfit for culinary purposes. Select all the seed tubers at the time of lifting and they will be the better for a few days' exposure in the open, for this will toughen their skins and thus ensure their keeping. All early varieties should now be lifted and stored. Make a note of those varieties that succeed best in the particular garden of the grower.

Leeks.—Leeks intended for show purposes should, by this time, have had sufficient soil drawn to their stems to complete their blanching. It is useless to defer earthing, as is sometimes done, until the show is at hand, in the hope of gaining length of stem. The only result obtained will be a partial bleaching of the lower ends of the foliage, thus doing far more injury than good. Endeavour, in bleaching, to secure a well marked division between the white stem and the green part, and not to allow the one colour to run into the other. Prevent the soil falling between the bases of the leaf-blades, as this is not readily got out, but is retained and clearly shows through the white skins.

Blanching Endive.—The early batches of Endive are growing fast, and blanching will require to be carefully done from now onwards. When the plants are strong, as they should be, and the outer leafage well tied up to a point, perfect etiolation results. The use of inverted flower pots is to be recommended when the plants are not robust. Another good system is to cover the heads with dry leaves, covering a part of the border only at one time in order to ensure a succession. This is certainly the best plan of bleaching later in the season, when frosty nights are prevalent, for then the dried leaves afford protection to the Endive. Watch for decaying foliage on plants under pots, for this often spreads and rots the whole plant.

THE HARDY FRUIT GARDEN.

By W. A. COOK, Gardener to Sir EDMUND C. LODER, Bart., Leonardslee, Sussex.

New Strawberry plantations should now be formed, using young plants that were pegged and grown in small 60-pots in good soil. If the beds are intended to remain for two or three seasons the plants should be planted in lines 2 feet 6 inches apart, or they may be placed 15 inches apart each way for the first year; and then, when the first season's fruit is gathered, alternate rows, and every other plant in the remaining row should be removed. This practice is only to be recommended for growers with a limited area and for the purpose of securing quick returns. Plant firmly and do not allow the young plants to suffer from want of water, or they will not build up crowns sufficiently strong to carry good crops of fruits. Royal Sovereign is the variety best adapted for this annual method of culture. In making new beds of Strawberries it is advisable to place the varieties in rotation, according to their season of ripening. Late varieties should have a cooler and more exposed position in order to prolong their season. Label all the varieties prominently. Should the weather prove very hot and dry, a thin mulching of manure will be an advantage, for it will help to check evaporation of moisture. Amongst the

many varieties now in commerce, the following I have found succeed well; but it must be remembered that varieties differ according to localities and to the nature of the soil: Royal Sovereign, Fillbasket, Givon's Late Prolific, Waterloo, President Loubet, Sir Joseph Paxton, Climax, Monarch, and British Queen. Givon's Late and President Loubet have been excellent with me this season. Alpine Strawberries should now be furnishing good supplies of fruits, and the plants must be afforded plenty of moisture at their roots.

Autumn Fruiting Raspberries.—These must be afforded moisture at their roots and have their canes thinned in order to strengthen those left for fruiting. As soon as the Raspberries begin to ripen, nets must be placed over the plantation, or the birds will soon take all the fruits.

Fruit Gathering.—Proceed to gather all the fruits that are ripe and store them in the fruit room. When all are gathered, the trees should receive a good cleansing, using a wash of petroleum or nicotine soap. This operation must be done effectually, and several applications may be necessary to perfectly free the trees from pests.

Watering.—Up to the present (August 17) very little rain has fallen in this district. The weather has been exceedingly hot, and this with a drying wind has entailed a lot of watering amongst the fruit trees. A sufficiency of water is of the utmost importance in fruit-cultivation, especially where the trees are planted on walls, raised borders, &c. Trees that have fair crops of swelling fruits must be watered often and well; small quantities will not suffice.

Nets may now be removed from the main plots of Gooseberries and Red Currants, and the soil should be stirred and freed from weeds. See that the later fruiting bushes on north borders and on walls receive protection from birds and from wasps. All these latter insects should, as far as possible, be destroyed. Hunt out their nests and pour in a quantity of cyanide of potassium dissolved in boiling water. This dangerous poison must be labelled POISON, kept tightly corked, and placed under lock and key, and only entrusted to competent and responsible persons.

Young Fruit Trees that were planted late should receive every encouragement to enable them to complete their growth. See that they are well watered and the ground about them well stirred. This also applies to plantations of bush-trained fruit trees. Stirring the surface fills up the interstices in the soil and prevents excessive evaporation of moisture. All fruits when gathered should be taken to a cool fruit room.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower to Sir TREVOR LAWRENCE, Bart., Burford, Surrey.

Miltonia vexillaria and its varieties.—Plants that have commenced to grow should be examined to see it any of them require repotting. Those in a healthy state, in pots of suitable size, and in which the compost is still in a good condition, need not be disturbed, but can be left until the early days of the New Year before being disturbed. A little of the old sphagnum on the surface should, however, be removed, and some fresh living moss substituted, for this will serve as a guide when watering. Some plants may have deteriorated through excessive flowering, or from other causes; and, if they have started to grow, will require immediate attention. Turn the plants out of their pots, remove all the old compost, cut off all dead roots and decayed parts, and at the same time look carefully underneath the pseudo-bulbs for wood lice, as many of these insects are frequently to be found concealed amongst the old roots. Select pots or pans much smaller than those the plants have hitherto occupied, and three-parts fill them with drainage, over which place a thin layer of rough sphagnum moss, and then a compost consisting of three parts sphagnum-moss to one part of peat, with a little leaf soil, adding moderate quantities of small crocks and coarse silver sand, and mix the whole well together. After re-potting, water should be afforded the plants very sparingly through a fine rose-watering can, or through a fine sprayer, for only sufficient for the sphagnum to grow will be needed. With proper care, by next spring these unhealthy-looking plants will require repotting into pots at least two sizes larger than those they have occupied; keep them well shaded from sunshine until new roots are seen pushing their way through the compost, for much exposure to strong light, while they are practically rootless, will soon cause the pseudo-bulbs and leaves to shrivel. The temperature of the cool house will suit M. vexillaria until the nights become chilly, when the plants should be taken back to their former quarters in the intermediate house, and where air is freely admitted at all times. The late summer-flowering varieties, as M. v. rubella and M. v. superba, are now quite at rest. M. v. Leopoldii is in flower. All these varieties will require similar attention to that described above when growth commences afresh. The distinct hybrid M. Bleuana and its variety nobilior is in full growth and may, if necessary, be potted. It succeeds best throughout the year in a shady corner of the intermediate house.

Angræcum falcatum is now flowering in the cool house. Its small, pure white flowers emit a sweet, delicate odour, and it is well worth growing for its fragrance alone. The plant should be grown in a well-drained shallow pan, with a thin layer of sphagnum-moss to root in. It should be suspended in a shady part of the house, and should never be allowed to become dry. Promenæa citrina, P. stapelioides, and P. microptera are flowering in the same house. Being dwarf-growing plants, they should be suspended in a similar manner to the Angræcum, and be treated in every other respect in the same way as that plant. They succeed best in well-drained peat and sphagnum-moss.

Dendrobiums.—Many of these plants are now completing their season's growth, and any which are making their terminal leaf should be removed to that end of the house where plenty of air and light can be admitted, so as to prepare them for removal to cooler quarters. Afford plenty of water at their roots and well syringe the foliage on bright sunny days, so as to produce strong, plump, flowering pseudo-bulbs.

Thunias may now be placed out of doors in full sunshine in order that they may consolidate their growths and become gradually ripened. They will still require water until the leaves change colour, when moisture should be withheld altogether.

PLANTS UNDER GLASS.

By B. CROMWELL, Gardener to T. SUTTON TIMMIS, Esq., Cleveley, Allerton, Liverpool.

The Fernery.—Overhead syringing of the plants should now be discontinued, and the sun-blinds should in most cases be removed to allow a moderate amount of sunshine to reach the plants, for this, with an increased amount of ventilation, will mature and harden the fronds, rendering them the better for use in a cut state in the winter months. Adiantums which have been placed in the cool conservatory, or which have been used for decorative work in the residence, and whose fronds in consequence have become untidy, should be defoliated (after being kept somewhat dry at the roots) and then be returned to a shelf in a warm house, where they will again grow strongly and furnish new fronds before winter, at which season they will be serviceable for room decoration.

Souvenir de la Malmaison Carnations.—As soon as the layers of these plants have become rooted sever them from the parents, and in the course of a few days pot them into 4-inch pots, using a compost of good loam, leaf-mould, sand, bone-meal, and old soot. Shade the newly-potted plants from bright sunshine until the roots become active, and afford water very carefully. A weekly spraying with some fungicide such as "Carvita" will keep the plants free from fungoid diseases.

Fuchsias trained to rafters.—These plants are never seen to better advantage than when growing up the rafters of a greenhouse or a conservatory. Cuttings for this purpose should be rooted forthwith and be kept growing all through the winter. The plants must not have their leading shoots removed, but all side growths must be taken away as they appear, and this must be done until the plants have reached the bottom of the rafter, after which the development of side branches should be encouraged. A substantial and lasting compost of good loam, dried cow manure, leaf-mould, with added sand and bone-meal, should be used for their planting. By following this plan the rafters of the house will be clothed with a profusion of richly-coloured pendulous flowers and bright green leaves such as are produced by few other plants.

Coleus.—Cuttings of these decorative foliage plants should be rooted singly in small pots in the propagating pit, and when they are rooted they should be hardened off by placing them on a shelf near to the glass in a moderately warm house. Cuttings inserted after this date often root unsatisfactorily and they do not winter so well as earlier rooted plants. The soil used in their propagation should never contain manure, for if it does, the rich colours of the foliage will be entirely absent during the dull days of winter.

General Remarks.—Cuttings of Petunias, Zonal and Ivy-leaved Pelargoniums, Fuchsias, Heliotropes, and Abutilons should now be inserted. Old worthless plants of these subjects should be thrown away; their pots will be useful for growing early flowering bulbs such as Roman Hyacinths, Freesias, Narcissus, &c. Cyclamen seeds, when ripe, should be sown forthwith, they should be dibbled into seed pans or pots, 1 inch apart and ½ inch deep, and the pans placed in an intermediate temperature, which will be sufficient for the seeds to germinate.

FRUITS UNDER GLASS.

By T. W. BIRKINSHAW, Gardener to Lt.-Col. Sir CHAS. HAMILTON, Bart., Hatley Park, Bedfordshire.

Late Muscat Grapes.—It is desirable to have these Grapes in condition for as long a period as is possible, as they are always in demand, and especially the White Muscats. To keep them well, it is essential that the bunches be perfectly finished. The lateral growths should not be allowed to become crowded, and if a few only of these are removed each day, the vines will not receive any perceptible check. Some of the leaves may be tied back from bunches around which the foliage is very dense, but not so as to expose the berries to the full effects of the sun's rays or they will soon become brown, and so disfigure them. It is important that the foliage be kept in a healthy condition; precautions must therefore be taken to prevent the leaves becoming scorched. If the sun's rays are excessively hot, a garden net thrown over the glass will greatly benefit both the vines and bunches. The borders must be properly watered, for neglect in this matter will be fatal to long keeping of the bunches. Stimulants will not be required after the berries begin to colour. Outside borders situated in wet, low-lying districts must be protected from excessive rains. They should be covered with boards or with covers made of zinc. This will greatly assist the Grapes in keeping, and will help them to retain their flavour.

Figs.—Trees that are growing in permanent borders, and which are carrying a second crop of fruits, should be given every encouragement to perfect them. They should be liberally supplied with moisture at their roots, and they should be vigorously syringed in the morning and in the afternoon, in order to keep down attacks of red spider. The shoots, especially strong growths, should be regularly stopped; suckers from the base of the trees must be removed entirely, for they rob the other parts of the trees of much nourishment, and sometimes even cause the fruits to drop. The earliest pot Figs that have finished fruiting may now be taken in hand for repotting should they require it. If they are growing in large pots, the soil and roots forming the "ball" must be reduced and the plants be repotted in pots of the same size, provided with plenty of drainage, using a compost of fibrous loam and old lime rubble, with some bone meal added. Plunge the pots in ashes in the open after potting, and syringe the trees twice daily during dry weather.

Figs in Cool-Houses.—Trees that are now in bearing in structures where there is no means of artificial heating should receive every advantage of the sun's heat, and the houses should be closed early in the afternoon, in order to send the tempearture up to 75° or 80°. Borders in which are growing trees that have finished fruiting, and which appear to be in a sour condition, should be seen to at once. Commence lifting the roots at a distance of about 2 feet away from the main stem, and cut back any strong roots as the work proceeds. Replace the sour soil with new compost, that should be rammed very firmly. Syringe the trees as recommended above for pot Figs.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication *as well as specimens and plants for naming, should be addressed to the* **EDITOR**, 41, Wellington Street, Covent Garden, London. *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Special Notice to Correspondents.—*The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.*

Illustrations.—*The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c., but he cannot be responsible for loss or injury.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.*

Local News.—*Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

APPOINTMENTS FOR THE ENSUING WEEK.

SATURDAY,	Aug. 25	Gateside Fl. Sh. Gatehouse Fl. Sh. Hawick Fl. Sh. Nat. Co-operative Fl., Fruit and Veg. Sh. at the Crystal Palace.

WEDNESDAY— Ditto.
THURSDAY— Ditto.
FRIDAY— Ditto.
FRIDAY—
Imported and Established Orchids from various sources, at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 12.45.

School Gardens.

Many and varied are the branches of instruction undertaken by the various committees charged with the administration of technical education up and down the country, but we doubt if any subject taught is of greater, or even of equal utilitarian value, to that of gardening. At the end of the session the students have something tangible to see as the result of their labour and instruction. No one will deny that good work has been done in fostering a love of the craft among cottagers and allotment holders, for one has only to visit a show such as we recently attended to see the extraordinary produce of fruits, flowers, and vegetables, from allotment grounds. Similar instruction is now being, in many cases, extended to the elder boys in the village schools, and the establishment of school-gardens, such as we warmly advocated many years ago, but at the time with little effect, is now rapidly developing. One of the most active counties in this direction is Hertfordshire, whose Agricultural Education Sub-Committee has done much to advance this important subject, and in various places in the county are established school-gardens for boys between the ages of eleven and fourteen years attending the elementary schools; and also plots for older lads who are attending evening schools. The scheme is supervised by a staff lecturer, Mr. A. E. Burgess (formerly connected with the Essex County School of Horticulture), and he is assisted by several sub-instructors. In order to help forward the work special classes in horticulture and botany are established for school-teachers (many of whom, it is well known, are first-rate cultivators), so that they themselves may lend a hand in the work of instruction. The rapid increase in the work, however, has made the appointment of an additional instructor necessary, and during the present year, Mr. J. H. Walker, of Leicester, has been appointed to the western side of the county, where he has already several school gardens at work. In all the centres the boys have separate plots and the county provides tools, toolhouses, and sometimes seeds. The boys are, subject to certain restrictions, allowed to appropriate the produce of their individual plots.

One of the most important centres of the work is Cheshunt, where it was our pleasure recently to inspect the gardens, and to see the boys at work. The local council of Cheshunt has acquired a large house and grounds—the Old Manor House—for Urban District offices, etc., and the garden afforded an ideal spot for the scheme. About one acre of this garden is rented by the Technical Authorities, and it has been stocked with trees and flowers, largely through the generosity of Mr. George Paul, who takes a keen interest in the movement. Four schools take part in the work of this garden, and the number of boys attending each week is over one hundred. Each lad receives one and a half hour's instruction, somewhat as follows: Three-quarters of an hour in the Technical School attached to the ground, where he is taught the principles of horticulture, and three-quarters of an hour practical work and instruction in the garden. The garden is divided into several sections, viz., (a) General plot, consisting of flower-borders and fruit and vegetable quarters. Here the lad receives a preliminary training before being apportioned a plot to himself; (b) school plots: there are four of these, and each is divided into fourteen smaller plots, one for each boy. For the school with the best quarter is offered a Challenge Shield, presented by the nurserymen of Cheshunt. It has been won this year by the Cheshunt British School. (c) beds for the inclusion of plants of the more common families; (d) an orchard-plot, containing Apple, Pear, Plum, Medlar, Quince, and Cherry trees. These trees have been trained in various ways. More than 50 have been grafted or budded, either by the students themselves, or by the instructor for demonstration purposes. The boys can thus watch the development of a tree from the bud or graft to its final shape. The seeds are provided by the local Education Sub-Committee. The vegetables, fruit, etc., from the general plot are sold, a goodly portion being purchased by the parents of the lads attending the class. The produce of the four school gardens is, as stated, taken by the boys themselves, subject to the payment of a small sum, and they may dispose of it as they wish. No lad, however, is allowed to remove anything before it has been valued by the instructor and entered in a note-book. Thus, the boys are taught the value of a crop as well as the manner of producing it. The fifty-six plots were each carrying the same crops—Beans, Lettuce, Potatos, Carrots, Beet, Onions, and Parsnips. A crop of Peas had just been harvested, and the boys had made more than sufficient from the sale of these than the amount of their fees. The size of each plot is about thirty square yards, although in some of the centres they are from thirty-six to forty square yards. In bad weather the lads assemble in the potting-shed, where they are given suitable work.

The gardens are also used for demonstrations to the public and to the pupils of the evening classes. Cheshunt and district should be congratulated on having in their midst such a man as Mr. George Paul, to whose energy and influence the establishment of technical horticulture in the district is largely due, and through whose generosity many acceptable plants and trees have been added to the garden.

We take this opportunity also of alluding to

[*Photo by A. E. Burgess.*

FIG. 59.—A LESSON ON TRAINING FRUIT TREES IN THE SCHOOL GARDENS, CHESHUNT

the flower-beds, designed, laid out, and planted by the boys in a reformatory near Droitwich. Mr. Udale, a highly competent judge, tells us that he has visited these gardens at intervals during the last four or five years, and has been impressed with their design and the excellence of their upkeep. The soil is ordinary gravel and the gardens occupy one end of the play-ground. The designs are worked out with pebbles.

The gardens are destroyed each winter and the boys draw new designs, which are again laid out each spring and planted on the approach of summer.

The whole of the work is done by the boys without any assistance in drawing or anything else, and without any supervision.

The farm consists of about 70 acres, with workshops. Many are taught gardening, the senior boys taking the responsibility (under their foreman) for certain crops of fruit and vegetables, and each senior boy has a squad of juniors under his control. Some of the boys are taught tailoring, others boot-making. Judging from the photographs sent us by Mr. Udale, the plots are creditable to all concerned, although they show that imitation is freely practised and that a greater degree of originality should be encouraged. Several photographs were sent us; the one we reproduce is a good typical representation, not the best in our judgment, but the one most suitable for reproduction in our pages.

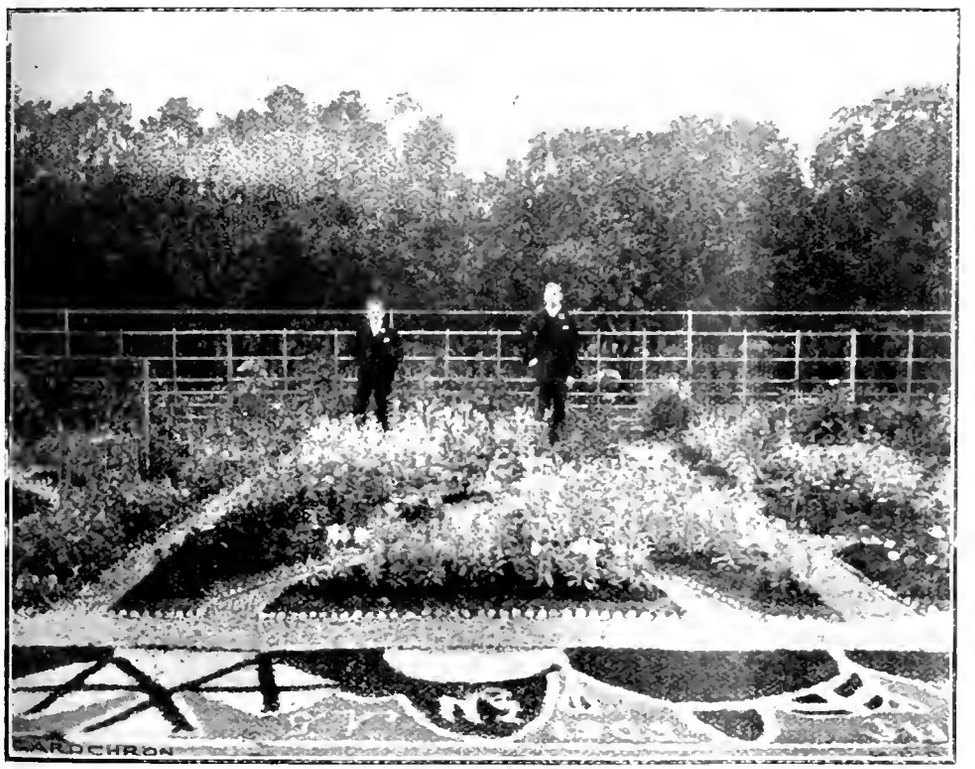

Fig. 60.—A school garden near Droitwich.

Our Supplementary Illustration (*Sobralia Amesiae* ×).—There seems to be some diversity of practice in writing the name of this plant, for whilst some write it Amesiae, as if the lady had in some way taken part in the production or introduction of the plant, others give it the complimentary name Amesiana, which leaves us in doubt whether the compliment was intended for the gentleman or for the lady! In Sanders' Orchid Hybrids, p. 115, S. Amesiae × is stated to be the product from S. xantholeuca crossed by S. T. Wilsoniana. Be this as it may, the plant is an interesting one from the peculiarity of the colouring of its flowers, which may be described as pale-buff flushed with rose. Mr. Worthington Smith's drawing was taken from a plant exhibited by Major Holford at the Horticultural Society on July 17 last.

Royal Horticultural Society.—The next meeting of the Royal Horticultural Society will take place on Tuesday, August 28. A lecture on "Meteorology in its Relation to Horticulture," illustrated by lantern slides, will be given by Mr. R. H. Curtis, F.R.M.S., at 3 o'clock.

The Royal Horticultural Society's School-Teachers' Examination in Cottage Gardening.—This annual examination of teachers in elementary schools in practical gardening knowledge took place at various centres on April 11 last. The results, as furnished by the reports of the examiners, Messrs. J. Hudson and A. Dean, show 156 passes in the three classes of excellence. In the first class are ranked 46 candidates, in the second class 58, and in the third class 52. Nothing is said as to sex or numbers of marks awarded to each candidate. The lists, arranged in order of merit, show the positions of the respective candidates. As usual, certain schools of gardening figure in the list, Swanley College having four students, all well up in the first class. Then come the County Technical School, Stafford, and the Essex and Middlesex Schools of Horticulture. These four various schools or colleges place nine candidates in the first class out of 46, 15 in the second class out of 58, and in the third class 17 out of 52, thus securing 41 passes out of 156. It is interesting to note, therefore, how many home-trained candidates have passed.

Winter Flowering Carnation Society.—A Committee meeting of this newly formed society will be held on Tuesday, August 28, at the Hotel Windsor, when the schedules and prize list of the first show will be considered. The committee appeal for help to enable them to offer suitable monetary prizes, and invite suggestions from persons not attending the meeting. The time and the place for holding the first annual exhibition is not definitely fixed, but it is suggested that the show shall be held early in December. The Hon. Sec. is Mr. Hayward Mathias, Roedown House, Medstead, Herts.

Co-operative Flower Show at the Crystal Palace.—The Co-operative Flower Show at the Crystal Palace to be held this day promises to be most successful. Upwards of 2,000 exhibits will be sent in by nearly 250 exhibitors. Many of these exhibits will be from working men.

Sale of Imperial Orchids.—It is announced in the *Evening Standard* that on or about October 1 a sale will be held in Vienna of a large surplus of very fine and rare Orchids from the imperial conservatories of Schönbrunn. Amongst them are some unique crosses and hybrids which will be likely to arouse keen competition.

Dr. Wilhelm Seelig, for many years vice-president of the German Pomological Society, died at Kiel on July 30 in his 86th year. The deceased was a native of Cassel and studied jurisprudence in Heidelberg, Berlin and Marburg. In 1871 he was elected to the Reichstag, and in 1873 as a member of the Prussian House of Parliament. He greatly interested himself in fruit culture, and was appointed deputy president of the above-named society, an office that he filled for many years; in 1899 he was made honorary president. He was founder of the Schleswig-Holstein Central Society for Horticulture and Fruit Culture.

A New Natural Order. The discovery of a new or heretofore unrecognised natural order is an event nowadays. It has fallen to the lot of Mr. W. B. Hemsley to differentiate such a group under the name of Julianaceæ, which consists of two genera and five species. Juliania is a Mexican genus of resiniferous trees with pinnate leaves and dioecious flowers. The other genus, Orthopterygium, is Peruvian. There are resemblances to the Anacardiaceæ, and to the Cupuliferæ, but Mr. Hemsley, in a communication to the Royal Society, places the group between the Juglandaceæ and the Cupuliferæ.

Plant Protection from Insects and Fungi in Saxony.—In connection with the Lead office for plant-protection in the Kingdom of Saxony, an enquiry office has been established at Dresden, to which the owners of gardens, and especially nurserymen and florists, may apply for information, and from which replies to enquiries will be made, free of charge, concerning fungi and insects injurious to plants. Gardeners are invited to send plants infested with insects or vegetable parasites, by sample post-packets, post paid, together with particulars in reference to the methods of cultivation, extension of the malady, and cause of the same, to Dr. Arno Naumann, the assistant in the experimental station for vegetable physiology, the Royal Botanical Gardens, Dresden.

Retarding Lilies of the Valley.—An English correspondent of the *Weekly Florist's Review* writes that the mistakes and consequent heavy losses in reference to the right and wrong way of retarding Lily of the Valley were very forcibly demonstrated to him lately. A batch of a million was ruined through being improperly retarded in one of the public cold stores. They had been kept at a regular 38° during the whole time, but the atmosphere was simply dry, cold air. What this plant requires is 1° to 6° of warmth, with an atmosphere that is continually more or less making ice. It should never be forgotten that there is a difference of fully 5° in the effect of moist and dry frost on both vegetable and animal life, and one of the greatest items toward success in retarding Lilies is to put them in an atmosphere heavily laden with moisture. Lilium longiflorum and other Japan Lilies will not successfully retard in a moisture-laden atmosphere.

Attempted Poisoning in British Guiana.—A Reuter message from Georgetown, British Guiana, dated July 28, states that the colony has been deeply stirred by an attempt to poison Professor J. B. Harrison, Director of Science and Agriculture and Government analyst, and with him the whole of the laboratory staff. In June Professor Harrison was incapacitated by a mysterious illness, which recurred in spite of skilled treatment. About the same time the laboratory was more than once entered by some unknown person at night. Some samples were stolen and others tampered with. The burglars were apparently possessed of duplicate keys. On July 5 Professor Harrison, after drinking several glasses of iced-water from the can in his private office, was seized with headache, giddiness, and nausea. He was compelled to leave work and go home, where he was confined to bed. Meanwhile the assistants at the laboratory and the messenger developed similar alarming symptoms after drinking iced-water from the reservoir. On the Monday it occurred to Mr. Garraway that their illness might be due to poison, and an inspection of the water receptacles showed that enough "Rough on Rats" had been placed therein to poison hundreds of people. Fortunately all the victims have nearly recovered by now, but Professor Harrison has been so ill that he has been ordered a complete change, and will probably leave the colony shortly for a prolonged holiday. So far no clue to the perpetrator of the outrage has been found.

A New Disease on New Zealand Veronicas.—We learn from a communication in the *Oesterreichische Garten Zeitung* for August that a species of fungus has been observed on Veronica speciosa and its varieties which works great havoc with the plants in the horticultural school at Eisgrub, in Moravia. It is Septoria exotica. During the summer the fungus is to be met with only occasionally, but it develops rapidly in autumn and winter when the plants are under glass. The fungus appears as small grey spots, 1-2 mm. in diameter, and specially visible on the under side of the leaves, where their presence is distinguishable from the surrounding tissues by a raised, thick line. The patches grow constantly lighter in tint, till in the course of 2 to 4 weeks they become quite white, and the leaves crippled. On these white patches there appear black spore cases, in which a great number of spores are developed. The crippling of the leaves is followed by their fall, even when the infection is merely slight, and the previously bushy plant assumes a naked appearance with but few leaves remaining. The fungus has been observed in Argentina, Italy, and Berlin. The application of the ammoniacal copper-soda mixture is recommended as a remedy.

The Influence of the Graft on the Rooting of the Pear.—The question of the influence of the grafted ennobled variety on the wilding or other kind of stock has not of late years been so much discussed by cultivators or pomologists as it deserves to be, more particularly for standard trees. There are certain varieties of Pears which, under the most diverse conditions of soil and climate, exert a great influence on the root system in the direction of increasing considerably the number of the roots. As is well known, the Pear trees which make weak top growth and spare foliage are mostly deficient in roots, but this unsatisfactory state of things can be entirely averted and altered for the better by the employment of a freer-growing variety as first graft or bud, upon which any desired variety may be worked the following year, a practice commonly followed in fruit nurseries with certain varieties of Pears that are worked on the Quince stock. Perhaps some of the readers of this note will kindly communicate facts touching on this interesting subject, not exclusively confining them to the Pear.

Threatened Destruction of Bostall Woods.—Mr. A. D. Webster writes:—"This beautiful Pine woodland, near Plumstead, has been sadly damaged of late years by the ravages of the Pine beetle (Hylurgus piniperda). Fully five years ago I pointed out in the *Timber Trades Journal* the then threatened destruction, and suggested means of coping with the evil, but nothing was done. Since then many fine trees have been killed out and others are in imminent danger of succumbing to the attacks of this dreaded pest of our woodlands. Not only should the dead and dying trees be at once cut down, but all woodland *débris*, including fallen branches and the roots of trees which have been left in the ground, must be destroyed. The life history of the insect teaches us much regarding the best methods of destruction or, at least, of keeping it in bounds."

White Ants Beaten at Last.—It is announced that the great scourge known as white ants or termites, which destroy so ruthlessly all descriptions of woodwork, from railway sleepers to household furniture, in tropical and subtropical lands, can now be effectually dealt with, as, by a newly discovered process, any wood can readily be rendered impervious to their attacks. Attempts have been made hitherto to combat these pests by various means, but until now either the means have proved unsuccessful or the odour of the preservative used has been so pungent as to preclude its employment for constructional timbers or for furniture. It has been claimed that some woods, such as Indian Teak, Australian Cypress, Pine, and Turpentine Wood, in their natural state are more or less immune from attack, but the evidence in favour of their total immunity is often so contradictory that the conclusion can only be drawn that much depends on the ground in which the trees are grown, and the species of termite to whose voracity the wood is afterwards exposed. Mr. Saville Kent points out in his very able chapter on Australian Termitidae that Jarrah (Eucalyptus marginata) grown on the Ironstone ranges is practically proof, while that grown elsewhere is by no means so. Again, some species of white ants display a decided preference for certain woods; for instance, the Calotermes domesticus of the Malay Peninsula, while rarely touching woods of a piney or resinous nature, readily attack other timbers, especially those grown locally. An illustration before us represents two pieces of ordinary yellow deal, a most toothsome morsel to nearly every variety of white ants. These pieces were bolted together, and placed by Mr. H. N. Ridley, Director of the Government Botanical Gardens, Singapore, some months ago in a position where termites abounded. The untouched piece had been treated in London by the Powell wood-process with a termite-resisting solution, which is absolutely odourless and innocuous except to insects, while the other was left in its natural condition. The latter has been almost entirely consumed, while the former remains intact. The specimens were removed before the natural piece had been entirely consumed, as had been the case in other places. This discovery is naturally of great importance to dwellers in the tropics, and especially to timber merchants, furniture manufacturers, &c., who trade with tropical countries, for merchants will now be able to guarantee all prepared wood against destruction by termites. Curiously enough, the process, which only occupies a few hours, actually improves the appearance of the wood, which at the same time is effectually seasoned and rendered proof against dry rot and similar fungoid growths. The cost, too, is said to be low. Particulars can be had free from the Secretary, Powell Wood-Process Syndicate, 28, Fleet Street, E.C.

Influence of the Stock upon the Scion.—Continuing their investigations upon the results produced by grafting in various ways, MM. G. Rivière and G. Bailhache contribute a further paper on the subject to the *Comptes Rendus* for April 2. Their past researches bore special reference to fruit trees, and were chiefly directed to the different effects upon the Pears Triomphe de Jodoigne and Doyenné d'hiver, produced by grafting them upon the free-stock and upon the Quince. The more recent experiments were made with Apples, to see if, with these, as with the Pears, the exterior characteristics as well as the chemical composition were modified according to the stock upon which they were grafted. In 1905 the investigators made an analysis of ripe Apples of the variety Calville Blanc gathered from trees grafted, some upon the Paradise stock, others upon the Doucin. All these trees were of the same age (14 years), and growing under identical conditions. They were planted side by side in the same plot and trained in the same form; further, the wall against which they were growing faced the east. Neither the composition of the soil, the aspect, nor the age of the trees by which the size and quality of the fruits are generally influenced could affect them in the new experiments. The stock could be considered, under these circumstances, as the sole factor capable of exercising any influence on the graft, and above all, on its developments. The results obtained are summarised thus: 1. The average weight of Apples gathered from Calville Blanc, grafted upon the Paradise stock, exceeded that of fruit of the same variety grafted upon the Doucin. 2. The proportion of free acid (represented as sulphuric acid) was greater in the juice of Apples grafted upon the Paradise than in that of these fruits on a plant grafted on the Doucin. 3. The proportion of ash is higher in the juice of fruit from trees grafted on the Doucin than in that of fruit gathered from trees grown on the Paradise. 4. The proportions of glucose and reduction-sugar, and of saccharose, are notably greater in fruits of Calville Blanc grafted on Paradise than in those of the same variety from trees grafted on the Doucin. Therefore, these experiments plainly confirm those published in 1897, and seem, further, to demonstrate that not only do the dessert Apples contain more sugar in each litre of juice than do the Pears, but also that they contain more saccharose and more free acid.

Fruit Culture in Gloucestershire.—The annual report of the Lecturer on Horticulture to the Gloucestershire County Council (Mr. G. H. Hollingworth, F.R.H.S.) states that the applications for lectures last winter were so numerous that a large number had to be placed on the reserve list. There is, he says, no lack of evidence to prove that Gloucestershire is naturally adapted for fruit culture, and the many old orchards in the county indicate that the possibilities in this direction were fully realised by a generation of growers in the past. Some ground has doubtless been lost, but the outlook is hopeful, and agriculturists are becoming alive to the fact that if the orchard is to be made profitable it must have the same care as is bestowed on any other department on the farm. Every year, thanks to the instruction given by the County Council, growers realise more and more the necessity of planting good trees of recognised varieties, keeping them clean, and attending to the important items of pruning, protecting, and manuring. Hundreds of trees have been planted during the past winter, and hundreds of others, planted previously, are coming into a state of bearing. In due course the result of this awakening up must be seen, and he hopes Gloucestershire will uphold its time-honoured reputation as one of the leading fruit-growing counties in the West of England.

Willows.—The difficulty of determining the species and varieties of Willows is well-known to all who have made the attempt. The labour will be much facilitated by a publication of which we find mention in the *Bulletin* of the Botanical Society of France (1906), p. 412. It appears that Mdlle. A. Camus and M. G. Camus have just published a list of all the European species and varieties, with analytical tables and illustrations. Anatomical characters are made use of for purposes of discrimination such as the presence or absence of stomates on the upper surface of the leaves, the form of the midrib as seen in section, the presence or absence of wax in the rind of the branches, the structure of the vascular bundles, and of the pith and other points serviceable in the laboratory, but not adapted for use in the field. Very numerous hybrids and some of complex origin are described.

"The Garden, You, and I."—By Barbara, Author of "The Garden of a Commuter's Wife," &c. (New York: The Macmillan Company. London: Macmillan & Co., Ltd.). We can recommend this book to all who like to read about other people and their gardening experiences, "Barbara" writes pleasantly of her American home and her plantations, and her remarks may prove useful, though we agree with her that "one must live the outdoor life of her own locality to get the best results in a garden." The title of the book is awkward, and it takes some time to understand that "You" is a female friend of the author, introduced to serve as a convenient correspondent, sending and receiving long and rather wordy letters about gardens and miscellaneous matters also. The private affairs of the characters have no horticultural interest, but readers for this class of book appear to be insatiable, so should appreciate the present volume and admire the illustrations. There is no doubt as to "Barbara's" fondness for gardening, and she tries to be of practical use, and has drawn up a list of hardy seeds and worthy annuals.

Experiments with Calcium Cyanimide.—In the July number of the *Journal of the Board of Agriculture* Mr. A. D. Hall details the results of experiments with calcium cyanimide used in 1905 at the Rothamsted Experimental Station for Barley and Mangels. The new manure is obtained by effective combination of calcium carbide with the nitrogen of the atmosphere. As regards Mangels, the seed was Yellow Globe, sowing taking place on May 10. The seed grew well from the start, and there was an even plant with no misses. The crop was lifted on October 20th. "Taking the results together and also considering those obtained in 1904, it is clear that the nitrogen in calcium cyanimide is practically of the same value as that in sulphate of ammonia. There is a slight balance of evidence in favour of the sulphate of ammonia, which is chiefly manifested in the early stages of the growth of the crop, probably because the cyanimide is a little slower in coming into action, but the differences in the results are small and within the range of errors of experiment. Again, the Rothamsted soil is fairly well supplied with carbonate of lime, hence the sulphate of ammonia can exert its proper action, while no benefit is derived from the carbonate of lime which is produced in the soil from the cyanimide. The cost of production of cyanimide can only be settled when it has been put on the market on a commercial scale; it may, however, be taken as certain that if the manure can be sold on a parity with, or a little cheaper than, sulphate of ammonia, it may be employed by farmers on a large scale with every confidence of a good result." This is the more important as it tends to relieve the cultivator of the risk of exhausting the supply of available nitrogen. If it can be obtained from the atmosphere, there need be no fear of the supply running short.

Insect Pests of the Farm and Garden, by F. Martin Duncan (Swan, Sonnenschein and Co). An excellent little handbook to the knowledge of insects so far as they concern the cultivator. The introductory chapter is devoted to the details of insect structure and classification, which are lucidly explained. The following chapter is devoted to remedial measures such as spraying, and then the author proceeds to details concerning the various orders of insects, the mites, beetles, flies, aphides, bugs, scale insects, bees, saw-flies, wasps, butterflies and moths, and lastly thrips. As the book only contains 143 pages it is evident that the author has had to make a selection from among the insect pests, and has by no means included all that might have been enumerated. The book, therefore, may be looked upon as an introductory treatise illustrated by prominent examples rather than as a text-book. The descriptions are so clearly written and the illustrations so useful that we can but commend the book to the notice of students and lecturers.

Revolution in Greenhouse Building.—We take the following extract from a Guernsey paper:—"Something unique for Guernsey in the way of greenhouses may be seen at the Ramée Vineries, La Ramée. This is one of Bodegom's patent cement (reinforced concrete) structures. The cement house has, it is alleged, every advantage and no disadvantage as compared to the usual structure of wood. It helps to keep the plants free from disease, because there is an absence of crevices in which plant pests can escape from the fumigant, the only wood used being in the door and the lights. The framework of the house is more rigid, though slighter in construction, than one of wood, and this admits of a greater proportionate area of glass and gives a better lighted house, the difference in this respect between the cement house and the ordinary greenhouse being most marked. The building, consisting of iron wire covered with cement, is claimed to be practically everlasting, and its upkeep is trifling, whitewash alone being used to freshen its appearance. Finally, on the score of expense, the cement house can be built more cheaply than one of wood."

COLONIAL NOTE.

CAPE ALOES.

The Aloes are nearly over in the locality of Algoa Bay, but they have afforded a glorious sight. Those who have seen a wide expanse of the bush covered with Aloes in full bloom will readily acknowledge that it is a sight never to be forgotten. How picturesquely they stand above the surrounding herbage, according to species, with the various other plants at that time flowering!

Here, near a dwelling, some admirer has dropped a few seeds. One sees a species of Ipomœa, or, as it is more frequently called, Morning Glory, intertwined amongst other floral beauties; perhaps some of the golden Senecios, which are so abundant and in great variety, all mingling and flowering together about the tall Aloe pluridens, which is the principal species in the spot where my thoughts have now wandered. This Aloe may here be seen in many thousands. Sometimes one sees a form with yellow flowers, instead of the dull red usual to the species, which greatly adds to the colour effect of the scene.

Mr. Chabaud, to whom the property belongs, is ever willing to take any lover of the native flora to see the glorious sight during the Cape winter. A visitor would spend here a pleasant half-an-hour, for the Cape flora has no champion more enthusiastic and one who takes more special interest in this beautiful and interesting genus of the natural order Liliaceæ.

It is a pity they are not more appreciated in England. With what gratification do the visitors from the Aloe's home look over the genus in the succulent house at Kew, and how pleased they are to relate, when looking through their own collection, that this species is growing at Kew, and so forth! What a pity Cape Colony cannot have a botanical, a real botanical, garden of its own, so that all the species of the genus might be found in one place, and that open to the public. *Harry Rabjohn, August 3, 1906.*

THE IMPERIAL BIOLOGICAL INSTITUTION FOR AGRICULTURE AND FORESTRY AT DAHLEM, GERMANY.

The origin of this State-supported institute was due in the first place to the needs of agriculture, and has attained an increasing significance for horticulture. The establishment of the institution was due to the initiative of Dr. Schulz-Lupitz, a well-known agriculturist and member of the Reichstag, who brought in the following motion on March 24, 1897:—"The Reichstag shall determine to request the united Governments to establish an agricultural technical institute for bacteriology and phytopathology, and afford the requisite means from the public purse for the carrying on of the work." The fact that agriculture, forestry, and horticulture suffered heavy losses from plant-diseases, and that means and methods were needed in order to prevent and avoid them; the importance which certain bacteria have for cultivated plants, especially for the Leguminosæ, and in effecting changes in the nature of manures and soils afforded the chief reasons for Dr. Schulz-Lupitz's proposal. In February, the following year, the Reichsgesundheit Office instituted a commission, consisting of men eminent in science and practical work, to discuss the ground lines for the organisation and scope of the project; and in the same year the money grant was sanctioned, and with but little delay the institution was established, not, however, as an independent authority, but as the biological department of the Reichsgesundheit Office (Office of Health). This department dealt with matters which would fall within the purview of the newly-created body—for example, the protection of the Grape vine against the Reblaus (phylloxera), which had engaged its attention for many years, and for this reason the union of the new with the older body seemed to be desirable. In April, 1905, the separation of the biological section from the older office was effected, and the scope of the work was thereupon greatly enlarged, so as to include the study of the injurious insects, and of the epidemics among plants brought about by migratory insects, the depredations caused by mice, crows, marmots, etc., phanerogamic parasites, fungi, and other micro-organisms injurious to plant life; further, animal and vegetable organisms which are of use in the growth of plants and those which are destructive of those organism. It is in this field of research that scientific work is so useful to the cultivator. The action of nitrates in the soil, and of destructive bacteria, and the bacteriology of manures; in particular, that of stable manure is still only partially understood, and needs further elucidation.

Researches are being carried out regarding injury caused by smoke, and the gaseous products emitted by smelting works. Bee and fish culture will be investigated, and on such matters science will be found capable of affording considerable assistance to practical men. The new institution will further take an interest in the provincial institutes by making foreign

and home literature easily accessible, and eventually by acting as an organ of reference in regard to the various subjects engaging its attention.

It is intended that there should be annual conferences, to which the principals of the provincial institutes, members of scientific societies, horticulturists, and agriculturists will be invited, and who will afford the required connection of scientific activity and practical affairs. The director of the institute is Dr. Rudolf Aderhold, formerly president of the botanical department of the research station of the Royal Pomological Institute at Proskau, in Silesia. *Gartenwelt.*

looking leaves. It is planted in the American garden in heavy soil, to which have been added equal parts of peat and cow-manure. The plant is about 8 feet high.

BIGNONIA GRANDIFLORA.

This handsome climber is now flowering on a south wall of the mansion at Leonardslee. Some of the larger bunches have as many as from 40 to 50 flower buds, some of which are already expanded. The plant is exceedingly ornamental and beautiful, especially when the flowers are seen in such profusion.

ARALIA MANCHURICA.

This Manchurian plant is always attractive

the Holland House Show, July 10, 1906. It is one of the largest, if not the largest, hybrid Odontoglossum yet named. Being a secondary cross (crispum × crispo-Harryanum), it seemed likely that its size would have been reduced, but the reverse is the case. The plant had four fine pseudo-bulbs and 13 blooms; there was no disbudding needed to produce a large flower. The accompanying reproduction (fig. 61) is an exact life-size picture. I measured and recorded another of the blooms, but owing to the heat during the two days of the show and to the fact of the blooms having been cut several days before being photographed, it had lost some of its form, and had shrivelled somewhat as silk

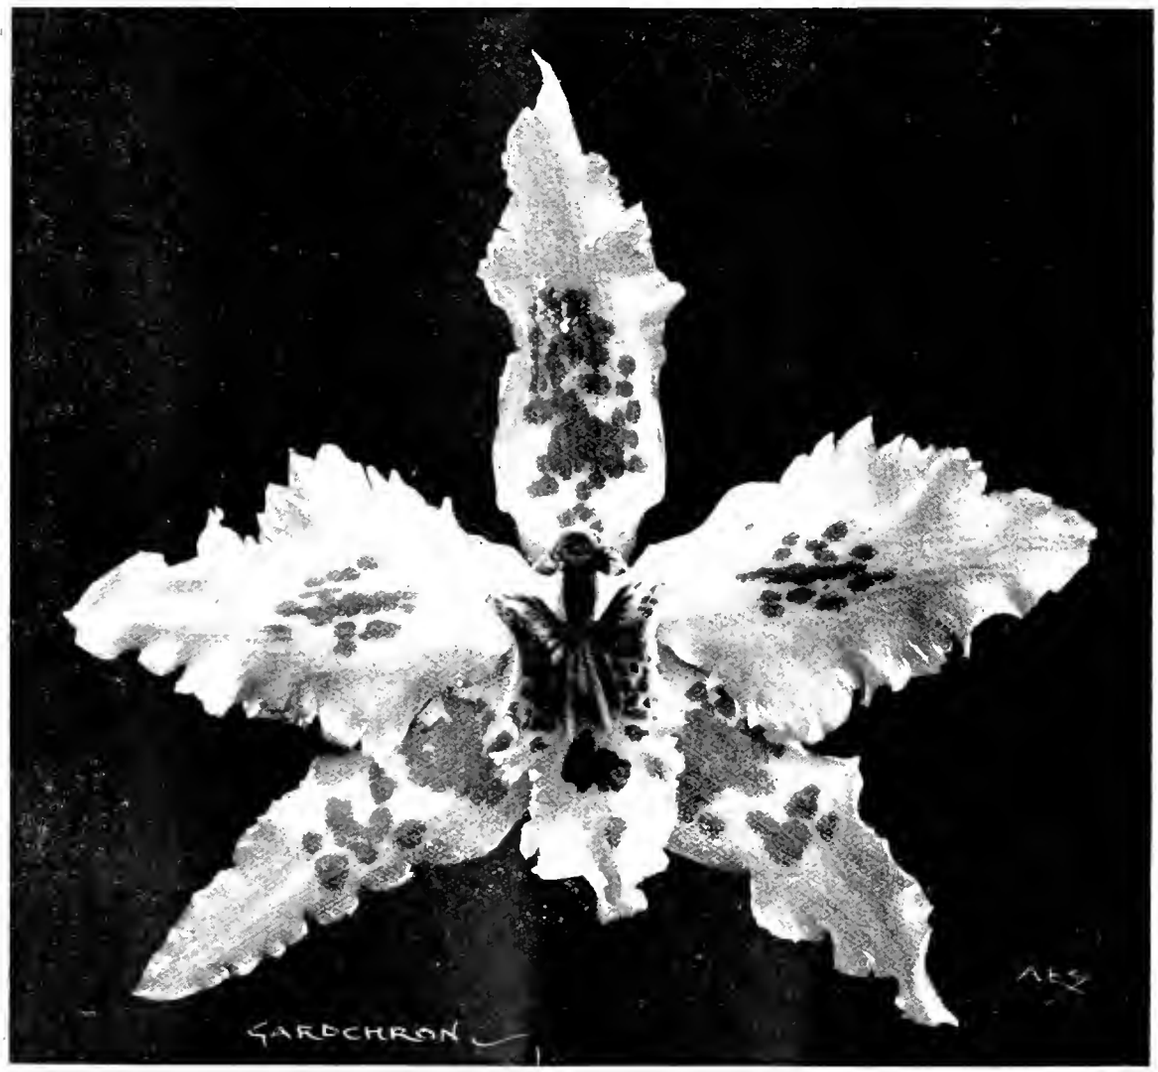

Photo by J. Gregory.

Fig. 61.—Odontoglossum amabile "Royal Sovereign": natural size.

PLANT NOTES.

ROSE ETOILE DE FRANCE.

This beautiful variety forms an excellent autumn flowering Rose, though it is not so robust as one could desire. The colour seen in its petals should ensure it a place wherever Roses are grown. H.P. Roses are badly mildewed this autumn in spite of so-called destroyers having being freely used. I am of opinion that preventatives are better than cures, and if the plants are freely supplied with water and are given liberal syringings in hot weather, they will act as a preventative against fungus.

EUGENIA APICULATA.

This is now in bloom in a sheltered border and is very effective and pretty. The white flowers are well set off by the pretty dark green, myrtle-

either planted in the American garden or in the shrubbery, its palm-like foliage rendering it a very conspicuous object. The flowers are a creamy white, and they are borne in large umbellate racemes, which generally face the sunny side, owing to the weight of the truss. When in flower the foliage often turns a beautiful red tint, forming an additional attraction. It will succeed in almost any soil, though the better the soil the more robust and beautiful will it grow. The ground should be trenched and some cow-manure and leaf-soil added. When the plant is well established its tropical appearance is the more pronounced. *W. C. Cook.*

ODONTOGLOSSUM AMABILE "ROYAL SOVEREIGN."

This extraordinarily large variety of Odontoglossum was shown by Messrs. Sander & Sons, at

having its edges rubbed. The flower is very thick in substance; the ground colour is creamy white, all its markings being violet brown. The influence of O. crispum upon the hybrid is remarkably strong in that the heavy markings have been reduced to spots, except in the sepals, and even then the usual three bar blotches and marginal markings are much suppressed. The shape of the lip has even been broken down from the oblong form of O. Harryanum to the lanceolate shape of that of O. crispum. Reversion has been at work in this case as is clear from a glance.

This plant failed to get even an Award of Merit. This shows that at certain times the higher standard needed for the Odontoglossums of the future will have to be almost beyond present expectations if such things are passed by. Perhaps this may be the "ordinary size" of the future creations. *A. B. Crawshay.*

A GOOD CROP OF MELONS.

For the opportunity of illustrating the house of Melons (fig. 62), at Buxted Park Gardens, Uckfield, Sussex, we are indebted to the gardener, Mr. Thos. Field, who writes:—"The accompanying photograph was taken on May 15 last, and it illustrates the crop of Melons grown on 10 plants. The plants were raised from seed sown during the second week of January. They were planted in the house on February 6. The first ripe fruit was cut on May 10, the variety being Ringleader, the last, Windsor Castle, on June 24. The crop comprised some 64 Melons, some of which weighed as much as 10½ lbs. each. The varieties grown were Ringleader, Jubilee, Windsor Castle, British Queen, Earl's Favourite, and Blenheim Orange."

KEW NOTES.

GESNERA CARDINALIS.

This showy plant is less popular in gardens than it was a few years ago. This is to be regretted, for it is a very useful greenhouse subject.

The flowers, which are long and tubular, are bright scarlet in colour, and the velvety green leaves are also very handsome. The plant attains a height of from 6 inches to a foot, the growths terminating in clusters of flowers. The tuber is distinct, being more solid than that of the majority of Gesneras. The plants are readily raised from seeds. A batch of seedlings now flowering in No. 4 greenhouse furnish a very bright group. Slight variation is noticeable in the flowers, the colour being more intense in some than in others. By careful management they can be had in flower at almost any season, for they can be started into growth at different times. When growing they require a fairly brisk, moist heat, but they should be transferred to a cooler house when in flower. This plant is sometimes met with in gardens under the name of G. macrantha, and it is also known as Dircaea cardinalis.

LILIUM PHILADELPHICUM.

This is one of the upright flowering species. According to the *Botanical Magazine*, where it is figured tab. 519, it was first sent to this country by Mr. John Bartram, of Philadelphia, in 1759, to Mr. Philip Miller, but although so long known to cultivation it is not often met with in gardens.

It has a rather wide geographical distribution over the Northern United States of America and Canada, where it grows in open woods, apparently preferring shelter with but little if any shade.

A number of plants are now in flower in the American garden, where it was planted several years ago in a bed of Cupressus filifera aurea. The shelter afforded by the foliage of the latter protects the Liliums from late spring frosts, and also prevents the soil from becoming parched by the sun.

The flowering season is at the end of July and the beginning of August. The slender stems are 1 foot to 2 feet in height; the leaves are usually found in whorls, but solitary leaves are sometimes found on the stems. The terminal flowers are solitary or 2 to 4 together in an umbel. The flowers, averaging 3 inches across, have orange red segments spotted with purple near their base. They vary somewhat in shade of colour, but I have not seen a flower quite so dark as that illustrated in the *Botanical Magazine*. Each segment is distinctly stalked.

DABEOCIA POLIFOLIA VAR. ALBA.

This is the white form of the St. Dabeoc's Heath, an evergreen shrub 1 to 2 feet in height, native of south-western Europe and one or two localities in Ireland. The foliage is small dark-green above and white beneath; the flowers are drooping, terminal in loose racemes. A circular bed in the American garden is covered with its pearly-white flowers, which viewed from the Palm-house Terrace presents a pleasing object.

The Dabeocias have a Heath-like appearance, and they belong to the same natural order as these plants—Ericaceæ. The flowering season extends from June to late autumn, the plant being at its best condition at the end of July and the beginning of August.

Propagation is effected by layers or cuttings inserted in autumn and by seeds. The soil in which they are grown should consist mainly of sandy peat with the addition of a little loam. Like most other members of the Ericaceæ, they will not grow if lime is present in the soil. *D. D.*

NOTICES OF BOOKS.

The Book of Market Gardening. By R. Lewis Castle. Published by John Lane, The Bodley Head, Vigo Street, London, and New York, by the John Lane Co. Price, 2s. 6d. net.

Viewed in reference to the action of the Board of Agriculture and the Local Government Board at the present time, we must regard the publication of this little work by so experienced an expert as the author as being most opportune, and we trust that it will be widely read by the persons to whom its teaching will be of the utmost value, likewise by the members of the two Boards.

With matters of cultivation it does not concern itself at all; these being generally understood by market gardeners, and to a certain extent by professional gardeners; but it is crammed with information concisely stated, gained in the school of practical market gardening in various parts of the country; as for instance, at the Neville Court gardens and nurseries, the Duke of Bedford's fruit farm, Ridgemont, and Hampton Park farm. The author was the recipient of a prize, given by the Royal Horticultural Society, of Dr. Hogg's silver medal for an essay on "grading and packing fruits and vegetables," and of the gold medal of the Fruiterers' Company. So much for his credentials.

The book begins naturally with a chapter on the selection of land, giving the current prices per acre, and the conditions which determine them. There are under this heading sub-chapters on land-tenure, compensation, situation and accessibility, special districts, soil, aspects, and altitude. Then come chapters on labour questions and difficulties, and under these the connection existing with these of cottage erection. Crops, methods and management are duly noted, in reference more especially to specialisation, showing how gigantic businesses have been created in the production of Grapes, Cucumbers, or Tomatos among glasshouse fruits; Roses, Chrysanthemums, or Daffodils amongst flowers; Celery, Onions, Asparagus, Cabbages, Cauliflowers, Brussels Sprouts, or Potatos among vegetables; and Apples, Pears, Strawberries, Currants, or Gooseberries amongst hardy fruits, and such exceptional crops as Mushrooms. Hardy bush fruits, as befits their importance to the community, are shown to be indispensable, and they should always be grown in conjunction with the cultivation of vegetables and flowers, Strawberries being regarded by the author as the best paying crop in one place; in another, Currants or Gooseberries, success with these being more certain than with Apples, Plums, Cherries, or Pears. According to the Board of Agriculture Committee, the total approximate area under fruit culture in Great Britain amounts to about 300,000 acres. Economy in production is a point greatly insisted upon, but at the same time false economy is deprecated as being often the cause of loss instead of gain, that which appeared as extravagant expenditure in developing, or organisation of a business, resulting ultimately in gains out of all proportion to the outlay. There is a useful chapter on cultivation with the aid of glass, touching on temperature, ventilation, water supply, sunlight and sunheat, insects and diseases.

Then come remarks on kinds and varieties, variety trials; the official trials of the Royal Horticultural Society and the exhibits at the fortnightly meetings of this society being referred to, as well as the trials of some of the County Councils. The preparation of produce for sale, the gathering and collection of flowers, vegetables and fruit, grading for profit, the forms of baskets, crates, boxes, the methods of packing, &c., come in for due notice, the remarks being appropriate and useful. There is, in fact, scarcely a subject connected with the business of the market grower which is omitted.

The chapters on co-operation, assessment, taxes, rates, compensation and insurance, fruit preserving and crop returns, values and profits, with which the book closes, show an intimate knowledge of the subject.

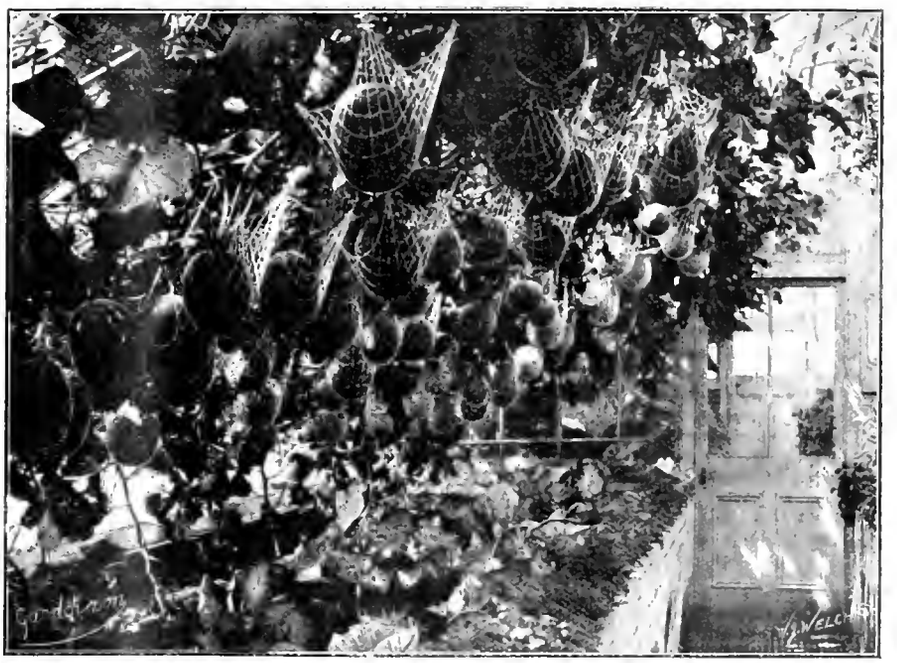

Fig. 62.—Melon house at Buxted Park Gardens.

HOME CORRESPONDENCE.

The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

Flowers at Kensington.—Visitors to Kensington Gardens should be careful not to miss the gay show of flowers on the south and east fronts of the palace. The beds have been particularly bright this summer, and some of the varieties of plants employed to make a very fine effect are worth noting. At the same time one cannot help observing that in one or two instances the combination of colour has not been particularly pleasing, and it is a pity that one or two little faults of this kind should have been permitted to creep in and mar to some extent an otherwise fine example of ornamental gardening. At Kensington they still appear to be conservative in the matter of bedding plants, for the good old-fashioned zonal Pelargonium still holds pride of place, and no such innovations as Begonias or Verbenas are used for bedding. All the principal borders are planted with Pelargoniums, of which a grand scarlet, Paul Crampel, is the most prominent. This is a splendid variety for bedding, being particularly free in habit and bearing immense trusses of a brilliant scarlet. Another good variety is Phyllis, a profuse bloomer of a bright pink hue, its one fault being that it seeds too freely and therefore soon begins to look untidy, unless it has constant attention. Rose of Allandale is, perhaps, best described as a magenta pink of a trailing habit and almost like ivy-leaved Pelargoniums in some respects. It is certainly a taking variety. A good deep scarlet is provided in Mrs. H. Cannell, although beyond its colour there is nothing very striking about this Pelargonium. With Phyllis, already mentioned, this variety would probably do better in a less hot summer. Last of all we come to two varieties which the palace gardeners might very well have omitted from their list—Dr. Nansen, a white with very poor straggly blooms, and Mrs. Wright, a hideous magenta-coloured flower with nothing at all to recommend it. These two varieties are planted in mixture, and they form quite the worst bed of the whole collection. The magenta goes badly also with the pinks and scarlets near at hand, and might with advantage have been dispensed with. In other borders a good effect is obtained with Coleus in variety and Abutilons, the latter forming a good centre in groups of four or five in small circular beds. A striking feature of the gardens is the long border on the western side of the south lawn facing east. This is a wild mixture of Sweet Peas, Stocks, Canterbury Bells, Violas, and many other old-fashioned flowers, the whole forming a very effective display against a background of flowering shrubs and dark evergreens. *East Sussex.*

Catalpa bignonioides.—Among other examples of beautiful flowering trees seen growing in Hampstead are several fine Catalpas. One in John Street has, during the last few days, become covered with a profusion of lovely blossoms, and it forms a feature in this picturesque old street of Hampstead. The Catalpa is deciduous, but after the leaves have fallen the long, slender fruit-pods remain and give a curious appearance throughout the winter to its leafless branches. A very fine specimen may be seen in the Marylebone Road; another in Harrington Square, Hampstead Road, while others are met with in some of the dusty and most fog begrimed places of the metropolis. In Gray's Inn Gardens are two of these trees. It is said by some—disputed by others—that the older was the first specimen imported into England, having been brought over from America by Sir Walter Raleigh during the reign of Queen Elizabeth. The larger and finer of the two is an offshoot from its aged parent, and is about 50 years old. The finest Catalpa tree known in this country stands in the Courtyard at Claydon House, Bucks. Some years ago this exceedingly handsome tree took the first prize as being the largest of its kind, as well as the most symmetrical in appearance. The loose spikes of flowers resemble the inflorescence of a Foxglove, and like that flower the corolla is beautifully spotted. The flowers have scarcely any calyx, and in their shape they resemble the globular flowers of the Figwort—Scrophularia nodosa—and the order Bignonaceæ, to which it belongs, is closely allied to the Scrophularineæ. The Tulip tree—Liriodendron tulipifera—has this season presented a more beautiful appearance than for years past. *James E. Whiting, 41, Heath Street, Hampstead, N.W.*

Peach Thames Bank.—Mr. Ward alludes to this excellent late yellow fleshed variety in his article upon Peach culture, p. 127. It was raised by the late Mr. Rust previous to his taking charge of Eridge Castle Gardens. We used to grow it in these gardens, but lost the tree and failed to secure another. I should be glad to hear that young trees of this variety are still to be had. *T. Coomber, The Hendre Gardens, Monmouth.*

The Rock Garden at Kew in June.—At every season of the year there is much to interest the flower-lover in the Royal Gardens, Kew. By whatever section of floriculture the visitor is especially attracted, he will find an object lesson in its treatment and in the wealth of species and forms present in these gardens. On entering the gardens early in June it is difficult to decide whither to direct the steps, such beauties are to be admired on every hand, but, to those whose bent lies in the direction of the cultivation of Alpines and such-like plants, the skilfully laid out rock garden will prove the special lodestar. Though during a period of several months this portion of the grounds will well repay a visit, it is perhaps at the season of which I write that it is at its brightest with innumerable floral treasures. In the moist peat bed beneath the perpendicular rock-work, in the crevices of which flourish Ramondia pyrenaica and its white form, with other species, and Haberlea rhodopensis, a fine collection of the Meconopsis genus was in bloom, including the bright yellow M. integrifolia, the purple-blue M. racemosa, M. aculeata, pale purple with a tinge of red in the petals, the well-known M. Wallichi and M. punicea, 2 feet 6 inches in height, with drooping, crimson flowers about 6 inches across. In the same bed were growing Primula Cockburniana, with glowing orange flowers, P. deflexa, over 2 feet in height, bearing a crowded head of small purple blossoms with white centres, and Ourisia coccinea, as well as Cypripediums in variety. A little distance away was growing a fine plant of the handsome Rodgersia podophylla, with the newer R. æsculifolia, R. pinnata and R. p. alba in close proximity. A fine collection of Saxifrages was in flower, comprising S. valdensis, S. lantoscana superba, S. cochlearis, S. lingulata, S. Hostii, S. Portæ, S. Macnabiana, S. vochinensis, S. cartilaginea, S. Wallacei, S. Geum gracilis, S. trifurcata, many varieties of S. aizoon and other hybrids. Amongst other flowers in bloom were Campanula thyrsoides, with greenish white blossoms, the slender-growing C. Steveni, Dianthus callizonus in fine bloom, D. nitidus, D. fragrans, Oncsma echioides, O. sericeum, with pale, yellowish white flowers. The single scarlet Ranunculus asiaticus, a beautiful flower, unfortunately unknown in gardens, the scarlet Delphinium nudicaule, Dicentra eximia and D. formosa, Edelweiss, the lavender-blue Iris tridentata, Dodecatheon Meadia and its white variety, Anemone palmata alba, A. polyantha, A. Regeliana, Æthionema cordatum and others, Eremuri, Gentiana verna, Eomecon chionanthum, Galax aphylla, throwing up bud, Linum arboreum, a mass of yellow, the fine Ornithogalum arcuatum, not so tall as usual, Oxalis enneaphylla, Paradisea (Anthericum) liliastrum, the blue flowered Pentstemon humilis, Senecio aurantiacus, with small orange flowers, and Lonicera pyrenaica, bearing greenish white blossoms. *S. W. F.*

Peach Culture Out-of-Doors.—I have no doubt but that most readers will agree with Mr. Ward as regards the methods of planting, &c. But I was surprised he did not mention the "Blister" disease that has caused great damage to the trees during the past few seasons, and which has, I think, been the reason why many growers have largely abandoned planting Peach trees outside. I have not up to the present found a remedy for this complaint. The trees are always well netted at the critical time, but in spite of all precautions the last few seasons' results have been very disappointing in *North Devon.*

Beech Trees and Lightning.—I have always heard since boyhood that Beech trees were immune from strokes by lightning and I think the following facts will bear this out: At Lee Moor, in the parish of Shaugh, Devon, during the month of June, 1902, a clump of Scots Fir, among which were four Beech trees, was struck by lightning during a heavy thunderstorm with the result that all the Fir trees were killed, but not one of the Beech trees was injured. I think this is sufficient proof that lightning has no effect upon Beech trees. *T. Martin, Trevabyn, Plympton, Devon.*—[One instance can hardly be deemed "sufficient." Some of our readers can perhaps supply others.—Ed.]

Kochia scoparia.—It may not generally be known that the pyramidal specimens of this plant which one sees in the London parks have been made to assume this form by cutting back the side-shoots with a knife or with a pair of small shears. Specimens grown in this manner differ greatly in appearance from plants which have been grown with insufficient space between the shoots. Some growers, whose plants have not been trimmed into shape in their earlier stages of growth, are inclined to grumble if stiff flowering shoots are produced, and in some cases it has been stated that the plants which they have grown as Kochia scoparia are not true to name. The trouble all arises from the omission to check the coarser growing shoots in the manner described. When these plants assume autumnal tints and the nights become colder, they may be potted up for the decoration of the conservatory and the greenhouse. About ten days before their removal from the flower-beds, the roots should be cut through with a sharp spade at a distance of 3 inches from the main stem. It will be found, as a rule, that many new fibrous roots will be produced near to the stem, which will enable the plants to quickly overcome the check caused by removal. *F. James.*

Yellow Summer Reinette Apple.—Late flowering varieties of the Apple should form a considerable proportion of every collection in our most uncertain climate, and the above-named variety, flowering at the end of the month of May, almost invariably escapes injury from late frosts. *F. M.*

Forest Trees in Germany.—I have recently seen in Germany a wonderful collection of Pines, especially Sciadopitys verticillata, only inferior to the magnificent specimen at Mr. Bolitho's place at Trewidden, Cornwall. Shade and peat evidently suit this tree. The proprietor grows a large variety of Pines, some of his forests being some 5 miles in length, and he is always seeking for trees which will succeed in arid, sandy soil. He has found that the Banksian Pine, so far, has showed its superiority over P. silvestris and P. Strobus. It was interesting to see the great care and method adopted by the Germans in planting their forests. Quercus rubra is another of their favourite trees even in soil which we should not believe to be able to support it: but then water is also found at a depth of 10 feet. *B., Cork.*

Gladioli.—Herewith I send you a few spikes of some of my seedling Gladioli. The cream coloured one is a new seedling, and in common with a number of similar and equally good ones is pure in colour, and I think this purity will be maintained. As I have noted before in previous communications, wireworm has been a terrible scourge, but I have minimised its depredations to a great extent this season by ramming the beds after planting. Some I put a heavy stone roller over, but the Gladioli seem to like it, and this process has succeeded when both heavy doses of soot and vaporite both failed utterly. *W. C. Bull.* [Large spikes of well formed, brilliantly coloured flowers.—Ed.]

Apple Early White Transparent.—I am forwarding you a few fruits of the above-named Apple. They are picked from a young nursery espalier tree only planted last December. We have not grown this variety before, but were we planting a number of trees for early fruiting should decidedly put a good proportion of the variety in question. I do not know anything of its history, it is not mentioned in Hogg's *Fruit Manual*, though I find it catalogued by several of our leading nurserymen. Judging by appearance it has evidently some close relationship to Lord Suffield or Keswick Codling. I enclose a fruit of the former for comparison. *H. J. C., Grimston Gardens, Tadcaster.* [In shape very like Calville Blanche, and very fragrant and richly flavoured.—Ed.]

The Plum Crop.—After carefully reading the reports of the fruit crops, I notice a great scarcity of plums. I am sending a branch for your inspection that I left unthinned. I am pleased to state that we have a remarkable crop of these fruits. The garden consisting of 2½ acres of ground is all walled around, and the fruit crops this year are particularly good, there being an abundance of all small fruits. The soil here is loam on chalk, the situation high, being almost level with Box Hill. *Thos. Beeson, Headley Park Gardens, Epsom.* [The small spray sent was carrying about four dozen fruits, that hung in clusters. Mr. Beeson is to be congratulated, for most other growers have next to none.—Ed.]

Blackberries.—The note from Maidstone (p. 137) in reference to the promise of a Blackberry crop this season is interesting in so far that it applies to this one fruit which seems to be acceptable to all when ripe, and which is, in consequence of its wildness, everybody's fruit But the conditions under which Blackberries are habitually grown wild, by roadsides in crowded hedgerows, with roots starving from want of moisture at the fruiting season, too often cause the promise of a crop, judged by the blossom seen, to be followed by disappointment. The people who collect Blackberries so produced seldom have the fruit fully developed or ripened, hence the need of its culture on a large scale It is not at all difficult to obtain the plant in commerce, and some very fine selections of British Brambles exist which, under good culture, produce fine, richly-flavoured, juicy fruit. These well repay proper culture. There is the well-known, yet far too little grown Parsley-leaved Bramble, Rubus laciniatus, plants of which should find a place in every garden. Earliest of all, however, is the now famous and large-fruited Loganberry, so far America's finest production among the Rubus tribe. This seems to adapt itself to any soil, and also to ripen its annual growths, in any sunny position. I saw but recently plants of it growing in almost pure sand at Reigate in a small garden, where early in July it was fruiting finely. The grower lamented that he had not room to grow it largely, there being such demand for the berries. Veitch's Mahdi is the result of a similar cross to that which produced the Loganberry, but the fruits are broader and of a deep claret colour. But whilst there are others which may be equally good, these named suffice to show that if any area of good, deep, retentive soil, well exposed to the sun, be planted with these very fine fruiting Brambles, not only will frost troubles be escaped by them, but there is a market open for the fruit and remunerative prices awaiting them. *A. D.*

The late William Chester.—Many of the present and the old Chatsworth hands and other persons who came in direct contact with Mr. Chester will have read with regret of the death of this worthy gardener. Why not perpetuate the name of "William Chester" by making a special appeal inviting donations to a fund on behalf of the Royal Gardeners' Orphan Fund? Many of the Chatsworth hands are to-day subscribers to the R.G.O.F., but I venture to think that many would still be prepared to contribute on behalf of such a "memorial" fund, the sum collected to be paid in either as a "donation" or as might be decided later. Should there be anyone with greater influence than myself I am willing to co-operate and send my donation, but, failing another, I shall be glad to "act" in the interests of a fund for the purpose. Donations need not be large in every case, but the many should make a respectable sum which would be gladly received to strengthen the funds of the society in question. *Stephen Castle, West Lynn, Squires Lane, Finchley, London, N.*

Viola Virgin Queen.—I forward you a bunch of Viola Virgin Queen to show how well it stands drought, even on a light sandy soil. The habit is perfect. I find it a valuable variety for florists' work owing to the flowers possessing long stalks. The flowers are of the purest white, and it has been highly spoken of. *Arthur Young, Oxted Nursery, Oxted, Surrey.* [An excellent white variety of robust habit and with large fragrant flowers that are produced in abundance.—Ed.]

Sutton's Evergreen Dwarf Bean.—I sowed one row of this variety beside Canadian Wonder, and picked pods quite 10 days before the latter came into bearing. We have been picking during the past six weeks, and shall do so for some time. Our ground is rather heavy and gets very dry, and as the weather has not been favourable for growing Beans, I consider my rows have answered all expectations. It has also proved, with me, a good forcing variety. *J. A. Huntley, The Gardens, Oak Hall, Buckhurst Hill.*

Obituary.

Squibbs, Robert.—We regret to record the death, in his 83rd year, of this highly esteemed gardener, which took place at his residence, Albion Terrace, Sleaford, on Thursday the 9th inst. Mr. Squibbs was for many years head gardener to the Marquis of Bristol at Ickworth Park, and was held in high esteem by his lordship and the members of the family.

SOCIETIES.

ROYAL HORTICULTURAL.

Scientific Committee.

August 14.—*Present* Mr. G. Massee, F.L.S., V.M.H. (in the chair); Messrs. G. Nicholson, E. M. Holmes, J. Odell, C. Shea, C. H. Hooper, H. Gussöw, and F. J. Chittenden (hon. secretary). Visitor, Mrs E. Hancock.

Diseased Cinnum and Dracæna.—Mr. Gussöw reported that he had examined these shown at a recent meeting by Mr. Worsley, but had been unable to find on either any parasite to which the death of the plants could be attributed.

Reversion in Picotee.—Concerning the plant shown by Mr. Douglas at the last meeting, Mr. F. Williams, F.L.S., writes: "The stem sent to me bears a female flower only, and the styles are very much coiled, as is so frequently the case when only female flowers are produced From the clear and interesting history given with the plant, the result is not at all a matter of surprise. It is certainly a curious result. It is an attempt on the part of the seedling at atavistic reversion to simpler type—of a form of reversion so lucidly described by Mendel in his experiments on hybridisation, and to which I have drawn attention in reviews of Mendel's work in the *Journal of Botany*, and in an explanatory note in my *Prodromus Floræ Britannicæ*, part III. The whole energy of the plant was directed to modification—and a very marked one—of its nutritive organs at the expense of the development of its floral organs. . . . . The whole of its energy of growth was expended in the modification of the leaves. . . . Even when the flower is produced it is (in the specimen sent) an imperfect one. No doubt it was less coddled in its cultivation than other specimens, and so took the opportunity in a harder environment to revert to a simpler type I have before pointed out that Pinks resent coddling as much as they can; the natural habitat of all species of Dianthus is in exposed situations, slopes of hills facing the wind, edges of rocks, overhanging ledges, unprotected banks, and open sandy ground. Altogether the specimen has a much more wild appearance than its somewhat artificial origin suggests."

Smut in Carnation.—Mr. Massee reported that flowers of Carnation Miss Audrey Campbell with discoloured centres were "attacked by the fungus Ustilago violacea, and to the presence of this fungus the discolouration was due. The spores of the fungus are produced in the anthers In several of our wild plants belonging to the Pink family this disease occurs, and in those instances the mycelium is a perennial in the root. Hence it appears every year, and a plant once infected remains so for life."

Malformed inflorescences.—Mr. Odell showed some specimens of Trifolium repens virescent, similar to those shown at the last meeting by Mr Sutton He said that he found it much more frequently in temporary than in permanent pastures He also showed Plantago major with virescent flowers, and Scabiosa atropurpurea in which the central florets were displaced by long green bracts.

Damaged Cactus stems.—From Teignmouth came shoots of Phyllocactus showing brownish spots of somewhat irregular shape, and nearly a quarter of an inch in diameter In the centre of each was a dark spot looking like a puncture. These were no doubt caused by punctures from the spines on neighbouring shoots, and by the production of cork on the part of the plant in its efforts to heal the wound made by the spines.

Buds on inflorescence of Saxifrage.—Mr E. H. Jenkins of Hampton Hill, sent a specimen of Saxifraga Cotyledon received from Bavaria, in which a large number of small rosettes of leaves had been produced in the axils of bracts on the axis of the inflorescence. He said that the occurrence was very frequent this year with this species, and suggested that "by reason of the incessant rains experienced there the functions of the flowers were interrupted, or their power of forming seeds destroyed. Possibly the pollen had been washed away or injured, and no seeds were formed The flowering stems remaining green beyond their usual time directed their energies to the formation of these small rosettes."

Montbretias dying.—Plants of Montbretia with foliage dying and turning a dark brown colour came from Chingford The trouble seems common this year, and appears to be a physiological one rather than one due to any specific organism. The best plan to adopt in order to avoid its occurrence appears to be to move the plants at least every two years; plants left for a longer time very frequently succumb to the disease.

Bean anthracnose.—Specimens of Runner Beans were received from Plympton badly affected with Bean anthracnose caused by the fungus Colletotrichum undemuthianum. The disease is described, and treatment indicated in *Gardeners' Chronicle*, 23 (1898), p. 293, and *Journal Royal Horticultural Society*, xxvii. (1902), p. 809.

Melampyrum arvense.—Mr Chittenden showed specimens of the Purple Cow Wheat (Melampyrum arvense), a somewhat rare semi-parasitic cornfield weed in England, from an Essex locality, together with the seeds, which bear a remarkable resemblance to dark grains of wheat

Solanum Commersoni Mrs. Hancock gave an interesting account of the way in which she introduced this plant, which has recently been the cause of a considerable amount of discussion among growers of Potatos, particularly on the Continent, into her garden from Mons. Labergerie's garden at Verrières after the Brest conference. She first received it in January, 1904, and has succeeded in establishing it thoroughly well in her garden at Horeham Road, Sussex, and has since been able to distribute a considerable number of tubers to different parts of the country. She finds it will withstand a greater degree of cold than do the varieties of S. tuberosum. Her remarks were illustrated by a photograph of the plant growing, specimens of the plant in flower, and with immature fruits and tubers of a considerable size. She had cooked the tubers and found they possessed no bitter flavour.

EASTBOURNE HORTICULTURAL SOCIETY.

August 15.—The above society held its annual show in the grounds of Compton House, kindly lent by his Grace the Duke of Devonshire, K.G. The private gardens were also thrown open to the visitors, while her Grace gave permission for the famous Dexter cattle, with which so many prizes have been won, to be viewed.

The exhibition was held in four large tents, which in some cases were much crowded, so great was the competition in some of the classes.

The attendance of the general public was numerous.

Plants.—Some good groups of plants were seen, the 1st prize for these being secured by Mr. G. T. Scott, Upperton and Ceylon Nurseries; 2nd, Mr. I Duke Dinner table decorations formed a strong feature The premier award in the professionals and nurserymen's classes was well won by Mr. A B Wadds (gr. to Sir Weetman Pearson, Bart., Paddockhurst, Worth), he having a splendid table, decorated largely with Odontoglossum crispum The 1st prize in the ladies' class was won by Mrs. Raffey Messrs. Clark and Jenner staged respectively the best sprays and buttonholes.

In the Rose classes chief honours fell to Messrs. Durant-Young, with Mr. Eversfield 2nd

In the open smaller class for 24 blooms Messrs. Young, Woollard, and Eversfield won in the order named.

Dahlias of high quality were staged Messrs. Cheal and Sons, Crawley, were placed 1st for Cactus, for single varieties, and for pompon Dahlias

The best 18 bunches of hardy perennials were shown by Mr. A Charlton, and he was easily first, having splendid material. Mr. G H. Simmons (gr. to H. G. White, Esq.), won the 2nd prize.

Messrs. Peters and Duke won in the classes for Gladioli in the order named.

Stove and greenhouse plants are not so well staged now as they were years ago, but good groups of Begonias were shown by Mr. W. F. Thomas, Wannock Flint Garden, who secured the 1st place, and by Mr W Unsted who was 2nd. Mr. Godden showed the best Fuchsias, Mr. I Duke the best specimen plant in bloom, and Mr Lyddiard the best foliage plant Messrs. A Kemp and G Grigg had the best decorative plants, and Mr. Lyddiard the best exotic Ferns.

The premier group of Ferns were those shown by Messrs. Penrose Bros., Hurstmonceaux.

Mr. I Duke was to the fore in the class for foliage plants.

Fruit of splendid quality was seen in all the classes. Plums were not shown largely, but no

falling off in their quality was noticeable. No fewer than six collections of fruits were seen. Mr. J. GOKE, Albion Vineyard, Polegate, won with an assortment including splendid quality Grapes, Peaches, Nectarines, and Melons. Mr. G. GRIGG (gr. to the EARL OF ASHBURNHAM), was a close 2nd. A good Pineapple was seen in the 2nd prize display. 3rd, Mr. H. Poulton (gr. to C. T. CAYLER, Esq., Tunbridge Wells).

In the Grape classes Mr. J. GOKE led easily for black kinds, while Mr. W. WELLER had grand bunches of Muscat of Alexandria in that for white fruit. The class for any other variety of Grape saw Messrs. GRIGG, POULTON, and GOKE in the order named. Mr. F. THOMAS had the best scarlet-fleshed Melon in a strong competition, and Mr. WEST the best green fleshed. Mr. J. Bettles (gr. to CECIL CHANDLESS, Esq., Sherrington Manor) was an easy 1st winner for Figs, a class usually well contested at this show, Mr. T. WEST being 2nd. Mr. J. GOKE showed the finest Nectarines, and Mr. G. GRIGG the best Peaches. The last-named exhibitor was also first for dessert Pears. Mr. GRIGG showed first-class Apples, and his were also the best dessert Apples. In a class for a collection of Apples, Mr. THOMAS was easily 1st, Messrs. GOLDSMITH and HUNT taking 2nd and 3rd prizes respectively.

Vegetables of good quality were seen. In the class for a collection, Mr. A. B. WADDS, Paddockhurst, was an easy 1st prize winner, and he was followed by Mr. KEMP, Mr. PUTLAND being 3rd.

Some splendid non-competitive exhibits of plants and flowers were seen. Groups were staged by Mr. MAY, Compton House Garden; Messrs. DURANT-YOUNG, Eastbourne; Messrs. CHEAL and SONS, Crawley; Messrs. CHARLTON and SONS, Tunbridge Wells; Mr. WILL TAYLOR, Hampton; Messrs. WALLACE and Co., Colchester; Messrs. BARR and SON, Covent Garden, and Messrs. HICKS and BLOOMFIELD, Reading.

ANSWERS TO CORRESPONDENTS.

ASPARAGUS MULCH: *A. B.* The reason Asparagus beds are generally mulched in the autumn, after the plants have matured their growth and the latter have been cut down and removed to the fire heap, is to prevent the roots and "crowns" from sustaining injury from the effects of severe frosts during the interval elapsing between November and March. The soil is raked off the individual beds into the alleys prior to laying on the three inches thick surface dressing of manure. Early in March the soil is shovelled up and scattered over the beds and the surface raked evenly preparatory to the "grass" coming up uninterruptedly through the six inches or so covering of manure and soil; the autumn and winter rains meanwhile will wash the substance of the mulch down to the roots, to be assimilated by the latter in due time. It would not be advisable or practicable to mulch the beds in the manner indicated by you immediately after the crop has been taken, say the middle of June, as the late young growths which had not then pushed through the soil would be likely to get injured in the process, although an ordinary surface-dressing of manure laid on the beds at that time without disturbing the surface soil would certainly have a beneficial effect. The fact of growers residing in seaside districts mulching their Asparagus beds in the autumn, after the September gales have washed the Seaweed ashore, only affords in this case an additional reason for doing the work at this time of the year. The mulching of Asparagus beds in the autumn, as indicated above, is sound in practice and in theory. The conclusions you arrived at in the last two lines of your note are erroneous. *H. W.*

BEECH COCCUS: *W. E. N.* The white floculent mass is composed of insects that are destructive to the trees, and they should be eradicated. You will notice that they only attack the main stem and the larger branches. The best remedy is to scrub the bark and the crevices with petroleum emulsion or with caustic alkali wash. Paraffin emulsion is best prepared by mixing a solution of soft soap in boiling water with an equal quantity of paraffin, thoroughly mixing the two together, and then adding, when required for use, 20 times the bulk of water, churning and mixing as before. Caustic alkali wash is made by dissolving 1 lb. crude caustic soda in water, then adding 1 lb. crude potash or pearl ash, also dissolved in water, ¾ lb. soft soap, and water sufficient to make up to 10 gallons of the mixture. This wash being of a very caustic nature, gloves should be worn by the operator, and the mixture must not be allowed to reach the foliage.

BEGONIAS: *Anxious.* From what you say we conjecture your plants are attacked with the Begonia mite. If so, steeping the plants in tobacco water will destroy the mites, but without seeing the plants it is not possible to give an accurate opinion.

BOOKS: *R. R.* Bentham's *Handbook of the British Flora*, which may be had from our publishing office price 9s. 4d., free by post.

CARNATIONS: *H. B.* The cuttings have rotted from having been planted too deeply and kept too wet. There is neither fungus nor eelworm.

CHRYSANTHEMUM LEAVES CURLING: *B. W.* The diseased condition is due to a rust fungus, Puccinia Hieracii. This disease was figured and described in our issue for October 8, 1898, p. 269. Spray the plants when they are making their growth with potassium sulphide, using ½ ounce of the potassium salt to one gallon of water. You must be careful not to propagate from diseased plants; indeed they should be burned at the end of the season, and a new stock obtained from healthy plants.

CORRECTION: P. 135, col. at end of first paragraph, for "month" read year. *F. M.*

ETHER FORCING: *E. H.* There is no book in English that we know of. The matter has been treated of in our back numbers. Apply to the secretary of the station you mention.

EUCALYPTUS: *F. K.* The shoot is swarming with aphis. Spray the plants with some insecticide such as tobacco water, quassia extract, or soft soap and water with a very small quantity of paraffin added.

FLOWER SHOW JUDGING: *J. J. G.* If the exhibitor publicly announces that he sells his flowers, &c., and this as part of his business from which he derives his livelihood, he cannot be ranked as an amateur. However, the committee being appealed to should know all the facts of the case, and we advise you to accept their decision.—*J. S.* The schedule is worded loosely. If it means 12 distinct genera then you are right in your assumption, but if you have more than one variety of Pentstemon, they might make, with others shown, a total of more than 12 varieties, which number was not to be exceeded. This would, of course, apply to any other vase or vases in the exhibit; for instance, if Roses were shown they must be all of one kind.

FRENCH GARDENING PAPER: *J. K. Le Jardin*, 84 Rue de Grenelle, Paris. If you apply to the Editor of that paper, he will no doubt answer your queries.

GRAPES DISEASED: *H. O. and Amateur.* The berries are affected with the "spot" disease, so often described in these columns. Cut out and burn any of the berries that are diseased and spray the remaining ones with liver of sulphur one ounce to two gallons of water, taking care not to wet the paint.

GUNNERSBURY PARK GARDENS: We understand that all the glass houses in these noted gardens (see p. 121) were erected by Mr. James Gray, Danvers Street, Chelsea, S.W.

LILIUM AURATUM FAILING: *A. B.* The plants are attacked by the Lily disease, caused by a fungus—Botrytis sp. Bulb mites are also present and some of the scales are rotting. We advise you to burn all the affected plants, and to spray the healthy ones with a weak solution of permanganate of potash. Do not plant Liliums on the same plot of ground for some seasons.

NAMES OF FRUITS: *W. G. S.* 1, Emperor Alexander; 2, Adam's Pearmain; 3 and 4, Send again later; 5, Beauty of Hants; 6, Gascoigne's Scarlet.—*W. H. B.* 1, Quarrenden; 2, Not recognised; 3, William's Favourite; 4, Juneating; 5, Duchess of Oldenburgh; 6, Irish Peach.—*Interested, Swanley.* Sugar Loaf.

NAMES OF PLANTS: *A. D. G.* 1, Cypripedium Lowii; 2, Cypripedium Stonei.—*Lewis Hawkins.* 1, An Acacia; 2, A species of Solanum, no flowers sent; 3, Leycesteria formosa; 4, Albizzia lophantha; 5, Polygonum orientale.—*R. R.* 1, Gnaphalium margaritaceum; 2, Malva moschata alba; 3, Sedum spurium; 4, Inula Helenium; 5, Omphalodes verna; 6, Achillea Millefolium, pink var.; 7, Spiræa filipendula; 8, Stachys lanata.—*H. H., Sandhurst.* Oncidium flexuosum. The black fly in Chrysanthemums can be kept down by occasional spraying with a safe insecticide, or dusting with one of the preparations used in the form of powder.—*T. H.* 1, Prunus Pissardi; 2, Cornus mas variegatus; 3, a Cupressus, we cannot tell which from the specimen sent; 4, Euonymus radicans, variegated form; 5, Philadelphus; 6, Send when in flower.—*C. B. & Co.* A variety of the common Honeysuckle, Lonicera Periclymenum.—*Fairmile.* Ophiopogon Jaburan; Arabis next week.

PARTNERSHIP: *A. C. R. W.* We certainly do not advise you to commence business before you have had some experience. As you are without any we advise your entering some nursery or gardens for at least a time, and, if possible, adding to your capital, which is very inadequate. A list of nurseries to let is to be found in our advertising columns. Messrs. Protheroe & Morris publish a monthly register of places to be let or sold.

PLANTS UNHEALTHY: *E. H. and W. B.* We have submitted the specimens to our expert, who states the injury is not caused by either fungi or insects. The peculiar appearance must be due to faulty treatment, to be determined only on the spot.

SPANISH IRISES, ETC.; *Quality.* The following varieties, with their colours, are among the best for your purpose:—Cantab, blue; Snowball, white; Princess Ida, white, primrose, and orange; Lemon Queen, canary yellow; California, deep golden; Donna Maria, azure and white. The Fuchsias should include Avalanche, Rose of Castille, Mrs. Marshall, Lord Beaconsfield, Scarcity and the species fulgens, which is very suitable for culture in bush.

TOMATOS NOT RIPENING: *G. H.* The parti-coloured appearance is not due to fungoid disease, but seems to result from a thickening of the placenta and base of the fruit which does not ripen properly. Give the plants some manure that is rich in potash. The Chrysanthemum shoots are curled similarly to those sent by *B. W.*, but yours are not affected by the rust disease; the injury in your case is caused by insect mites and green fly. Dip the shoots in tobacco water.

SHROPSHIRE HORTICULTURAL.

Exhibition at Shrewsbury.

The thirty-second annual show of this remarkably successful society was held on Wednesday and Thursday last in the beautiful grounds belonging to the society itself, and known as "The Quarry." Successful though previous Shrewsbury shows have been, this one was at least equal to any of its predecessors. In some respects it may have been even better than others, and, taken as a display, it certainly was larger, for there were one hundred entries at least in excess of those obtained in any previous year. More tents were, therefore, requisitioned, and the aggregate area covered by these was equal to 1,500 square feet in excess of last year. There were more than 400 bunches of Grapes. The receipts of all kinds at the show last year amounted to the extraordinary sum of £5,238 6s. 11d., and when our representative left the show on Wednesday evening there were indications that even this record would be excelled. The weather on the opening day was brilliantly fine, and the number of visitors correspondingly large. The amount of money offered in prizes was over £1,100, besides valuable cups, medals, and other special prizes, and it is worth while to point out that all this was awarded for skilful cultivation alone. New plants were invited in Class L, and Certificates were awarded to the best of those shown, but no money prizes were awarded to these. We, as gardeners, have every reason to be glad that the skilful cultivation of plants, fruits, and flowers is so liberally encouraged as it is at Shrewsbury, and there can be little doubt but that this and similar exhibitions exercise a good and powerful influence on British horticulture.

At the same time, when we consider the important position that the Shropshire society has obtained in the country by reason of its great shows, there appears to be some reason for suggesting that at future exhibitions a class should be provided for new plants, and liberal prizes offered for them. The society is looking for some means of introducing a new feature into its yearly displays, and it is rich enough to offer such substantial prizes for new plants as would be pretty certain to meet with a satisfactory response from exhibitors. The effect of bringing new plants to Shrewsbury would certainly be to increase the reputation of the society, which is already entitled to credit for having provided a statue to Charles Darwin in his native town, and for making many and liberal charitable gifts.

But taking the show as it is, all who have seen it will acknowledge that a better exhibition of horticultural products could hardly be made, and it should be, and it is, a very great incentive to visitors whose enthusiasm for good gardening may need encouragement. The Grapes from Lord Hastings and others, the choice fruits from the Earl of Harrington, and G. Farquhar, Esq., the vegetables from Lord Aldenham and the Duke of Portland, and the specimen plants from Messrs. Cypher & Sons, and J. Sutton Timmis, Esq., were beyond praise. The local exhibits of cut flowers and vegetables, also of wild flowers, were satisfactory as usual. How each competitor fared in the more important of the open competitions may be seen below, and it only remains for us to remark on the energy and tactfulness of the two honorary secretaries, Messrs. Admitt and Naunton, to whom we, and our readers, are indebted for the courteous help they are always ready to afford.

Fruit.

Tables Laid as for Dessert.

Of all the classes arranged for exhibits of fruit, none appears to be more popular with visitors to the show than that for tables laid out as for dessert, with choice fruits and suitable floral decorations. Though there are usually not many competitors in this class, the exhibits make a considerable display, for each table measures 10 feet by 4 feet 6 inches. The tables are covered with white cloths, and may be decorated with plants in pots not exceeding 5 inches in diameter, cut flowers (other than Orchids), and ornamental foliage. No exhibitor may show more than fifteen dishes of fruits, and the kinds must be selected from a list published in the schedule. Every exhibitor provides his own epergnes, vases, &c., required for the cut flowers, also the necessary receptacles for the plants and for the fruits. At this show there were four tables, and that awarded the 1st prize was the exhibit of the Earl of Harrington, Elvaston Castle, Derby (gr. Mr. J. H. Goodacre). He had Muscat of Alexandria and Madresfield Court Grapes, Royal George, and Bellegarde Peaches, Pineapple, and Humboldt Nectarines, Marguerite Marillat, and Souvenir du Congrès Pears, brown Turkey Figs, Ribston Pippin and Cox's Orange Pippin Apples, and two Melons. The points awarded for each dish were as follow:—

	Possible No. of Points	Points Awarded.
Apples (1)	7	7
Apples (2)	7	7
Figs	7	5½
Grapes, Black (1)	—	7½
Grapes, Black (2)	—	8½
Grapes, White (1)	—	9½
Grapes, White (2)	—	8
Melon (1)	8	8
Melon (2)	8	6½
Nectarines (1)	8	7½
Nectarines (2)	8	8
Peaches (1)	8	7½
Peaches (2)	8	6½
Pears (1)	7	6½
Pears (2)	7	5
Beauty of flower and foliage	8	7
Harmonious blending of colour	10	9
General arrangement for effect	10	9
Total		132½

The decorations in this exhibit were flowers of Schizanthus retusus and Francoa ramosa, arranged in glasses with suitable relief. The 2nd prize was awarded to G. Farquhar, Esq., Ledbury (gr. Mr. G. Mullins), whose exhibit was awarded 119 points. This exhibitor obtained full points for one dish of Apples. 3rd, Joseph Drakes, Esq., Market Rasen (gr. Mr. T. Cooke), who obtained 115½ points. The Hon. E. L. Wood, Temple Newsam (gr. Mr. R. Dawes), who obtained the 4th prize, had very pretty decorations of Montbretias and Gypsophila paniculata fl. pl., Francoa, &c.

Collections of Fruits.

There were three classes for collections of fruit, one calling for sixteen dishes, another for twelve dishes, and the third for nine dishes. As Pineapples are now only cultivated in few gardens, they were excluded from the competition in each case. All exhibits were decorated, but special prizes being awarded for the decorations, they were not considered during the judging of the collections of fruits.

Collection of Sixteen Dishes of Fruit in Sixteen Varieties, and not fewer than Twelve kinds.—Liberal prizes, which amounted to £52, were offered in this class. There were three collections staged, and the 1st prize was won by G. Farquhar, Esq., Ledbury (gr. Mr. G. Mullins). He had excellent Black Hamburgh, Black Alicante, Muscat of Alexandria, and Canon Hall Muscat Grapes, the last-named variety being least good; marvellous fruits of Gascoyne's scarlet Seedling Apple, good Marguerite Marillat Pears, Pineapple, and Elruge Nectarines, Bellegarde Peaches, Moor Park Apricots, Kirke's Plums, Duke of Sutherland Gooseberries, Brown Turkey Figs, Bigarreau Napoleon Cherries, and Sutton's A 1. and Countess Melons. The Earl of Harrington, Elvaston Castle (gr. Mr. J. H. Goodacre), who has frequently won the 1st prize in this class, was on this occasion placed 2nd. His Grapes were of the varieties, Madresfield Court, Chasselas Napoleon, Black Hamburgh, and Muscat of Alexandria. He had good Peaches, rather small Nectarines, small Turkey Apricots, and among other dishes one of Royal Sovereign Strawberry; 3rd, the Hon. E. L. Wood, Temple Newsam (gr. Mr. R. Dawes). The prizes for decorations in this class were awarded as follow: 1st, G. Farquhar; 2nd, the Earl of Harrington; and 3rd, the Hon. E. L. Wood.

Collection of Twelve Dishes.—There were four exhibits in this class, and the 1st prize was won by J. Drakes, Esq., Market Rasen (gr. Mr. T. Cooke). His Muscat of Alexandria Grapes were large bunches, but they were far from being well coloured; Madresfield Court was extra good in size and colour, but the bunches were scarcely so shapely as usual with this choice Grape. The other varieties shown were Foster's Seedling and Gros Maroc. Peasgood's Nonsuch Apples were capital, as were Barrington and Diamond Peaches, Spencer Nectarine, Triomphe de Vienne Pears, Brown Turkey Figs, Countess Melon, and a dish of yellow Plums. The Earl of Sandwich, Hinchingbrooke (gr. Mr. Barson) was awarded the 2nd prize, and Lord Bagot, Rugeley, Staffs. (gr. Mr. T. Bannerman) was 3rd. The prizes for decorations in this class were not awarded in the same order, for the 1st prize was obtained by G. Bates, Esq., Whitfield (gr. Mr R. Grindrod), who won the 4th prize for the fruit. The winner of the 1st prize for fruit, however, won the 2nd prize for decoration.

Collection of Nine Dishes.—The best of four collections of nine dishes came from C. F. K. Mainwaring, Esq., Otley (gr. Mr. C. Wilkins), and the 2nd and 3rd prizes were awarded to Mrs. Swann, Halston Hall (gr. Mr. C. Roberts), and the Rev. T. M. Bulkeley Owen, Tedsmore Hall (gr. Mr. J. Langley). The fruit shown in the larger collections was superior.

Separate Kinds of Fruit.

Peaches and Nectarines.—There were as many as thirteen dishes of Peaches in the class for a single dish, and the cultivation they exhibited was of high merit, but not unusually so. One of the specimens in the 1st prize dish of Prince of Wales was of an astounding size. This exhibit was from Sir Geo. Meyrick, Bart. The variety Royal George, from the Earl of Lathom, Ormskirk (gr. Mr. B. Ashton), was placed 2nd, and was remarkable for its high colour. Dymond, from J. Fleming, Esq., was placed 3rd. There were nine single dishes of Nectarines, and J. Fleming, Esq., had the best in "Pineapple"; 2nd, T. F. Kynnersley, Esq., Leighton Hall (gr. Mr. W. Phillips), with the same variety, Lord Bagot's "Lord Napier" being 3rd.

Apricots appeared hardly as good as we have seen them before at Shrewsbury, but there were ten dishes of six fruits each shown in the class for a single dish.

Melons were judged by flavour, and the best green-fleshed variety out of twenty-three exhibits was Royal Jubilee, shown by A. Gibbs, Esq., Bristol (gr. Mr. T. Wilkinson). There were twenty-four scarlet-fleshed Melons, and the best was one shown by Capt. Dickin, Loppington House (gr. Mr. G. Gilbert), which was unnamed. Of twenty white-fleshed fruits, the best was shown by T. F. Kynnersley, Esq.

Plums.—The present is not a good Plum year, and exhibits were fewer than usual. J. Drakes, Esq., had the best dish of twelve Gages, and the Rev. T. M. Bulkeley-Owen the best dish of yellow Plums in Oullin's Gage. The best purple or red Plums were shown by the Earl of Harrington.

Cherries were shown splendidly, and in nine instances. The Morellos from Captain Dickin were as large as Plums.

Hardy fruits.—In a class for six dishes of hardy fruits (limited to cultivators in Salop) the 1st prize was won by Mrs. E. Alderson, Frankton (gr. Mr. G. Davies), whose Cherries and Gooseberries were the best "dishes." There were several smaller classes for fruits also limited to growers in Shropshire.

CHAMPION GRAPES.

This is the fifth year in which a Silver Champion Cup of the value of 50 guineas has been offered for the best exhibit of 12 bunches of Grapes, in four or more distinct varieties, but including not more than four bunches of any particular variety. The cup has to be won three times by the same competitor before it can become his property, and it may be remembered that last year, when Mr. Shingler, gr. at Melton Constable, won it for the third time he was unable to claim the cup because, on the two former occasions, the exhibitor was the late Lord Hastings, and last year the present Lord Hastings. The cup has only been won on one occasion by any other exhibitor, the occasion having been in 1903, when the Earl of Harrington gained the 1st prize in this class. The cup is accompanied by a sum of £20 in cash, and the remaining prizes in the class are £16, £12, £7 10s., £5, and £4 respectively. The judges are instructed to regard superior cultivation and "finish" as points of the greatest importance. Thus, a maximum of 11 points is allowed per bunch for the variety Muscat of Alexandria, whilst 10 may be given to all other Muscats (black or white) and to Black Hamburgh, but only nine points to any other variety. The schedule requires that each exhibit must be decorated with plants in pots, or cut flowers, &c., but extra prizes are awarded for the decorations, and they are not considered in the least when judging the Grapes. There were eight exhibits on the occasion under notice, and the 1st prize, including the Champion Cup, was awarded to Lord HASTINGS, of Melton Constable, Norfolk (gr. Mr. Shingler), the winner last year. There were three more exhibits in this class than there have been previously. Mr. Shingler has, therefore, the greater honour in retaining the premier position. His two bunches of Mrs. Pince were probably the best of this variety that have been staged at Shrewsbury. The points awarded each variety were as follow:—

	Maximum No. of Points.	Points Awarded.
Mrs. Pince (1)	10	8½
Muscat of Alexandria (2) ...	11	8½
Mrs. Pince (3)	10	9
,, ,, (4)	10	9½
Muscat of Alexandria (5) ...	11	8
Mrs. Pince (6)	10	9
Black Hamburgh (7) ...	10	8
Muscat of Alexandria (8) ...	11	10
Alnwick Seedling (9) ...	9	8½
,, ,, (10) ...	9	9
Madresfield Court (11) ...	10	7½
Gros Maroc (12)	9	8
Totals	120	103½

The 2nd prize exhibit was one from G. FARQUHAR, Esq., Ledbury (gr. Mr. G. Mullins), and this collection was awarded 102 points, or only one and a half fewer than Mr. SHINGLER gained. Mr. MULLINS' varieties were as follow:—

	Maximum No. of Points.	Points Awarded.
Gros Maroc (1)	9	8½
Muscat of Alexandria (2) ...	11	9
Black Hamburgh (3) ...	10	9½
Muscat of Alexandria (4) ...	11	9
Black Alicante (5)	9	8
Gros Maroc (6)	9	8½
Black Hamburgh (7) ...	10	7½
Gros Maroc (8)	9	8½
Muscat of Alexandria (9) ...	11	9
Black Hamburgh (10) ...	10	8
Muscat of Alexandria (11) ...	11	9
Black Hamburgh (12) ...	10	7½
Totals	120	102

It will be seen that in four cases the bunches shown were allowed the maximum number of points, save half a point. No. 3 bunch (Black Hamburgh) was a marvellously fine bunch, being extremely large, heavily shouldered, and splendidly coloured. The 3rd prize was won by J. W. FLEMING, Esq., Romsey, Hants. (gr. Mr. W. Mitchell), who was awarded 101½ points, and the 4th by the Earl of HARRINGTON, who had 99 points. The other exhibitors were J. DRAKES, Esq., Market Rasen (gr. Mr. T. Cooke), 83 points; J. T. CRAWFORD, Esq., Melton Mowbray (gr. Mr. W. Clanacham), 74 points; A. GIBBS, Esq., Flax Bourton, Bristol (gr. Mr. T. Wilkinson), 92½ points; and the Hon. E. L. WOOD, Temple Newsam (gr. Mr. R. Dawes), 73½ points. The 4th, 5th and 6th prizes were awarded according to the number of points gained by the exhibitors.

The 1st prize for the decorations was awarded to J. W. FLEMING, Esq., and the 2nd to G. FARQUHAR, Esq., the Earl of HARRINGTON gaining the 3rd prize.

OTHER GRAPE CLASSES.

The Grapes in the champion class, and in the collections of fruit, by no means constituted all the Grapes shown, for there were special Grape classes for most of the popular varieties.

Four bunches, two black and two white.—Out of five competitors the most successful was W. MARSH, Esq., Bath (gr. Mr. W. Taylor). He had Madresfield Court and Muscat of Alexandria, the first-named variety being remarkable for good finish, and the Muscats were very heavy bunches of moderately good finish. 2nd, Lord HARLECH, Brogyntyn (gr. Mr. T. Lambert), who showed the same varieties. 3rd, C. F. K. MAINWARING, Esq., Oteley (gr. Mr. C. Wilkins).

The following classes were for two bunches

Black Hamburgh.—There were 18 bunches shown in this class, and the best were from G. FARQUHAR, Esq., Ledbury (gr. Mr. G. Mullins), who had very good bunches of excellently coloured, fresh-looking, plump berries; 2nd, A. GIBBS, Esq., Flax Bourton, Bristol (gr. Mr. T. Wilkinson); 3rd, Lord HASTINGS, Melton Constable. The best single bunch was shown by Lord HASTINGS, among nine bunches.

Any variety of Black (Muscat) Grape.—W. MARSH, Esq., won the 1st prize in this class with the variety Madresfield Court; Mrs. Pince's Black Muscat shown by Sir GEO. MEYRICK, Bart., BODORGAN (gr. Mr. W. Pilgrim), was placed 2nd, and Muscat Hamburgh, from the Earl of HARRINGTON, 3rd.

Madresfield Court.—Out of 18 bunches exhibited in this class the best pair was shown by Lord HARLECH, and this exhibitor was followed by Col. TWEMLOW, Peakwood (gr. Mr. L. Barlow), and J. W. FLEMING, Esq., Romsey, Hants (gr. Mr. W. Mitchell).

Black Alicante.—There were seven exhibits, and the best was from W. MARSH, Esq., but two very fine bunches were shown by Sir D. DUCKWORTH KING, Bart., Countess Weir, Devon (gr. Mr. S. J. Walker); 3rd Lord TREVOR, Brynkinalt.

Any other Black variety.—Two excellent bunches of Gros Maroc of extra-sized berries shown by W. MARSH, Esq., were placed 1st, and equally good bunches of the ink-black Barbarossa from Sir GEO. MEYRICK, Bart., 2nd. There were nine exhibitors in this class, and the 3rd prize was awarded to two moderate bunches of Gros Maroc from J. W. FLEMING, Esq.

White Muscats.—There were 16 bunches of this variety shown in this particular class, the best being from the Earl of HARRINGTON, excellent in quality and finish, but only of moderate weight. The 2nd prize was awarded to two heavy bunches, imperfectly finished, from W. MARSH, Esq., and Major HIBBERT, Rugby (gr. Mr. W. Camm), obtained the 3rd prize. The Earl of HARRINGTON had also the 1st prize for the best single bunch.

Any other white variety.—W. HOWELL DAVIES, Esq., Stoke Bishop (gr. Mr. J. T. Curtis), was awarded the 1st prize for two splendidly-coloured bunches of Buckland Sweetwater. The same variety from H. A. ATTENBOROUGH, Esq., Daventry (gr. Mr. Child), was awarded the 2nd prize, and the same from the Earl of LATHOM 3rd prize.

There were seven other classes, in which competition was limited to cultivators residing in the county of Salop. First prizes in this section were secured by the Rev. T. M. BULKELLY-OWEN, Tedsmore Hall (gr. Mr. J. Langley), Lord HARLECH, Lord TREVOR, Brynkinalt (gr. Mr. W. Dawes), Capt. HEYWOOD LONSDALE, Shavington Hall (gr. Mr. J. Mills), E. P. THOMPSON, Esq., Whitchurch (gr. Mr. W. A. Webster), Major R. A. NEWILL, Admaston (gr. Mr. W. Ashwood).

GROUPS OF PLANTS.

We have never seen more effective groups of miscellaneous plants than some of those exhibited at Shrewsbury in recent years. Each exhibit being arranged on a space of 300 square feet, in a large marquee, where all the groups shown are placed in the centre in two rows, back to back, the effect on entering is of the most attractive description. On either side the immense display looks like a great tropical garden, in which the plants are arranged in as careful a manner as those in the best style of English mixed flower bedding. One of the two classes is for a group of miscellaneous plants in and out of bloom, and the other is for a group of ornamental foliage plants, Palms, Ferns, &c., excluding flowering plants. In the former class there were five exhibits, and the 1st prize was awarded to Messrs. CYPHER & SONS, Cheltenham, who have secured the premier place in so many previous competitions of this nature. The chief point worthy of note in respect to this year's groups was the absence of the cork bridge and arch arrangements that were commenced by Messrs. CYPHER, and afterwards copied by so many others that they at last became less attractive owing to their repetition. Not only have Messrs. CYPHER reverted, for a time at least, to a more simple and, we think, more natural style of arrangement, but every other exhibitor has done the same. Messrs. CYPHER'S group was, to use a paradox, like a well-regulated jungle, in which form and colour of leaf, as well as flower, were given careful consideration. It was furnished with a good background of Palms, Codiæums, Ixoras, &c., and at the front corners were pyramidal groups of plants, with smaller ones linking up these with one of rather less importance in the centre, the spaces beneath being glades filled with the choicest plants, all of which were placed in such positions that each specimen was effective. We cannot enumerate the varieties of plants used, but may remark that Ixoras, Clerodendron fallax, Odontoglossum crispum, Oncidiums, Cattleyas, and Lilium speciosum album were the most prominent of the flowering species. The 2nd prize was won by G. H. KENRICK, Esq., Edgbaston, Birmingham (gr., Mr. J. V. MacDonald), and the third by Mr. W. VAUSE, Leamington.

The best exhibit in the non-flowering group was shown by the LEAMINGTON NURSERYMEN AND FLORISTS, LTD., Leamington, and was one which called for the highest praise. The chief feature of the arrangement was in the free use made of large Codiæums, which were placed over almost the whole area at short distances, forming "dot plants," around which other plants were arranged. There were two magnificent specimens of Dracæna Victoria, and many other choice species were intermixed in the general arrangement. Messrs. CYPHER & SONS obtained the 2nd prize in this class, and J. W. LEAVERS, Esq., The Park, Nottingham, the 3rd prize.

In a local class for a group of miscellaneous plants covering 100 square feet, Mrs. SWANN, Halston Hall (gr. Mr. C. Roberts), was placed first, with a dainty exhibit.

SPECIMEN PLANTS.

Thirty Stove and Greenhouse Plants.—These plants were shown in pots not exceeding 10 inches in diameter. The 1st prize was won by T. SUTTON TIMMIS, Esq., Cleveley, Allerton, Liverpool (gr. Mr. B. Cromwell), who won the same prize last year, and who contributes our weekly calendar on the cultivation of "Plants under Glass." The plants on this occasion were of similar species to those exhibited on the previous occasion, and displayed the same high cultivation. The most remarkable specimens were those of Ixora Duffii and Codiæum Chelsoni, both of which appeared to be quite too large for a 10-inch pot, yet they were in perfect health and condition. The specimen of Ixora, which had 27 immense trusses of bloom, was specially awarded a cultural certificate. Messrs. J. CYPHER & SONS were awarded the 2nd prize, and Mr. W. VAUSE, Leamington, the 3rd prize.

Twelve Plants.—A smaller class for twelve plants, also limited to 10-inch pots, was won by Sir A. MUNTZ, Bart., M.P., Dunsmore, Rugby (gr. Mr. H. Blakenay); 2nd, Mrs. SWANN, Halston Hall, Oswestry (gr. Mr. C. Roberts).

Fifteen Stove and Greenhouse Plants.—This class, affording nothing novel in the species employed, was well filled, and the specimens shown by Messrs. CYPHER & SONS were of the best. They had Bougainvillea Cypheri, Allamanda nobilis intermedia, S. profusa, Ixora regina, Codiæum Mortefontainense, Ixora Duffii, Chronia ixifera, Erica Aitoinona superba, Ixora Fraseri, Kentia Belmoreana, K. Fosteriana, &c. The 2nd prize was won by Mr. W. VAUSE, Leamington.

The Rt. Hon. Lord Harlech, Brogyntyn (gr. Mr. T. Lambert), took the 1st prize for six stove and greenhouse plants confined to exhibitors in the county of Salop.

Tuberous-rooted Begonias were unusually good, and the exhibit from Messrs. Blackmore and Langdon, Bath, were quite up to the "Temple" standard: particularly good were the varieties Ellen Harper, Mrs. Cockrane, Nobilis, Mrs. W. L. Ainslie, and several unnamed seedlings; 2nd, Messrs. T. S. Ware, Feltham; 3rd, Mr. Fred Davis, Pershore.

Messrs. Blackmore & Langdon were also awarded the 1st prize for six Begonias, three double and three single flowered.

T. Sutton Timmis, Esq., Allerton, Liverpool (gr. Mr. B. Cromwell), staged the best group of six Dracæuas and the best six Caladiums.

The best exhibit of four exotic Ferns was from Mrs. J. H. Slaney, Wellington, and G. Burr, Esq., Oaklands, gained the 2nd position.

Four beautifully-trained pyramid Coleus gained for Col. W. Gordon, Patchett, Shrewsbury (gr. Mr. J. Swain), the premier award; 2nd, John Baker, Esq., Shrewsbury (gr. Mr. H. Worrall).

Mrs. Swann, Halston, and T. F. Kynnersley, Esq., were placed in the order named in a class for six stove and greenhouse plants. The 1st prize included six well-flowered plants of Allamanda nobilis, Bougainvillea Cypheri, and Statice profusa.

The best half-dozen ornamental foliage plants came from T. Sutton Timmis, Esq., Allerton, Liverpool (gr. Mr. B. Cromwell), whose plants were models of good culture. He staged Codiæum aureum marmoratum, C. Queen Victoria, C. Countess, C. Mortefontainense, and two Palms; 2nd, Messrs. J. Cypher & Sons, with three Codiæums and three Palms; 3rd, Mr. W. Vause.

Cut Flowers.

Collection of Hardy Perennials, Roses excluded.—Only three competitors entered in this class, for which four prizes amounting to £25 10s. were offered. The 1st prize was awarded to Mr. M. Prichard, Christchurch, Hants, for a lovely lot of Liliums, Campanulas, Kniphofias, Crinums, &c. The 2nd award went to Messrs. G. Gibson & Co., Leeming Bar, Yorks., whose exhibit was very good, but the flowers were rather crowded. 3rd, F. Bouskell, Esq., Market Bosworth (gr. Mr. G. Harris).

In a class for a collection of Cactus or decorative Dahlias, having a frontage of 10 feet 6 inches, Mr. S. Mortimer, Rowledge, Farnham, Surrey, easily won the 1st prize. The flowers employed were of average size, clean and very fresh, and were displayed in vases, boards, and on tall Bamboo stands. The 2nd award went to Messrs. Keynes, Williams & Co., Salisbury, who had a much less bright exhibit, due largely to the too free use of Asparagus and hardy foliage. Subsequent to the judging it was found that Mr. Mortimer's collection was not in accord with the terms of the schedule; the 1st prize was therefore given to Messrs. Keynes, Williams & Co., and a special 1st prize recommended for Mr. Mortimer. 3rd, Mr. J. Walker, Thame, Oxon.

The 1st prize in another class, in which any varieties of Dahlias were admissible (similar space to the last-named class), was well won by Messrs. M. Campbell & Son, High Blantyre, N.B. The various sections of Dahlias were well represented in this group, and the flowers were arranged with great taste; 2nd, Mr. J. Walker, Thame; 3rd, Mr. W. Treseder, Cardiff.

Florists' Devices

are always shown well at Shrewsbury. The best Bridesmaids' Bouquet with Orchids, and two Bridesmaids' Bouquets (Orchids excluded) came from Messrs. R. F. Felton, Hanover Square, London. The first-named exhibit was composed entirely of long sprays of Odontoglossums and two white Cattleyas. The Bridesmaids' Bouquets were made of Madame Abel Chatenay Roses. 2nd, Messrs. Perkins & Sons, Coventry. 3rd, Messrs. Gunn & Sons, Olton.

The best Bride's Bouquet, which was composed largely of Odontoglossums, came from Messrs. Perkins & Sons of Coventry.

Messrs. Perkins also beat four competitors in a class for a bouquet of flowers for the hand; 2nd, Mr. W. J. Garner, Hale, Altrincham.

Messrs. R. F. Felton, Hanover Square, London, had the best bouquet of flowers (Orchids excluded), with pink Carnations. Messrs. Perkins & Sons being 2nd, and Mr. John Wilson, Hereford, 3rd.

There were seven entries for a shower bouquet, and after a very close contest Messrs. Perkins & Sons were placed 1st, and Mr. W. Treseder, Cardiff, 2nd

Mr. W. J. Garner exhibited the best "feather-weight" bouquet, which consisted of Oncidiums, Chironia ixifera, &c.; 2nd, Messrs Perkins & Sons.

Messrs. R. F. Felton won the 1st prizes for the best floral harp and floral cross, Messrs. F. E. Smith & Co., Belfast, being 2nd in each case.

O. Robinson, Esq., Alderley Edge (gr. Mr. J. Nixon), beat Messrs. R. F. Felton in a class for a floral wreath.

For an arrangement of cut flowers suitable for a dinner table (4 feet by 4 feet), open to ladies only residing in the county of Salop, Mrs. F. D. Deakin, Belle Vue, was placed in front of seven competitors.

Sweet Peas.

In a class very similar to the above, but in which the flowers used were to be Sweet Peas. Mrs. F. C. Burd, Newport House, beat Mrs. J. Nixon, Alderley Edge, who was placed 2nd. There were 13 competitors in this class.

Liberal prizes were offered by Mr. Robert Sydenham, Birmingham, for flowers shown in his rustic table decorations. There were 14 exhibitors, and after a very close contest Mr. E. Deakin, Hay Mills, Birmingham, was awarded the 1st position for a very pretty table, on which light-coloured flowers were employed; 2nd, O. Robinson, Esq. (gr. Mr. J. Nixon).

In a class for 18 distinct varieties arranged in bunches of about 30 to 40 stems, on a space of 8 feet by 3 feet 6 inches, and for which a 1st prize of £3 and a gold medal were offered, the first prize was won by Mr. J. Gibson, Duns., N.B., followed by Mr. T. Duncan, Duns., N.B.

The first and second prizes offered by Mr. Henry Eckford, Wem, Salop, for eighteen distinct varieties were won by Mr. A. Malcolm, of Duns, and Mr. T. Jones, of Ruabon, respectively. The 1st prize lot included beautiful examples of Evelyn Byatt, John Ingman, and Henry Eckford. Captain Aitken, Duns, had the best dozen vases of Sweet Peas.

Roses.

In a class for a collection of Tea, Hybrid Tea and Noisette Roses, arranged on a space of 4 feet by 4 feet, Mr. John Crossling, Penarth Nurseries, S. Wales, took the lead with a beautiful lot of flowers. 2nd, Messrs. J. Simpson & Sons, Dundee.

Carnations.

In a class for cut Carnations and Picotees, shown with their own foliage and buds, and not dressed in any way, Messrs. M. Campbell, High Blantyre, N.B., took the lead, Mr. C. H. Herbert, Acocks Green, being a good 2nd.

In a similar class, but smaller than the last-named, W. H. Banks, Esq., Kington (gr. Mr. G. Bamford), was first with a very bright collection, Mr. T. Jones, of Ruabon, being 2nd.

The best twelve vases of Carnations or Picotees were staged by Mr. A. R. Brown, King's Norton. His flowers of Chaucer (buff selt), Daffodil (yellow), Iris (yellow round-edged with crimson) were remarkably good. 2nd, Mr. C. H. Herbert, Acocks Green.

Vegetables.

Whilst there were a few collections staged by quite new competitors that were below the usual Shrewsbury quality, these were excusable, because too evidently the products of novices in the art of vegetable exhibition. No doubt, after seeing the superb quality found in the best collections, they went home wiser men. Let us hope before again entering the field as competitors they have taken to heart the object lessons furnished. With regard to the best collections, especially those from the old competitors, they were splendid. Of some it is fair to say they have never been excelled.

Trade Prizes.—Taking these in schedule order, first comes the class for nine distinct varieties, which all the competitors happily read to mean "kinds," for which Messrs. Jas. Carter & Co. offered in six prizes a total sum of £17 10s. There were but six entries, each competitor getting a prize. A good first, however, was that invincible grower, Mr. A. Beckett (gr. to Lord Aldenham, Elstree, Herts). His collection comprised autumn Giant Cauliflowers, Ivory-white Celery, Holborn Giant Leeks, Snowdrop Potatos, Telephone Peas, Ailsa Craig Onions, Duke of York Tomatos, Scarlet Emperor Runner Beans, and Perfection Carrots. Mr. B. Ashton (gr. to the Earl of Lathom, Ormskirk), another first-rate grower, was a good 2nd, having very fine Quite Content Peas, Onions, Carrots, Celery, &c., in his collection. Mr. F. Barratt, Overton-on-Sea, was 3rd.

Messrs. Sutton & Sons' Prizes.—These were offered for collections of nine distinct kinds, were six in number, and amounted to £8 17s. There were eight lots staged, a few also not turning up at the last moment. Here, Mr. Beckett's chief antagonist in the past as an exhibitor, Mr. James Gibson (gr. to the Duke of Portland, Welbeck Abbey, Worksop), the writer of our Vegetable Calendar, was a splendid 1st, having quality of the finest character, such as was worthy of the competitor. It was a matter for regret that these "Greeks" did not furnish the special interest of a keen tug-of-war. Mr. Gibson's collection comprised autumn Giant Cauliflowers, Prizetaker Leeks, Solid White Celery, Superlative Potatos, Best of All Runner Beans, Eclipse Tomatos, Ailsa Craig Onions, Gladstone Peas, and New Intermediate Carrots. Mr. J. Hudson, Leicester, came 2nd, having good Autocrat Peas, Prizewinner Runner Beans, Ailsa Craig Onions, with other good things, in his collection. Mr. Ashton was 3rd.

R. Smith & Sons, Worcester, offered five prizes for collections of nine kinds, but the response was limited. Mr. A. Deakin, Hay Mills, was 1st, and Mr. Ashton 2nd. Quality here was rather moderate, although the total value of the five prizes was £11 15s.

Messrs. Webb & Sons' Prizes.—These again were six in number, and totalled £16 10s. The result was seven collections, each of eight kinds. In this case a younger competitor, Mr. Dymocke (gr. to G. D. Faber, Esq., Wallingford) was well first, the capital quality of his exhibits evidencing a master grower. Viceroy Tomatos, Duke of Albany Peas, Ailsa Craig Onions, Exhibition Runner Peas, Windsor Castle Potatos, Solid White Celery, fine Cauliflowers, and Leeks made up the collection. Mr. Ashton was 2nd, having very fine Masterpiece Peas, Sensation Tomatos, Jubilee Runners, New Guardian Potatos, Cauliflowers, with other kinds. Mr. G. Bastin (gr. to Sir A. Henderson, Bart., Buscot Park, Hungerford) was 3rd. The same firm's prize for a single dish of Tomatos brought five lots, Mr. E. Winchester, Longbridge, having the best in Viceroys.

Mr. E. Murrell's Prizes.—These were five in number, and offered for collections of eight kinds. Mr. R. C. Townsend, Slough, was placed 1st, having in his collection fine Onions, over large Potatos, good Peas, Tomatos, and Beets. W. L. Sewell, Esq., Orleton Hall, was 2nd.

Messrs. W. Bull & Sons' Prizes.—These were quite new here, and in six prizes included a sum of £14 10s. But there was added to the first prize of £5 a silver cup valued at 15 guineas, and to the second prize of £2 a silver cup valued at five guineas. To secure the former trophy was, however, regarded as a coveted prize, hence Mr. A. Beckett seems to have so far thrown his strength here that his collection of nine kinds was of unexampled excellence; indeed, we have never, even at Shrewsbury, seen a finer lot, it was quite without a flaw. There was a centre-back of ten handsome, pure white Cauliflowers, flanked on one side by superb Prize Pink Celery, and on the other with beautiful monstrous Leeks. In front were Alderman Peas, Windsor Castle Potatos, Ailsa Craig Onions, Runner Beans, Favourite Tomatos, and new intermediate Carrots. Mr. Dymocke came a capital 2nd, having very fine Ailsa Craig Onions, Duke of Albany Peas, Runner Beans, Superb Leeks, Tomatos, and Potatos. Mr. Barson (gr. to the Earl of Sandwich), Hinchingbrooke, was 3rd.

Mr. R. Sydenham's Prizes.—These were numerous, including five for collections of eight kinds of vegetables, and about 70 others in small sums for treble, double, or single dishes. The first prize in the collection class was taken by Mr. W. Pope (gr. to the Earl of Carnarvon), Highclere Castle, with fine intermediate Carrots, Windsor Castle Potatos, Perfection Tomatos, good white Celery, Cauliflowers,

Onions, and Parsnips. Mr. F. Barratt, Overton-on-Sea, was 2nd. In the single dish classes, Mr. R. A. Horsford, Llangollen, was 1st for Onions, Turnips, Leeks, Runner and Dwarf Beans, and three dishes of Peas. Mr. W. Pope was 1st for Tomatos, Celery, and Carrots, and he had also several second prizes. As additional valuable prizes in kind are offered to those who obtain the highest number of points in all Mr. Sydenham's classes, it is interesting to record that Mr. Pope had 44, Mr. Horsford 43, and Mr. F. Barratt 36.

Society's Classes.—In the class for twelve distinct kinds for which the society offers the relatively low sum of 4s only, in three prizes, Mr. J. Gibson was here a capital 1st, having a collection of special excellence, much deserving higher value. Gladstone Peas, Perfection Tomatos, Ideal Cucumbers, Prize-winner Runners, Presentation Leeks, Sucham Prize Celery, grand Cauliflowers, Onions, Beet, Parsnips, Turnips and Potatos, made up a faultless collection. Mr. G. Martin was 2nd, and Mr. J. Hudson 3rd. In the class for nine kinds, Mr. Mills (gr. to Captain H. Lonsdale, Shawington Hall) was 1st. Space will not admit of reference to the smaller classes, or to the remarkable display of cottagers' vegetables, always here so exceptionally good.

Messrs. Dobbie & Co., Rothsay, set up, as is now customary with them, a fine collection of 50 varieties of early Potatos in baskets, none large, but all of very high excellence. White varieties included British Premier, Midlothian Early, Eureka, Southern Queen, Peacemaker, The Provost, Dalmeny Early, Milecross Early, and Sir J. Llewelyn; and of coloured varieties, Reading Russet, Beauty of Hebron, Eightyfold, King Edward VII., Crimson Beauty, Rouge Royal, Queen of the Veldt, and Purple Perfection.

Non-Competitive Exhibits.

Messrs. Dobbie & Co., Rothesay, had an extensive exhibit of flowers, representing their excellent double and single Marigolds, also Sweet Peas and Cactus Dahlias. In addition, the firm showed about 50 small baskets of Potato tubers, in which there were some of the varieties that proved best in the recent trials at Marks Tey, such as Midlothian Early, which, although somewhat similar to Duke of York, is stated to be distinct. Southern Queen and some first-class standard varieties were also included.

Messrs. Wallace & Co., Kilnfield Gardens, Colchester, had a magnificent group of hardy flowers, in which the principal feature was a collection of new seedling Montbretias, most of which have larger flowers and better posed on the spikes than the older type. Prometheus is now pretty well known, but Lady Hamilton, of orange-yellow colour, is quite new, also Hereward (yellow) and Lord Nelson (crimson), and others raised by Mr. Davison, at Westwick.

Mr. Albert Myers, Sutton Lane Nurseries, Shrewsbury, showed a pretty group of Zonal Pelargoniums, Coleus, &c., arranged with Abutilon Savitzii and other decorative plants for effect.

Messrs. Dicksons, Chester, had a great bank of hardy flowers, in which most of the species now in flower appeared to be represented. Lilium auratum and Romneya Coulteri were outstanding features of the group.

Messrs. Hobbies, Ltd., Dereham, Norfolk, had an exceedingly long exhibit along the centre of one of the smaller tents. It was composed of climbing and pillar Roses, shown as growing plants, also Dahlia flowers, cut Roses, &c. Cactus Dahlia Princess Mary, of rich salmon-pink colour, is an excellent new variety, and other new ones were included.

Mr. Jno. Cooper, Hardy Plant Nursery, Chipping Norton, exhibited flowers of a good crimson-flowered border Carnation named Roy Morris.

Messrs. Green & Sons, Olton, Birmingham, made a gorgeous display of perennial Phloxes, in which there were numerous varieties of the choicest merit, and many of them very brilliant in colour. The cultivation exhibited was remarkable.

Messrs. Lang & Mather, Kelso, N.B., exhibited flowers of a number of varieties of tree and border Carnations.

Messrs. Thomas Rivers & Son, Sawbridgeworth, Herts, brought some of their choice orchard house fruit trees in pots. Every tree was well laden with fruit, whether of Peach, Nectarine, Plum, Cherry, Apple, Pear, or Grape. The most excellent tree was an extra large specimen of the Dagmar Peach, on which the fruits appeared to have been placed by rule.

Messrs. Richard Smith & Co., Worcester, showed plants of Coniferæ, variegated Hollies, Clematis, &c., in pots, some of the "coloured" Conifers being excellent specimens.

Messrs. Pritchard & Sons, Shrewsbury, made an exhibit of Ferns and other foliage plants, also of Sempervivums, &c.

Messrs. Hewitt & Co., Solihull and Birmingham, displayed a very brilliant group of hardy flowers, in which some of the showiest varieties appeared to excellent advantage.

Messrs. Hugh Low & Co., Bush Hill Park Nurseries, Enfield, had a large exhibit, and one of a kind otherwise but poorly represented at this show. Some of the Cattleyas, Cypripediums, Oncidiums, Miltonia Crashleyana, &c., were good; also flowers of tree Carnations, Fig trees in pots, Abutilons, Codiæums, &c.

Messrs. G. Stark & Sons, Great Ryburgh, Norfolk, exhibited a much variegated dwarf Nasturtium named "Ryburgh Beauty," also Sweet Peas, &c.

Mr. Robert Bolton, Warton, Carnforth, had an exceedingly good display of Sweet Peas in infinite variety.

Messrs. G. Peed & Sons, Roupell Park Nurseries, West Norwood, London, exhibited a group of Caladiums, which consisted of good specimens of large size. The best plants were Oriflamme, Duchess of Teck, Rio de Janeiro, and Raoul Pugno.

Messrs. Bakers, Wolverhampton and Codsall, made the largest exhibit of hardy flowers in the show. It was arranged on the grass in the great fruit tent, and the sorts were massed together in considerable quantities, so that in many instances they appeared as if growing clumps. There were Gladioli, Liliums, Roses, early-flowering Chrysanthemums, Montbretias, Phlox, Hollyhocks, Kniphofias, &c. Messrs. Bakers also showed a charming arrangement of Dahlia flowers, in which most of the types of this flower were shown in various receptacles for the furnishing of good effect. Varieties of the Pæony-flowered Dahlias are very showy, but not of the florist's form.

Messrs. W. Cutbush & Sons, Highgate Nurseries, Middlesex, made a good display of Carnation flowers, most of them "tree" varieties; also plants of Verbena hybrida, "Maiden's Blush," Snowflake, &c., and of the new dwarf Polyantha Rose Mrs. W. H. Cutbush.

Messrs. Webb & Sons, Stourbridge, had an extensive display of indoor flowering plants and cut flowers. Tuberous-rooted Begonias were meritorious, and Sweet Peas, Asters, Gladioli, Carnations, and tall spikes of Hollyhocks were the best of the cut flowers. The new Tomato, "Webb's Emperor," was well shown on arches at the back of the stand.

Mr. Edwin Murrell, Portland Nurseries, Shrewsbury, occupied a large space with a rich collection of cut Roses arranged in bamboo stands, vases, and boxes. He also staged some seedling Gladioli of much merit.

Messrs. Clibrans, Hale, Altrincham, staged a group of double and single-crested Begonias and some well-plumed Celosias of a good strain.

Messrs. Isaac House & Sons, Westbury-on-Trym, Bristol, sent a large bank of hardy flowers, consisting of Delphiniums, Phloxes, Kniphofias, Gaillardias, and Pentstemons.

From The King's Acre Nurseries, Hereford, came an instructive collection of fruit trees in pots, and gathered fruit. In the first-named were noted excellent examples of Marie Louise and Durondeau Pears, The Queen, James Grieve, and Peasgood's Nonsuch Apples, and Muscat of Alexandria and Gros Maroc Grapes. The gathered fruit included good dishes of Apricots, Melons, Plums, and Gooseberries. The same firm also displayed Roses in variety in another part of the same tent.

Messrs. Jones & Sons, Shrewsbury, staged a handsome collection of Carnations, Violas, Show and Cactus Dahlias, and mixed hardy flowers, together with a large collection of Sweet Peas and a table decorated with fruit.

Messrs. Jarman & Co., Chard, Somerset, set up a nice collection of Cactus and Pompon Dahlias, Roses, Centaureas, and some very good vegetables.

Messrs. Rogers & Co., Leamington, exhibited four varieties of large, well-grown Onions.

Messrs. W. and J. Brown, Stamford, Peterborough, showed a collection of hardy cut flowers, consisting largely of Roses, dressed Carnations on boards, and half-a-dozen splendid flowers of Magnolia grandiflora.

Mr. H. Eckford, Wem, staged about a hundred vases of Sweet Peas in capital condition.

Half-a-dozen large baskets filled with double bedding Begonias came from Messrs. Blackmore & Langdon, Twerton-on-Avon, Bath. The varieties Argus, Gladiator, and R. Parsons were smothered with flowers.

Mr. John Forbes, Hawick, N.B., showed a mixed collection of border flowers and Carnations.

An uncommon group of hardy flowers and choice Water Lilies came from Mr. Amos Perry, Winchmore Hill, N.W. A few varieties of hardy Ericas also came from the same exhibitor.

Mr. Joseph Lambert, Dalmeny, Southport, had Carnations arranged in rustic stands, &c.

Double and single-flowered zonal Pelargoniums were well shown by Mr. Vincent Slade, of Taunton. His best varieties were M. Alf Erckemer, Hall Caine, Barbara Hope, Enid, and Chaucer.

Bees, Ltd., Wapping Buildings, Liverpool, showed a group of hardy flowers.

Mr. A. W. Thorpe, Lichfield, sent a representative collection of border Chrysanthemums.

Mr. W. L. Pattison, Cherry Orchard, Shrewsbury, sent Violas arranged in sprays.

A small but good collection of Cactus, Pompon and single Dahlias came from Messrs. Joseph Cheal & Sons, Crawley, Sussex.

Rustic stands decorated with Sweet Peas came from Mr. Robert Sydenham, Birmingham.

Messrs. Tom B. Dobbs & Co., Wolverhampton, occupied a space on the lawn with an arrangement of flowering plants, rustic arches, and arbours.

Honorary Awards.

Large Gold Medals

were awarded to Thomas Rivers & Son, Sawbridgeworth; The King's Acre Nurseries, Ltd., Hereford; and Baker's, Ltd., Codsall.

Small Gold Medals

were awarded to Mr. Amos Perry, Winchmore Hill, N.; Gunn & Sons, Birmingham; J. Peed & Son, Norwood; Robt. Bolton, Carnforth; Hobbies, Ltd., Dereham; Jarman & Co., Chard; Jones & Son, Shrewsbury; and Dobbie & Co., Rothesay.

Silver-Gilt Medals

to Hewitt & Co., Ltd., Solihull; R. Smith & Co., Worcester; Tom B. Dobbs & Co., Wolverhampton; Hugh Low & Co., Enfield; Henry Eckford, Wem; W. Cutbush & Son, Highgate; Dicksons, Ltd, Chester; R. Wallace & Co., Colchester; E. Webb & Sons, Stourbridge; A. Myers, Shrewsbury.

Silver Medals

to John Forbes, Hawick; J. Lambert, Southport; A. H. Thorpe, Lichfield; Vincent Slade, Taunton; J. Cheal & Son, Crawley; W. J. Brown, Peterborough; Robt. Sydenham, Birmingham; Isaac House & Son, Bristol, and Clibrans, Altrincham.

Bronze Medals

to Laing & Mather, Kelso; Blackmore & Langdon, Bath; Bees, Ltd., Liverpool; G. Stark & Son, Great Ryburgh; W. L. Pattison, Shrewsbury; Pritchard & Sons, Shrewsbury; Rogers & Co., Leamington Spa; and R. F. Felton, Hanover Square, W.

Certificates of Merit

were awarded to Mr. W. Treseder, for Dahlia Peter Treseder; Messrs. Blackmore & Langdon, for Delphinium Harry Smetham; Hobbies, Ltd., Dereham, for Ampelopsis Henryana, Rose Hiawatha, and Cactus Dahlias, Princess May, Queenie, and Williamsoni; Messrs. Keynes Williams & Co., Salisbury, for Cactus Dahlia, Kathleen Bryant, Coradog; J. Cooper, Chipping Norton, for Border Carnation Roy Morris; Baker's, Codsall, for Viola, Jessie Baker; R. Wallace & Co., Colchester, for Montbretias Westwick, Herewood, Lord Nelson, and Lady Hamilton; Amos Perry, Winchmore Hill, for Calla Mrs. Roosevelt, and Dobbie & Co., Rothesay, for Cactus Dahlia Dreadnought.

SOBRALIA AMESIAE, FLOWERS YELLOWISH-BUFF FLUSHED WITH ROSE, FROM MAJOR HOLFORD'S COLLECTION.

FORCING FRUIT TREES IN POTS.

THE culture of fruit trees in pots is not such a novelty as it was some few years ago. Nevertheless, I think many growers hesitate before embarking upon this system of fruit growing for various reasons, peculiar, perhaps, to their own cases. Some may think that the crops will not be commensurate with the pains and labour bestowed on them. To such let me at once state that this, providing the pot trees are given suitable conditions, is a mistaken notion. Others may think that pot trees are not of a lasting character. Here, again, a popular error is made, as I have proved after several years' experience. As an instance of their long life I may state that the original tree, in a pot, of Lord Napier Nectarine introduced into cultivation by Messrs. Rivers and Son more than 30 years ago only succumbed to old age about three years since. Some persons imagine that the flavour of forced fruit from pot trees is not of the first quality, and I have often had questions on this point put me. This also is a mistaken idea; the flavour is, in fact, often better from pot-trees than from those grown upon the planted-out system. One distinct advantage lies in the fact that a greater range of varieties of any given kind of fruit can be cultivated under the pot system than under any other, and, thereby, a better succession can be maintained. Everyone admires large, finely-trained trees of Peaches and Nectarines which bear heavy crops of fruit, but there is the disposal of such large crops to be considered whilst the fruit is in the best condition for dessert purposes, as the fruits ripen more or less at one time, but even where several trees of any given variety of fruit are forced in pots, it is not often that they ripen simultaneously. Again, when a planted-out tree has ripened its crop of fruits the plant-house cannot be turned to such further uses as when pot trees are grown. In this matter, therefore, the latter have another distinct advantage. At Gunnersbury we have adopted the forcing of trees in pots for several years, and find that it answers admirably. At first I was doubtful if it would be a success. I had, in common with many other gardeners, seen the splendid examples of fruit trees in pots staged at the Temple Show and elsewhere by Messrs. Rivers and Son. I took up the forcing of fruit trees in pots at the instigation of Mr. Leopold de Rothschild, who had so often seen the trees staged by the firm just named. After a year's experience I plainly saw there was more value in the system than I had at first imagined, and the number of trees for forcing in pots was, therefore, extended, and the number of houses devoted to their culture also. With us it is now reduced to a regular system to suit the special supplies required. We usually have dessert Cherries ripe by the end of April. Our Nectarines begin to ripen the first week in May, and these are closely followed by Peaches and Plums. It is to these four kinds of fruit that I wish to direct my remarks. When once we commence to pick ripe fruit we aim at getting a succession throughout what is termed the "London season," in other words, to the end of July, or thereabouts. Of course, during the latter part of this period the trained trees in the borders also come into bearing. Indoor Cherries are finished by the middle of June, when the outdoor crop becomes available.

CHERRIES.

Of these fruits we find the earliest and most reliable variety to be Guigne d'Annonay, and this is very closely followed in its period of ripening by Belle d'Orléans. The former is quite sweet and good when of a dark red colour, but it is perfection when black. It is of medium size, and it has a small stone. Frogmore Early Bigarreau and Governor Wood follow in close succession; both of these are very fine in flavour and very similar in appearance. Early Rivers and Bigarreau de Schrecken are the two finest black Cherries for pot culture, both kinds being large, fleshy, and of first-class flavour. In addition, we grow a few trees of May Duke, as it produces much pollen, which is useful for fertilising purposes.

NECTARINES.

We rely entirely upon Cardinal for our earliest crops of these fruits. It is fully ten days earlier in ripening than Early Rivers, which is itself the same number of days in front of Lord Napier. Cardinal, as indicated by its name, develops a remarkably fine colour. It is a heavy cropper grown in pots and the fruits are of fine flavour, but it possesses a somewhat clingstone character. This defect is also to be detected in Early Rivers, but, in my opinion, it is no detriment in either case. Early Rivers, when fully matured in pots, is a grand fruit. To follow these we have both Lord Napier and Advance. The latter variety is not so well known as its merits entitle it to be. Next, Pineapple and Humboldt come into use. Both of these kinds crop freely, and their good flavour is well known, whilst they both keep well when ripe.

PEACHES.

Our two earliest Peaches are Duchess of Cornwall and Duke of York, both reliable as good croppers. I have, however, yet to learn which is really the better of the two; the last-named has the best reputation. Amsden June is also a useful variety, but it is not always reliable; neither is Hale's Early, a good and handsome Peach where it thrives well. I am very partial to Dr. Hogg as a second early variety; with us it always crops freely. It is also valuable for its abundant pollen. As a flowering plant only it is most ornamental. Peregrine, one of the more recent of Messrs. Rivers' introductions, promises well. It sets freely and possesses an excellent constitution, so far as I have been able to form an opinion.

PLUMS.

Of Plums the earliest is Early Prolific. This usually ripens about the middle of May, and although it is not of first-class flavour it is valuable from its earliness as well as for its free cropping qualities. To follow, I find nothing equal to Early Transparent Gage, which is a most valuable variety to grow, both for its high-class flavour and for the freedom with which it crops year after year; rarely does it fail. Grown in the same house with Cardinal Nectarine, it ripens about 14 days later. Golden Transparent Gage, which, in my opinion, is the finest of all Plums for pot culture, succeeds it. This variety is likewise a good cropper, whilst for flavour and appearance it is unsurpassed. Two other excellent kinds are Kirke's and Jefferson's. Of these two I prefer the latter; both well-known dessert varieties. As a later kind we grow Reine Claude du Comte d'Althann, which is a very fine Plum when fully matured. I would strongly recommend the cultivation of Plums in pots, for they are most amenable to this method of cultivation. They succeed well under the same treatment as Peaches and Nectarines, whilst for fruit-bearing qualities they are not to be surpassed.

ORCHARD HOUSES.

The best possible form of house for the forcing of fruit trees in pots is the span roof. Our houses face nearly south and north, and I think, all things considered, it is the better position, for the southern side thus ripens earlier, and thereby a succession is ensured. For later crops I think houses facing east and west are preferable, but it is not an essential point. Lean-to houses are not to be recommended, for in these the plants have a tendency to grow towards the light. Three-quarter span-roofed structures are a good medium between the other two, especially if back ventilation is provided. It is essential to secure a free circulation of air, for nothing is more harmful to these fruit trees than a close, confined atmosphere. Our span-roof houses have provision made for side ventilation in a continuous manner from end to end. This is provided by means of wooden shutters about 20 inches in width. These are hung, not at the top, as is the common fashion, but at the bottom; thus the inlet of a cold current of air is greatly overcome. Even in cold, windy weather side ventilation can

be given without any fear of evil results. Above these ventilators we have glass, but this is a fixture, varying in width from 18 inches to 2 feet. The glass is butted end to end, being only bedded at top and bottom, thus the maximum amount of light is ensured. But three or four courses of brickwork appear above the ground, and upon this rests the woodwork to which the side ventilators are hinged. The top ventilation is provided by means of small or medium-sized lifting lights, at intervals to the extent of about one-fourth of the entire length of the roof. Continuous top ventilation is not, in my opinion, needed; it would, I think, create more draught than is advisable. The houses should be lightly constructed, the present system of tie-rods in a great measure dispense with much heavy woodwork. I am not an advocate of very cheap houses of inferior material, but I do most certainly disapprove of useless expenditure in erections intended for utilitarian purposes. Houses of ornamental construction are not needed for practical cultivation. Our glass is cut all to one size, viz., 15 inches by 20 inches, and it is always of good quality, for this I consider essential. No staging is provided, nor is any required, for the use of stages only complicates matters. We stand our plants upon a gravel bottom, using slates, tiles, or bricks to place under the pots when required. If the house be a wide one, i.e., one in which the trees cannot easily be attended to by means of one central path, two paths are provided with a row of trees—the dwarfest—next the front. In other houses not so wide a central path only is provided. Brackets and swing-shelves are fixed, these being used for Strawberries. In the narrower houses the pipes are fixed around the sides, one above the other, with a smaller pipe (3 inches) sunk near the path. In the wider houses the pipes are laid flat around the sides, with room between them for one row of trees; in these the central bed has a 4-inch flow and return pipe around it. A sufficient quantity of piping is provided to afford the requisite temperature without making the pipes unduly warm. For making the paths gravel is used, the aim being to secure a moist bottom throughout. Large rain-water tanks are provided under the beds in order to catch all the rain-water possible. I consider the use of rain-water for these trees most essential. *James Hudson.*

(To be continued.)

GLADIOLUS "MRS. CECIL BARING."

THIS variety was shown by Messrs. Kelway & Son at the meeting of the Royal Horticultural Society on August 14, being one of four varieties which gained Awards of Merit. The flowers are of very large size and of lemon-yellow colour, except the base of the lower petal, which is densely spotted with red. This lower petal forms a distinct lip to the flower, whilst the uppermost petal is much reflexed. The flower-bearing portion of the spike was 18 inches to 2 feet long.

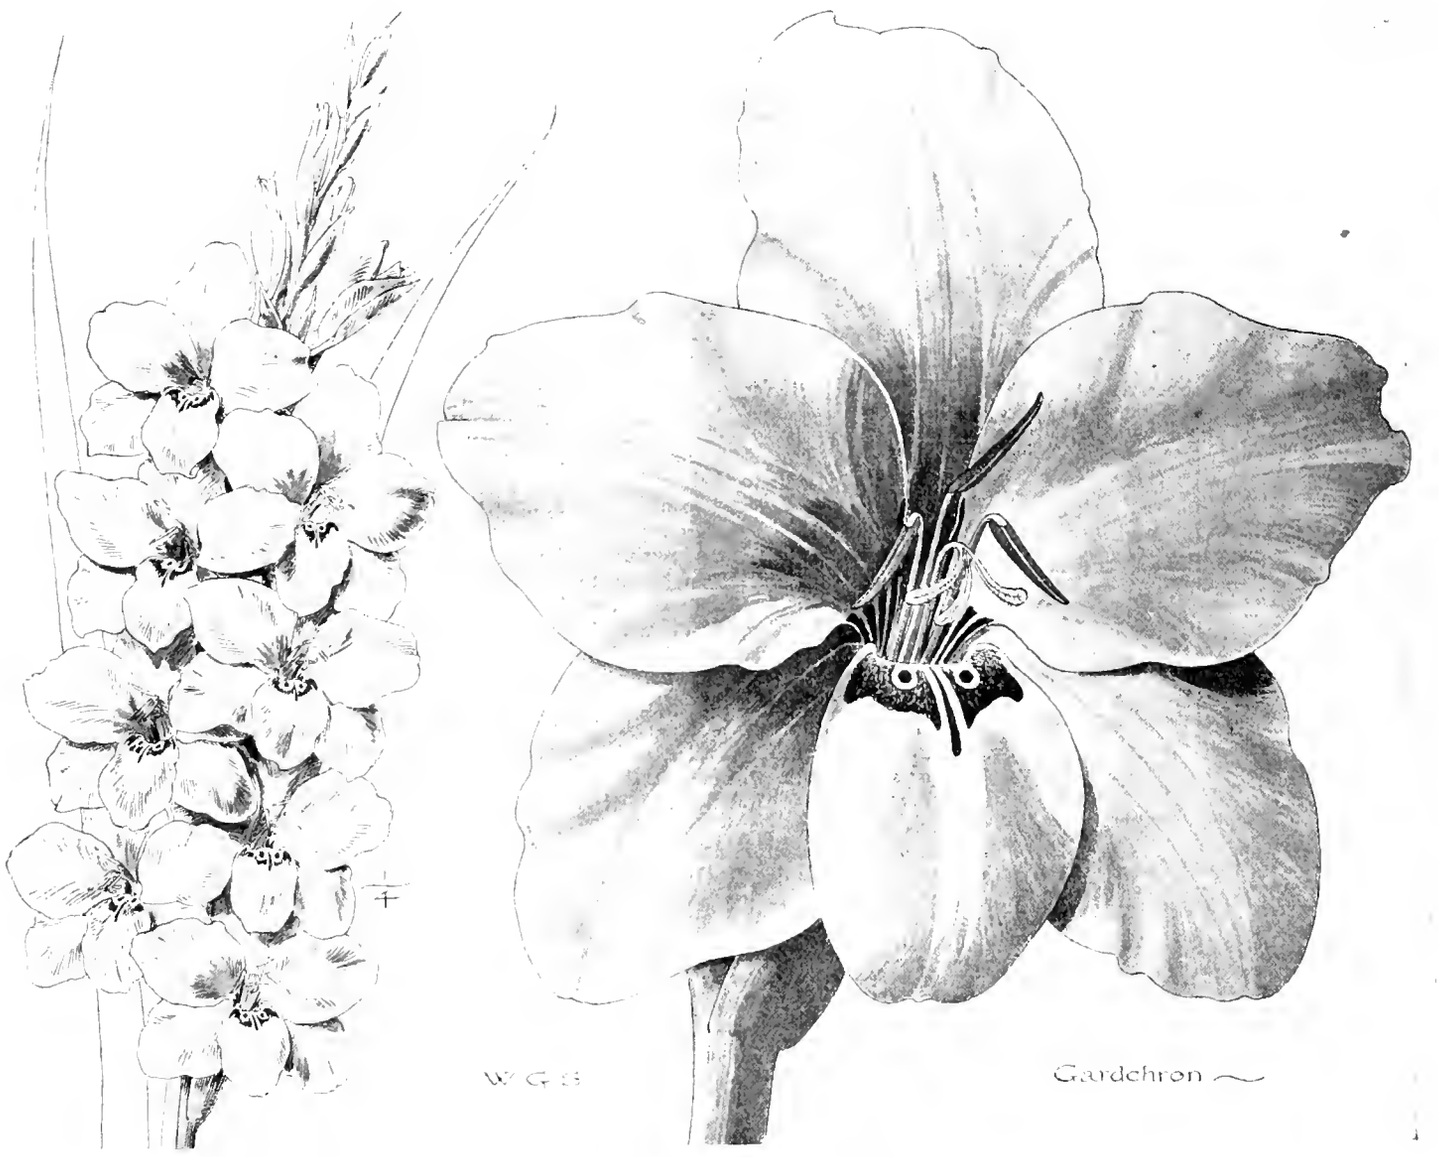

FIG. 63.—GLADIOLUS "MRS. CECIL BARING": COLOUR OF FLOWERS LEMON-YELLOW, SPOTTED WITH BRIGHT RED.

NEW OR NOTEWORTHY PLANTS.

HEMEROCALLIS FULVA, NEW VARIETIES AND HYBRIDS.

HEMEROCALLIS fulva shows many fine natural varieties; the double forms, such as disticha fl. pl. and Kwanso fl. pl., from Japan, are well known in gardens. Some years ago Mr. C. Sprenger introduced certain new and very fine varieties from Central China. The first was the unfortunately named "maculata," from Shen-shi. The flowers are larger, brighter in colour, and the blotch more marked than in the common type. The plants are here a week later in flowering, and seed freely, and have given many very distinct and interesting hybrids; as far as I know, the first of the fulva class, of which I will speak later on.

The second form is var. "Cypriani," from Hupeh, very distinct, dwarfer than the common fulva and than maculata, and very floriferous. The flower is coppery red with a golden centre and a well marked golden line down the middle of the petals; the form is gracefully reflexed

The third new variety is "hupehensis"; this is the brightest of all, flowers very reflexed and undulating, bright coppery red, with a yellow throat.

H. × fulcitrina (fulva maculata × citrina), the first hybrid from fulva crossed with another Day Lily. Fulva maculata is the seed parent, and H. citrina, a Chinese species introduced some years ago, is the pollen parent. It is a fine series of plants, showing all shades, from light coppery red to dark yellow; the petals long and narrow as in citrina, or even broader than the seed parent All these hybrid varieties are good additions to our hardy plants. *William Muller, Vomero, July 27, 1906.*

A CORNISH TRIP.

STRANGE to say, though an ardent Fern-hunter for nearly 30 years, I had never set foot on Cornish ground until recently, Devonshire, the Lake District, and Scotland being selected year after year, more often than not for other reasons than ferny ones. My old friend Mr. George Bunyard gave me, however, such a glowing description of waist-high Hartstongues and Blechnums and shoulder-high Lady and Male Ferns, to say nothing of first-storey-high Tree-Ferns in all their native glory, though transplanted to Antipodean paradises, that I half resolved to go and see for myself, and the other half of the resolution was clapped on instanter when I found I could have as a congenial companion Mr. George Nicholson, of Kew Gardens fame. Despite my warning that he would be unutterably bored, as a ferny lane a mile long would take me half a day to investigate, he did not quail at the prospect. As a result, Falmouth was selected as our destination pending the choice of a still fernier one, and eventually we settled down in Penryn, a couple of miles outside that ancient port. Falmouth itself is hardly a Fern paradise, and yet, curiously enough, I found a pretty crenate marginate variety of Hartstongue snugly ensconced in a chink in a stone wall facing the main road. Find No. 1. The river Fal, like all the so-called Cornish rivers towards the Lizard, is really an arm of the sea stretching inland, and, in this case, fetching up short at Truro with a meandering series of cuttings and docks adjacent to a bridge, which indicates, presumably, a river proper on a small scale higher up, though a sudden thunder plump prevented us from landing and ascertaining the fact. The streets of Falmouth are tortuous, narrow, and steep, the town seeming to be built on a switchback system of levelling, and as some 30 of our finest ironclads and a swarm of destroyers happened to be in port the atmosphere was nautical in the extreme, and a glimpse of the port itself showed it to be pervaded with little boats and big boats, jolly boats, and dinghies impelled by electricity and petroleum, steam and elbow-grease in all directions, laden with cabbages, conger-eels, loaves of bread, and all kinds of comestibles and probably drinkables, which were being transferred from terra firma to the fleet aforesaid. All this, however, is presumably common to most seaports, but it is not everywhere that one can turn a corner and suddenly confront a house literally covered as to its front walls with ivy-leaved Pelargoniums smothered with bunches of brilliant rosy bloom and soaring upwards 20 to 30 feet from the ground, while every here and there in the gardens we get a peep into there are Palms (Chamærops), Agaves, Cordylines, and many other plants demonstrating that the climate differs materially from that of the eastern coasts and inland generally. Of these, however, more anon, for the glimpses here were but a meagre foretaste of the glorious vegetation we witnessed in more favoured localities. Thus one of our first visits was to TREGOTHNAN, the seat of Lord Falmouth, a few miles up the Fal river, whence the palatial mansion is seen crowning an eminence on the right bank as we ascend. Access to the estate is obtained from the steamer by a boat, in which Mr. Andrews, the head gardener, was awaiting us. From the sea the whole estate, save the long avenue-like clearing in front of the house, appears to consist of dense rounded masses of low-growing Oaks, which cover the sea faces of all the hills hereabouts and mask, as we subsequently found, an infinite wealth of Fern life. Land-

[Photo by G. Nicholson.

FIG 64 TREGOTHNAN

ing, we climbed a pretty steep slope forming a carriage road, bounded on one side by a high bank teeming with Hartstongues, Shield Ferns, and several other species, while under the trees and among the shrubs huge specimens of these, together with Lady Ferns and Male Ferns, formed a veritable jungle, to which later on some splendid Dicksonias added an Antipodean touch. It is, indeed, in this particular direction of intermixture of our native plants, shrubs, and trees with semi-tropical ones in the open air that we find one of the main features of interest in Cornwall, and it is doubtless due to the cultural facilities thus afforded that we find so many splendid gardens dotted about the country, in most of which the vegetation reminds one forcibly of that of Mediterranean resorts. Naturally, under such conditions a visit to a number of such, each with its particularly grand specimens of exotic growths, render it somewhat invidious to specify this or that specimen as eclipsing all others. Hence, while recognising the kindness of Mr. Howard Fox, Rosehill, whose gardener, Mr. Jenkins, accompanied us round his charming garden, where the birds are so tame as to take crumbs from the hands of his visitors, of Mr. Andrews, of Tregothnan; Mr. Smith, of Penjerrick; Mr. Rundle, of Basahan; and Mr. Gill, of Tremough, we are compelled, with a few exceptions, to lump together the chief examples of sub-tropical growths which we noted. One special exception was Datura suaveolens in Mr. H. Fox's garden, a magnificent specimen 60 feet in circumference, and, like a smaller companion, crowded with hundreds of the long trumpet-shaped and warmly tinted flowers of this species. A giant Cordyline here, with a massive trunk 2 feet in diameter, is probably the finest specimen in the country. Among the exotic Ferns here Lomaria magellanica, Dicksonia antarctica, Woodwardia radicans, and Cyrtomium falcatum were in grand form, and were, of course, accompanied by innumerable native species. It was, however, at Basahan, on the Helston river, the estate of Sir A. P. Vivian, C.B., that we saw the nearest approach to a New Zealand Fern prospect, since here, in one secluded valley, scores of fine examples of Dicksonia antartica form a dense roofing of fronds by their intermingled plumes, while the soil is even more densely covered with huge Hartstongues and other native Ferns intermingled with dwarf Palms, which have been liberally planted, and promise some day to create a monopoly at the expense of their neighbours. Secluded pools or lakelets surrounded by elsewhere tender exotic trees and shrubs and fringed with luxuriant masses of the white Calla Ethiopica imparted quite a tropical appearance to the prospect, and one would hardly have been surprised to see the snout of an alligator poke out as a specimen of appropriate fauna, though nothing worse than the native frog appeared to shock us. Osmunda regalis was, of course, entirely at home, and in a ferny jungle in this district a magnificent revolved and crispate variety of Lastrea filix mas fell to Mr. Nicholson's lot as a striking example of the surprise kind which now and then rewards the British Fern-hunter; a waist-high specimen and utterly different from any of its neighbours of the same species. Curiously enough, a hunt through thousands of robust Hartstongues failed to yield anything better than half-and-half attempts at a marginate form not worth having, although under such congenial environments a thoroughbred frilled form (S. v. crispum) would suggest itself as a most appropriate response. Our finds hitherto had been several prettily crested forms of this species (not the merely forked or "lobatum" type, which is common, but thoroughbreds), all found in a very small state on old walls or chinks, where luxuriant growth was impossible. Thus one was "spotted" by Mr Nicholson high up under a railway arch, just within reach of a stick, another by myself in a dry hedge, and a third in a stone wall by the roadside, a slender-fronded polydactylous form. This led my companion to propound the theory that variation might be due to restricted growth; a theory, however, subsequently withdrawn when the big Lastrea aforesaid turned up, and certainly not accepted by the writer in view of his experience and knowledge of robust varietal finds elsewhere. In a churchyard at Penryn, a marked submarginate, or, rather, sublineate variety of Hartstongue was found, and within a few yards from it a very narrow fronded form, both these being within less than a hundred yards of the slender polydactylous variety above cited, which was found outside the boundary wall of the churchyard in question. Polypodium vulgare, contrary to expectations, was extremely constant to the normal type; no examples of bi-pirmation cropping up, such as are so frequently noted in Wales and Ireland. An old wall in one of the Penryn lanes had, however, two widely separated colonies of an erratic variety, in which nearly every frond was either ramose or bifid or with

serrate pinnæ at the base, or eccentric in some way. Under culture this has retained its eccentricity. The two colonies were some 30 or 40 yards apart, and consisted of a large number of independent plants, a fair proof that the spores reproduced the erratic type. A promising lineate form of Asp. ad. nigrum was found in a hedge, but requires proving. Altogether the 9 days yielded 14 varieties worthy of trial, and the bulk of these have proved themselves true by subsequent growth. L. æmula was rare, and the first find, an unexpected one and very robust, among a lot of L. dilatatas, was actually carefully lifted as a crispate foliose variety of the latter species before the recurved pinnules undeceived us, and the finding of another clump in the vicinity removed all doubt, when the "find" was replanted with a pang of disappointment. Among the most striking plants observed growing in the open in the several gardens we visited were Woodwardia radicans, Lomaria magellanica, Dicksonia antartica, all in best possible form, Solanum crispum, S. Wendlandii, Datura suaveolens, Abutilon vitifolium, Citrons bearing large fruits, Olearia argyrophylla, O. macrodonta (10 feet through and a mass of white flowers), Pittosporum Tobira, Cordyline australis, flowering freely, Fragaria indica with yellow flowers, Viburnum rugosum, Semell (Ruscus) androgyna growing most luxuriantly, clambering over adjacent trees and shrubs, and bearing fringes of yellow flowers on its leaflike bracts. Sempervivum holochrysum, with grand bunches of yellow flowers, Solanum aviculare, rich purple blue flowers, Azalea indica myoporum lactum, with profuse pellucid dots on the foliage, Desfontainia spinosa, Lapagerias rosa and alba, Rhodochiton volubile, with purple red calyces, Arundo donax, Leptospermum scoparium, with thousands of white flowers, Grevillea rosmarinifolia, red-flowered 16 by 6 feet, very fine; Arundinaria fastuosa, with canes 1¼ inch in diameter, Chanthus puniceus in splendid form, Teucrium fruticans, avenues of Camellias, and innumerable other exotics, which elsewhere in these islands require glass culture and winter warmth, while here they are as robust and rampant as in Madeira or similar warm habitats. *Chas. T. Druery, V.M.H., F.L.S.*

LILIUM NEILGHERRENSE: THE NILGIRI LILY.

This rare and stately species, with blossoms 11 inches in diameter, can be had in flower from July until November; but, unfortunately, it is not easy of culture, and is therefore seldom successfully grown. I send a photograph of flowers produced on bulbs raised in England from small offsets, the original bulbs having been sent me direct from the Nilgiris ten years since. This bulb, like most of those imported from the East, had been deprived of its lower roots—a proceeding that entails severe loss to the plant, which, in consequence, makes little growth during its first season after the operation. One meagre flower, almost without foliage, was produced the first year; but it was cut off before it had faded, and the bulb was placed close to the glass of a warm vinery and encouraged, by careful watering, to mature itself. A slight top-dressing of rich soil was added to the surface, and it was many weeks ripening its stem and bulb before it went to rest. For a short time it was kept almost dry, in a minimum temperature of 45°, until signs of growth began (in April), when more rich top-dressing was added, and a strong stem, with ample foliage and one large bloom, was produced, with several small offsets surrounding the original bulb.

During the next spring the bulb was repotted low down in a 9-inch pot that was provided with good drainage, the compost consisting of peat, loam, and leaf-mould in equal proportions, charcoal in small lumps, sand, and bone-dust being added in moderate quantities. The offsets were removed at the same time and grown on in the same manner as the large bulb, until they had attained their flowering size, when each produced two blooms on a stout stem, of far greater vigour than those from the original bulbs.

The bulbs are not repotted every year, and they usually succeed best when left for two years in the same pot, their wants being supplied by fresh top-dressings.

In this way it is not difficult to work up a stock of this magnificent Lily at home, although the supply of bulbs from India is very limited. The usual mistakes in growing it are two-fold. It is the common practice to "dry off" the bulbs of Liliums directly after flowering, but every leaf on the stem should be kept green until they show signs of having completed their work. A large quantity of water is not, however, required by the maturing bulb, and it is therefore necessary to supply its wants with judgment. All the sunshine possible, with sufficient fire-warmth in winter, should also be supplied during the long period of ripening.

The other usual error is to repot the bulb yearly. All Liliums resent disturbance at their roots, and especially injury to the thick, fleshy roots below the bulb. They should, therefore, be given sufficient room (in repotting them) to allow of several renewed top-dressings, with plenty of tepid water and liquid manure during their time of growth. *J. L. R.*

[A fine illustration of this Lily was given in our columns on July 20, 1901.]

LIME IN SOILS.

It has long been recognised that the lime in soils is subject to regular loss. This is owing to the carbonic acid which is present in rainwater, and also that which is constantly being formed in the soil itself acting as a solvent to any lime which may be there, and so removing it into the drains or to the general stock of underground water and out of the reach of roots of most garden crops. Ordinary garden soils which contain upwards of one per cent. of lime and but little organic matter are subject to a normal loss of carbonate of lime in the drainage water amounting to about 800 pounds per acre every year. Most of the carbonate of lime present in soils has been derived either from the natural chalk formation of the district, or from artificial applications of chalk to the land, or dressings of quicklime and marl.

The loss of this carbonate of lime in soils is increased by the use of manures containing sulphate of ammonia, low grade acid superphosphates or coal ashes, but is diminished by the use of nitrate of soda, basic slag, farmyard and stable manure, and vegetable débris.

The Rothamsted agricultural experiments show that manuring the land with organic manures, such as stable manure, rape cake, shoddy, dried blood, skin and bone manures, &c., and the growth of Peas, Beans, Clovers, and other leguminous crops which leave behind in the soil a considerable residue of roots rich in oxalate of lime, or the débris of plant-root tissues which accumulates in the soil of grass-land, or of fields laid down to temporary pasture, all go to maintain the stock of carbonate of lime, which in its turn is being as constantly drawn upon for nitrification purposes by the micro-organisms in the soil, and for the neutralisation of the acids produced during the bacterial decay of the organic matters which the soil receives in manures.

Further, the normal growth of crops tends to restore a certain amount of carbonate of lime and of carbonate of potash to the soil, because the plant in feeding upon the various salts dissolved in the soil by the rainwater, melted snow, and minor deposits, takes more of the acids than of the lime or potash, leaving behind a basic residue of lime or of potash, combined with carbonic acid excreted from the roots of the growing plants. Experimental research has shown that with ordinary garden crops the restoration of lime and of potash base in the before-mentioned fashion must be considerable, probably supplying sufficient base for the nitrification processes which are always going on in the soil beneath our feet. The soil is not a dead, inert mass, but a laboratory of living germs which are always working for the benefit of man, or for the development of the higher descriptions of plant-life.

These facts go to explain why many soils containing little or no carbonate of lime yet remain healthy under ordinary garden cultivation, provided that acid manures or coal ashes are not used on them.

In old garden soils and market gardens, to which large quantities of farmyard or stable manure or peat-moss litter are constantly applied, there is a danger of these becoming sour, provided but little natural lime exists in them. In this case an application of crushed chalk, 2 000 lbs. per acre, or of ground quicklime, 1,000 lbs. per acre, or of basic slag, 500 lbs. per acre, or a liberal dressing of old mortar rubbish, is to be recommended. Any one of these may be applied in the winter or early spring, and dug or ploughed in, so as to get them well incorporated with the soil. One application of these materials given once in five years would, in most cases, be sufficient. For fruit trees and for Vines 8 ozs. of bone-meal may be given once in each two years to each square yard of land immediately under and around the stems according as the surface roots may have extended.

In garden soils which are subject to the club-foot disease, or to the "finger and toe" fungus, it is a sure indication that the soil is in want of lime, and an immediate application should not be neglected. It is also necessary that the diseased plants be taken up and burned; do not put them upon a manure heap, or into a pig-sty, because the disease would be again returned to the soil, and in a more virulent form. *J. J. Willis, Harpenden.*

NURSERY NOTES.

MESSRS. A. CAMACHO & CO.'S ORCHID NURSERY, BRIGHTON.

A few years ago Messrs. Camacho commenced to import Odontoglossum crispum in very large quantities, selling the importations at Messrs. Protheroe & Morris' Auction Rooms, Cheapside. The success of the early importations, and the beauty of some of the spotted varieties which flowered out of them, induced the firm to start their compact block of 11 long span-roofed houses in De Montford Road, Brighton, in order to test at least a fair proportion of their importations and some of the collections from new districts, Mr. Bogaerde, well known both in England and on the continent as a clever Orchid expert, undertaking the management. Consequently the establishment can now boast over 60,000 unflowered plants of Odontoglossum crispum, of which some 12,000 are freshly imported and the remainder are in various stages of establishment approaching the flowering condition. The houses are not arranged for show purposes, and the plants until proved are kept in small pots, closely placed on the staging to economise space. As the spotted forms flower they are potted on and placed on inverted flower-pots, and in that way quite a valuable collection is arranged in one of the houses.

At present but few are in bloom, but four very nicely blotched varieties were among them, one

small and weak plant having a very finely-formed white flower densely blotched all over with light red-brown, a tint which Mr. Bogaerde expects will deepen when the plant produces fully developed flowers. The batches are kept together as imported, and it is curious to see how some peculiarities may be traced in each batch by which they can be distinguished from others collected in localities so near together that no difference could have been expected. One batch of 4,000 plants with red-brown bulbs is being carefully watched, as the few of them which have already flowered have been spotted varieties, and another in bud is heavily blotched and very promising. One batch has not yet produced any with spotted sepals and petals, but an unusual proportion of varieties with large and finely spotted lips, the three now in flower well showing that peculiarity. The plants of another set are prolific in good forms of O. Adrianæ and, as usual in that case, O Hunnewellianum is also present with the O. crispum. Some good O. loochristiense have also appeared with a very close affinity to O crispum, but with yellow-ground colour blotched with brown.

The culture of Odontoglossum crispum may be said to be the main object of the nursery, but there is also a fine batch of a good type of O. Pescatorei and smaller lots of several of the showiest Colombian species.

Two long houses are also filled with established unflowered Cattleyas, the first having a very fine lot of C. Trianæi in sheath, including a large mass imported as a large, pure white variety; and the other an equally good lot of C. Warscewiczii from a new locality, and which are said to come with a recommendation from the collector, and dried flowers, which render it desirable to prove them before selling.

NOTICES OF BOOKS.

MUSHROOMS, AND HOW TO GROW THEM. By John F. Barter (J. F. Barter, Ltd., Napier Road, Wembley, R.S.O., Middlesex).

We advise those of our readers who want to grow Mushrooms for sale or home consumption, and who are hesitating owing to lack of knowledge, to purchase this small octavo volume of 44 pages and consistently to follow the simple instructions therein given by a man who has made a good living by Mushroom culture and the making of the spawn from which the esculent springs, and who has 40 years' experience behind him. He is a firm believer in the open-air treatment of the Mushroom, and gives full directions for making the beds (ridges) and spawning a meadow, as the case may be. His practices in some points differ from our own, but then, before such a master of the craft one must be silent. The spawning of the beds or ridges should not be done till the warmth has sunk to 75° as proved by the plunging thermometer. We used to spawn beds at 98° and a degree or two less. The remarks on the casing soil are very much to the purpose, many a failure in Mushroom growing being traceable to the use of unsuitable soil. Another thing to avoid is impatience, the Mushroom being an erratic esculent. "Sometimes," says Mr. Barter, "a crop will come in a month or in six weeks. On the other hand, we have known beds made in November to delay bearing until the following April, and then to produce splendid crops." There are pithy little paragraphs on Testing the Heat of Ridges, Gathering, Digging out Stalks, Frequency of Gatherings, Grading, Packing, Marketing, Mushrooms in Sheds, in Vineries, Cellars, and all full of useful remarks by a man of observation. This one will serve. The spawning of a meadow by two men would, in the case of a prosecution for trespass, be taken as evidence of the land being "cultivated."

OSMUNDA PALUSTRIS VAR. MAYII.

THIS very remarkable form originated in a sowing of Osmunda palustris in the nursery of Mr. H. B. May, Edmonton, and was awarded a First Class Certificate by the Floral Committee of the Royal Horticultural Society at the Holland House Show in July last. As will be seen by the illustration, the normal type of the species is replaced by a peculiar "ramo-cristate" form of the pinnæ, while the pinnules are contracted and crispate, the result being a very novel form of cresting or tasseling. A further variation is a broad band of white along the midribs, curiously suggesting what is probably an impossibility, viz.: a cross between Osmunda and some one of Mr. May's variegated forms of Pteris, which in this respect is closely imitated. Although originated, as stated, in a sowing of O. palustris, the plant presents many of the characters of O. regalis, which are emphasised by the subsequent appearance of the peculiar terminal fructification common to both species, but in this case more on the lines of O. regalis than of O. palustris, while the folia- [illegible] more to the former than to the latter [illegible]. It O. regalis, it may be a secondary [illegible] well known O. r. cristata, but this is an open question. In any case it is a very [illegible] Fern, and considering the constant [illegible] either species, a distinct acquisition as a hardy Fern of easy culture. *C. T. D., V.M.H., F.L.S.*

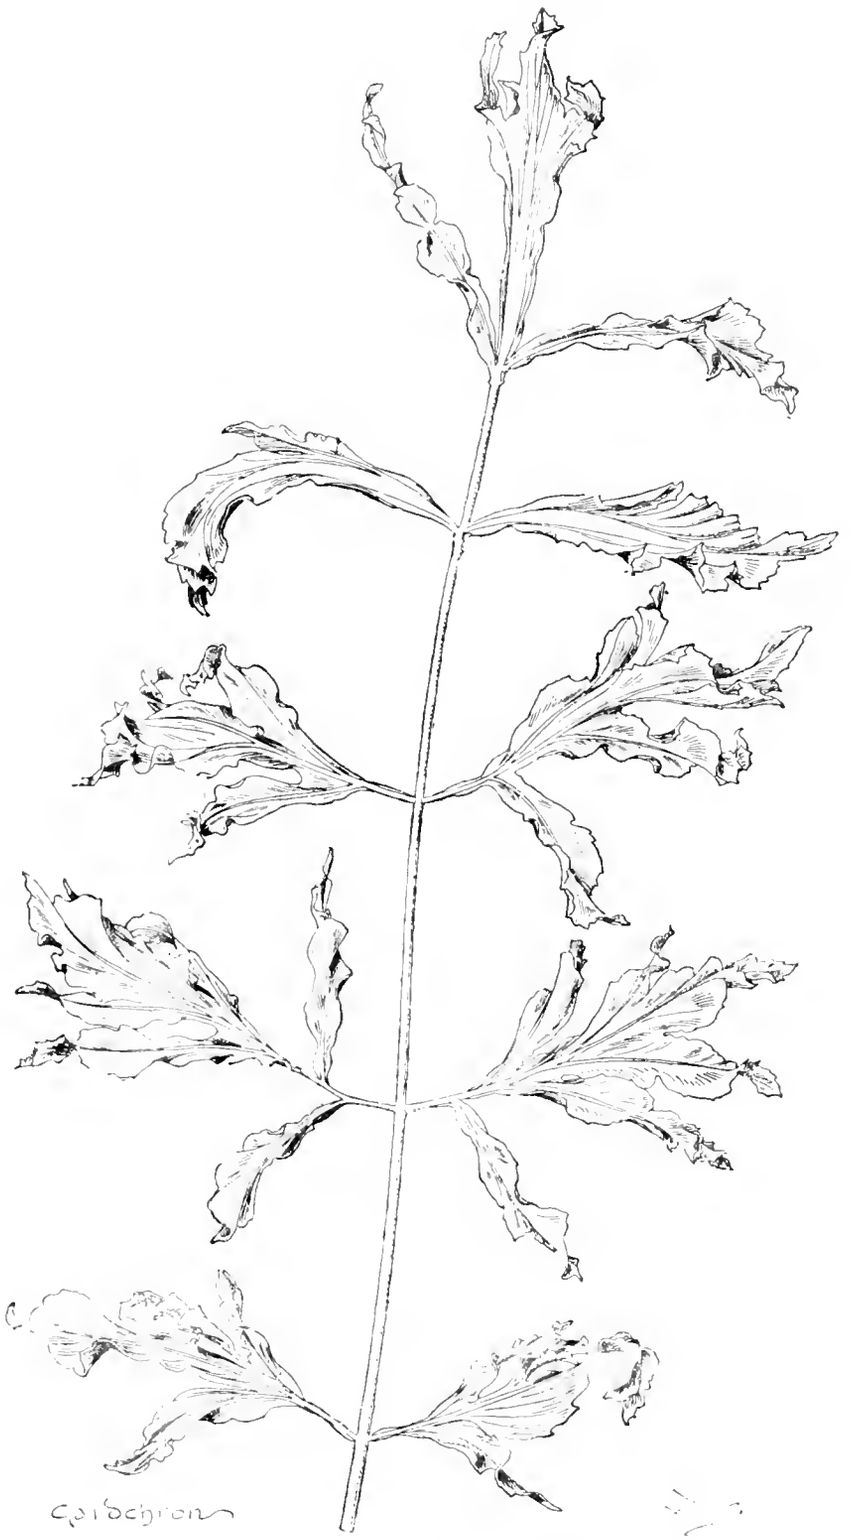

FIG. 65.—OSMUNDA PALUSTRIS VAR. MAYII.

THE ROSARY.

AUTUMN CULTURE OF ROSES.

OCTOBER will be a very busy month in the Rose garden. The planting and preparing of the ground by trenching for planting must then be undertaken. A fairly well drained loamy soil will meet the requirements of most varieties. Some well decayed farmyard manure and half-inch bones should be incorporated with the soil as the trenching proceeds, but these instructions will avail little unless we have, prior to planting, a heavy and continuous downpour of rain, for, in the south, the long drought has been much more serious than has been the case for some years. I am an advocate of early planting providing the soil is in anything like a suitable condition. The trenching should be done some weeks in advance of planting so that the ground may become settled. Briar and other stocks intended for budding can be planted early this year on account of the forward ripening of the wood. Seedling Briars and Briar cuttings succeed best on heavy land, the Manetti and the multiflora stocks on lighter soils. These can be planted any time after the second week in October, as circumstances permit. Standard Briars can be planted last of all, or even during November, but I will refer to these later.

A goodly portion of the pot Roses that have been plunged outside during the summer may be placed in October in a cold house or frame, in which plenty of ventilation is allowed both during the day and the night time, providing the weather be genial. These plants will furnish an abundance of bloom for some time to come, and the remaining plants if brought in later will provide a succession of bloom. A light spraying with the syringe on bright days when the trees are first brought in will help the buds to open, cleanse the growths and keep the foliage fresh. If the plants have rooted through the pots they should be placed on or be plunged a few inches deep in a bed of soil, but on no account should the roots be mutilated till the flowering season is over. On or about the 15th of the month is a suitable time at which to lift plants from the ground for potting for later forcing. They should be carefully taken up with all their fibrous roots intact, and be allowed to carry three or more well ripened shoots. Directions for potting and preparing of soil were given in a former paper. Hybrid Tea varieties will be found to succeed and flower well in pots with less forcing than varieties of the Hybrid Perpetual type. There are two varieties that I should like to mention. They are old kinds but they are still of the best quality, viz.: G. Nabonnand and Souvenir de Catherine Guillot. They have both handsome foliage and are profuse bloomers and their flowers open well, which is a very desirable quality, as some varieties fail to do this. When the potting is completed, they can be plunged for a month outside in a bed of ashes before being brought into the glass-house, for until they are established they must be kept cool, and forcing must be deferred until the plants have plenty of active roots. An important operation in October is the insertion of cuttings. Well ripened shoots should be taken for the purpose with or without a "heel," and the cuttings, from 6 to 8 inches in length, be planted in lines on a north aspect 6 to 9 inches apart. The soil should be prepared previous to planting, and some good gritty sand and burnt earth should be well incorporated with it. A portion of these materials can be put in with the cuttings when the trenches are made, for it will help the cuttings to form a callus. Tread the soil about the cuttings firmly, and leave two or three buds above the surface of the ground level. After all is finished, apply a thin mulch of cocoanut-fibre. *J. D. G.*

PLANT NOTE.

ASCLEPIAS DOUGLASI.

THIS perennial, a native of Western America, is little known in gardens, but is worthy of culture for its foliage alone. The entire leaves in strong specimens are a foot in length and 4½ inches in width, and the plant, exceeding 6 feet in height, has a noble appearance when it has attained its fullest dimensions. It flowers in August, producing numerous rounded heads of small blossoms, some of the flower-clusters having a circumference of 11 inches. When all the blooms are fully expanded these "flower balls" appear flesh-pink in colour. The corollas, which are less than half an inch across, are yellowish in tint and the reflexed petals of a dull reddish hue. The blossoms are perfumed, and the flower-heads attract innumerable Humble bees, which soon become stupefied by the nectar. Between 150 and 200 blooms are contained in a single flower-head. *S. W. F.*

The Week's Work.

FRUITS UNDER GLASS.

By T. W. BIRKINSHAW, Gardener to Lt.-Col. Sir CHAS. HAMILTON, Bart., Hatley Park, Bedfordshire.

Early Black Hamburghs.—If the vines that were forced early have made weak growths, it is a sign that they need attention at their roots. No better time than the present can be selected for overhauling the borders should they require it. Have some new compost prepared ready for applying as the work proceeds, but before commencing see that the old border is in a thoroughly moist condition and cover the glass-roof with mats, so that the foliage may be kept syringed without fear of burning. Commence by forking out the old sour soil, but do not damage or bruise any of the roots during the process. When sufficient of the old compost has been removed, make up the border again with the new soil, spreading all the roots evenly near to the surface before they are covered. Half-decayed leaf soil and grit should be placed about the roots, for these substances encourage the formation of new fibrous roots. Use the coarser material on the top and when finished make the border quite firm. Retain the shading on the roof for some time longer, and always keep the foliage moist. New roots will soon begin to spread in the compost, and by autumn the vines will have recovered from their disturbance, but they must not be started into growth early.

Young Vines of this season's planting should be watered carefully and they should also be kept free from red-spider and thrips. They will derive much benefit from a little artificial heat, at the same time ample ventilation should be given them. Gradually reduce their lateral growths each week.

Grape Gros Guillaume.—This variety does exceedingly well when grown in the same house as Muscats, and, with proper treatment and careful attention during its growing period, very large bunches of fruit may be had. This variety has a reputation for shyness in bearing, but this can be largely overcome by occasionally cutting out the old rods and training young ones in their places. It seems to succeed better when inarched on Buckland Sweetwater or Muscat of Alexandria, than when it is growing on its own roots. The fruit has quite a noble appearance on the dinner table, and it is well worthy a place in any vinery. In most cases the fruit will now be ripening, but with care it can be had in good condition until November. Liberal supplies of food are necessary in order that the bunches and the berries may become properly finished. The rods should be trained fully 4 feet apart to allow plenty of space for the strong growing foliage.

THE FLOWER GARDEN.

By HUGH A. PETTIGREW, Gardener to the Earl of PLYMOUTH, St. Fagan's Castle, Glamorganshire.

Naturalising Bulbs.—Where wild gardening is practised the present is an appropriate time for arranging for displays in the spring months. In the old Orchard that is retained because of its picturesque appearance, whose trees are preserved because of their green, lichen-covered trunks and bright ornamental fruits rather than for their economic value, many desirable effects may be had from bulbs. Natural, informal stretches of Snowdrops, Crocuses, Narcissi, and Tulips to succeed one another in flower, with here and there groups of blue Apennine Anemones, Chionodoxa Fritillarias, and Scilla sibirica, if tastefully arranged will create charming effects. To obtain the best results the bulbs must be used liberally for planting thickly in broad, rich masses of one kind. In grouping, the aim should be to avoid hard lines of demarcation between the colours and groups, and at the outskirts to let them disappear quietly and not abruptly into the space around. In undulating grass the ridges should be left unplanted and only the hollows filled in. To achieve a natural form of grouping one must, after having determined on the size and shape of the groups, throw the bulbs in large handfuls in the direction the effect is desired, and then let men follow with trowels or crowbars to plant them exactly where they have fallen. By doing this stiffness and formality will be avoided. Where the bulbs are to be grown, the grass should be mown quite closely previously to planting, in order to facilitate the operation, and again at the close of the growing season of the grass, so that in the spring the flowers can be seen to the best advantage. After the bulbs have flowered the grass must not be mown until the foliage has ripened, otherwise the vitality of the plants will be impaired and they will not flower well the following year. The bulbs should be put down as deeply as it is possible to put them, for no matter how deep they are planted the flowers will appear above ground at the proper time, and by being deeply planted they will be the safer from the attacks of mice. In naturalising Snowdrops, they should be grouped in the grass near to the pathways, while the white and yellow Crocuses are better seen at a distance in distinct clumps of colour. The purple coloured Crocus is the least effective in grass, and should only be grown in spots open to the full sunlight. Of Narcissi suitable for naturalising the kinds are numerous, but the following are amongst the best —*Large Trumpets:* Emperor, Empress, Golden Spur, Henry Irving, Horsfieldii and Obvallaris. *Medium Crowned:* Barri conspicuus, Leedsii, Sir Watkin and Stella Superba. *Small Crowned:* Burbidgei, Poeticus and Duchess of Westminster. Duchess of Westminster is rather expensive, but it affords a lovely effect in grass. Queen of Spain is a charming Daffodil that should have a favoured spot given it, close to a walk through the grass, as it is a delightful flower and really does better naturalised than cultured in a border. Tulips, unlike the Daffodils and other bulbs mentioned, unfortunately do not increase when naturalised, but require to be replanted every three years. Cramoisie Brilliante and Dusart are two varieties well adapted for the grass as their colours show up well at a distance, and they are of such sturdy habit that they hold their flowers erect in their surroundings.

THE KITCHEN GARDEN.

By J. GIBSON, Gardener to His Grace the Duke of PORTLAND, Welbeck Abbey, Notts.

Autumn trenching.—At this season of the year, when many crops are being cleared from the land and it is too late to plant others, the opportunity should, whenever possible, be taken to trench the ground, with a view to securing an early crop next spring. The surface of the soil is generally trodden hard in the gathering of such crops as Peas, Beans, Onions, &c., but it is not advisable that it should remain in a solid condition all through the autumn and winter. The disintegration of the soil by the agency of atmospheric gases and of water is retarded when the soil is in a solid condition. Therefore it is advisable to trench early and manure the ground in a suitable form for the crop that is intended to be planted in spring time. Now is the best time at which to prepare for next year's Onion crop, and by early manuring the material has time to become well rooted and incorporated with the soil, so that it is in the best condition when the young roots are ready to absorb it. Soils of a light texture may, in trenching, have the second and the bottom spits brought to the surface, but if the subsoil is very heavy and clayey, thoroughly break up the bottom of the trench and add plenty of material that will lighten its texture, such as road-sweepings, wood ashes, &c., and allow it to remain until the next time of trenching before being brought to the surface. Ridging heavy soils is strongly to be recommended in order that the influences of frost and air may pulverise it and bring it into a better working condition. The value of deep culture of the soil has been especially evident during the past season. I may instance a crop of Peas that were sown on a

well-trenched quarter of land and close by were several rows that were sown on land that had not been trenched for some years. The difference in height of the haulm of the same varieties on the two pieces of ground was nearly 2 feet, and the amount of Peas gathered from the trenched ground was nearly double that of the other, besides lasting much longer in bearing. This demonstrates that it is far better and more profitable to cultivate a limited space really well than a large area indifferently.

Turnips.—The recent rains have caused the seeds of autumn-sown Turnips to germinate well. Before the seedlings become too large they should be thinned to about 9 inches apart in the rows. It is a mistake to delay thinning, as leggy seedlings never form satisfactory roots. Afford the plants plenty of water in dry weather, otherwise there will not be time to mature the crop before the hard weather arrives. Early crops that have reached their full size should be pulled up and the roots be laid in a shady border in moist soil, so that they may retain their best qualities.

Beet.—Many roots of this vegetable have now reached their full size, and if they are left longer in the ground loss of colour and quality will result. It will be quite safe to go over the crop and pull all that are in condition and "heel" them in a shady spot with their rootlets and leaves intact, until the general crop is ready for storing, when they can all be stored together. I have never known this early-lifting to injure the quality of the roots when the work has been done, as it should be, in a careful manner.

Winter Vegetables.—Keep the ground about these crops clear of weeds, and well stir the soil between the rows to encourage the best possible growth. Any blank spaces may still be filled, but the plants must be transplanted with good "balls," for this is essential at this late date.

THE HARDY FRUIT GARDEN.

By W. A. COOK, Gardener to Sir EDMUND G. LODER, Bart., Leonardslee, Sussex.

Peaches and Nectarines.—These fruits should be gathered as soon as they will part readily from the tree, for if they are allowed to remain until they are over-ripe they will not keep in good condition long. It is also a mistake to allow the fruits to tumble off into nets, for they are worthless the second day after falling owing to bruises and marks. That excellent variety Grosse Mignonne is generally at its best after the first week of September, and is followed by Bellegarde in order of ripening. Princess of Wales and Sea Eagle should receive copious supplies of liquid and heavy syringings to enable them to finish up their fruits. The leaves should be drawn away from the fruits to allow the sun's rays to reach them. If red spider has been kept under it will not be troublesome after this date. All trees from which the fruits have been gathered should receive attention in the matters of watering and syringing in order to keep them in good condition. Trees that have been condemned should be rooted up, and the ground be prepared for the reception of other trees. Early varieties that have almost ripened their wood can be transplanted now if desired, especially if the trees have been prepared for shifting by trenching around their roots. When lifting it is necessary to unfasten the branches so that the tree can be lifted entirely. After transplanting it will be necessary, should bright sunshine prevail, to hang a mat or some other shading material in front of the tree for about a week or ten days in order to prevent the leaves from flagging. The foliage should be syringed twice daily.

Pears now ripening should be watched, or they will soon be over-ripe and useless. Early varieties should be gathered as soon as they will part readily from the tree. Williams' Bon Chretien is always of better flavour when the fruits are gathered before becoming dead ripe. Clapps' Favourite is a Pear of good appearance and of very fair quality. This variety should be sent to table soon after gathering. Jargonelle is best ripened a few at a time, for this delicious Pear will not keep in good condition long. The best examples of this Pear are those grown on walls, and preferably upon fan-trained trees. Marguerite Marillat is a handsome fruit, and requires good cultivation to bring it to perfection. It is large, juicy, and sweet, and one of the best of its season. All cordon-trained trees would derive benefit from good soakings of water and applications of liquid manure. Keep the laterals away from the fruits of later varieties to allow the sunshine to reach the latter and promote flavour and colour.

Apples.—These fruits should be gathered and stored as soon as they are ready. Wasps are attacking the early fruits to a great extent. Apples, I fear, will be small this season on account of the large crops and the dry weather. Beauty of Bath, Irish Peach, Quarrenden, Lady Sudeley, and Red Astrachan are all ripening.

Culinary Apples.—The trees should receive water if they are suffering from drought, or the fruits will be of inferior quality. Early varieties such as Lord Grosvenor, Lord Suffield, Frogmore, and Domino should be gathered and used as soon as ready. Gather them carefully and store in the fruit room, which should be kept cool and well ventilated.

Strawberries.—The fruits of Alpine varieties must be protected from birds and wasps, and this is best accomplished by means of wasp-proof netting or gauze. Water young plants thoroughly in order to keep them growing and to protect them from attacks of red spider.

Strawberry plants for forcing should be potted by this date, and placed in full sunshine on a hard bottom—preferably ashes—and stood in batches conveniently arranged for watering. These will be improved by occasional syringings on bright afternoons. Keep the soil free from weeds and the plants free from runners.

Figs.—If wasps are at all troublesome, place the fruits in small muslin bags. On south walls it will be necessary to give the trees a good soaking of water.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower to Sir TREVOR LAWRENCE, Bart., Burford, Surrey.

Masdevallias.—The month of September is a suitable time at which to re-pot or replace the surface material of the receptacles in which these plants are growing, but if more convenient these operations may be delayed until February. I usually attend to these matters at the present time, because during the next two months the plants make the greater number of their new roots, and, further, the cool, moist air during the autumn is favourable to their recovery after disturbance. Strong healthy specimens may need additional rooting space, but if they are intended for exhibition next spring they should not be unnecessarily disturbed now, for they might then fail to bloom satisfactorily when required. If a plant has overgrown its receptacle, the pot or pan should be carefully broken, and the plant be placed into another of suitable size without the least disturbance of the roots. Extra large plants which have lost their centre leaves may be divided and made up anew, or they may be made up into several neat, compact specimens. A few days previous to re-potting it is advisable to allow the plants to become moderately dry, for the drier the roots are the less liable are they to receive injury. All Masdevallias of the M. coccinea or Harryana section, M. Veitchiana, M. Lindeni, M. ignea, M. macrura, M. peristeria, M. coriacea, M. ephippium, M. Gargantua, M. elephanticeps, &c., are of robust growth, and are vigorous rooting plants; consequently they require plenty of space in which their roots may ramify. Dwarf, compact-growing varieties as M. Estradæ, M. caudata Shuttleworthii, M. Wageneriana, M. ionocharis, M. hieroglyphica, M. picturata, M. O'Brieniana, M. tridactylites, M. muscosa, M. xipheres, &c., succeed best in as small a receptacle as they can conveniently be placed. The same remarks are applicable respectively to hybrids which have been raised from either section. Masdevallias require plenty of drainage in their pots, and should have them filled two-thirds with crocks or well-dried pieces of Fern rhizome, and over this should be placed a thin layer of rough sphagnum-moss. When re-potting keep the base of the leaves on a level with the rim of the pot, and for a compost use fibrous peat and sphagnum-moss in equal proportions, mixing with it a suitable quantity of broken crocks and some coarse silversand. Make the compost moderately firm about the roots, especially around the centres of the plants, but do not ram the potting medium to such an extent that water cannot pass freely away, or the soil will soon become sour. Water should, for several weeks, be afforded very carefully, for excess of moisture during that time would cause the loss of many leaves and roots. When new roots are seen pushing through the soil, the supply of water should be gradually increased. A slight spraying overhead on bright days will help the plants considerably, but it must not be afforded in sufficient quantity that it runs down the leaves into the compost. When no separate house is available for these plants, a suitable position can easily be found them among the cool Odontoglossums.

Heating System.—Everything connected with the heating apparatus should be overhauled annually, and the present is a suitable time to do this overhauling. Ascertain if everything is in good working order, so that during the coming winter the proper temperatures may be maintained without difficulty. When cleaning out the boilers, hot water pipes, &c., it is advisable to make use of all the sun-heat to maintain the necessary temperatures in the warmer divisions. While the work is being undertaken use less water when damping the houses, and afford smaller quantities of water to the roots, it being safer to keep them somewhat dry than too wet. The work will not affect the plants in the cooler divisions if it be done at once.

PLANTS UNDER GLASS.

By B. CROMWELL, Gardener to T. SUTTON TIMMIS, Esq., Cleveley, Allerton, Liverpool.

Violets.—These should now be lifted from the open ground and be transplanted into pits or frames. The border should, if at all dry, receive a soaking of water the day before they are taken up, so that much soil may adhere to the roots. In planting, pack them close together, in order to get as many plants in the frame as is possible. Place them within about 6 inches of the glass, for the more light they receive the better will be the colour and substance of the flowers. Immediately after planting they should receive a good watering in order to settle the soil about their roots, after which the lights should be placed on the frames and the plants be kept shaded until they have recovered from the effects of moving. When established, and providing the weather continues warm, the lights may be left off the frame both during the day and night time, and this condition may be maintained until frost makes its appearance. A syringing at intervals of a few weeks with clear soot water will be a safeguard against an attack of red spider.

Housing Plants.—Preparations should be made for the housing of hard-wooded plants, that undue exposure to heavy rains which will cause an excess of water at the roots may be avoided. Ericas and Azaleas are amongst the first subjects to suffer from a superabundance of water at their roots, and especially does this apply to plants newly potted. After returning the plants indoors do not fail to give an abundance of ventilation both during the night and the day, for this will mature the wood and harden up the flower buds which, in Azaleas, are now becoming plump. Should the weather continue warm throughout the present month afford a gentle syringing overhead once a day, as this will be equivalent to the night dews which the plants have been subjected to outside. Keep a sharp look out for the small white scale insect on Acacias. These pests can be eradicated by spraying the plants with XL insecticide. Previous to bringing the plants indoors the interior of the houses should be thoroughly syringed with a mixture of soft soap and a wineglassful of insecticide in four gallons of water. This will clear the woodwork and the walls of red spider and other insects which have established themselves in the crevices. The dry, arid conditions in the plant houses during hot weather favours the increase of these pests which, if left undisturbed, will prove very troublesome in the early months of the new year. The drainage in the pots of all plants that have been standing outside should be examined, and if found defective be at once made perfect.

Bulbs for forcing.—The first batches of these should now be planted. If very early flowers are desired it is much better to plant the bulbs early than to subject them to hard forcing, which, in many cases, causes the flowers to go "blind." Flowers from plants that have not been forced too quickly will have more substance, and will also last much longer when cut. If grown specially for producing flowers for cutting, the best receptacles are boxes about 6 inches deep, but if they are needed as plants for decorative purposes pots are better for the purpose.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication *as well as specimens and plants for naming, should be addressed to the* **EDITOR, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Special Notice to Correspondents.—*The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.*

Illustrations.—*The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c., but he cannot be responsible for loss or injury.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.*

Local News.—*Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

APPOINTMENTS FOR SEPTEMBER.

SATURDAY,	Sept. 1	Soc. Franc d'Hort. de Londres meet. / German Gard Society meets.
TUESDAY,	Sept. 4	Nat. Amateur Gard. Assoc. meet.
WEDNESDAY,	Sept. 5	Glasgow and West of Scotland Hort. Soc. Show. / Westcott Dahlia Show.
THURSDAY,	Sept. 6	Nat. Dahlia Soc. Exh. at Crystal Palace.
FRIDAY,	Sept. 7	Manchester and N. of Eng. Orchid Soc. Exhib. in Manchester Botanic Gardens.
SATURDAY,	Sept. 8	Dutch Gardeners' Soc. meet at Richmond.
MONDAY,	Sept. 10	United Hort. Ben. & Prov. Soc. Com. meets.
TUESDAY,	Sept. 11	Roy. Hort. Soc. Comms. meet.
WEDNESDAY,	Sept. 12	Roy. Caledonian Hort. Soc. Show in Waverley Market, Edinburgh (2 days). / Meeting of British Gardeners' Association at Edinburgh.
THURSDAY,	Sept. 13	York Dahlia show (2 days).
SATURDAY,	Sept. 15	German Gard. Soc. meets.
MONDAY,	Sept. 17	Nat. Chrys. Soc. Com. meets at Essex Hall, Strand (3 p.m.).
TUESDAY,	Sept. 18	London Dahlia Union Exhib., Regent's Park (2 days).
WEDNESDAY,	Sept. 19	Nat. Rose Soc. Autumn Exhib. at Roy. Hort. Hall, Westminster.
THURSDAY,	Sept. 20	Evening Nat. Chrys. Exhib. at Hort. Hall, Westminster.
TUESDAY,	Sept. 25	Roy. Hort. Soc. Comms. meet.
SATURDAY,	Sept. 29	Michaelmas Quarter Day. / Dutch Gardeners' Soc. meet.

AVERAGE TEMPERATURE for the ensuing week, deduced from observations of Forty three Years at Chiswick: 60·6°.

ACTUAL TEMPERATURES:—

LONDON.—*Wednesday, August* 29 (6 P.M.): Max. 75°, Min. 52°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—*Thursday, August* 30 (10 A.M.): Bar., 30·3, Temp., 68°, Weather—Fine.

PROVINCES.—*Wednesday, August* 29 (6 P.M.): Max. 71° Bury St. Edmunds, Min. 61° Scotland north-east.

SALES.

MONDAY AND WEDNESDAY—Bulbs at Stevens' Rooms, King Street, Covent Garden, at 12.30.

MONDAY, TUESDAY, WEDNESDAY, THURSDAY, FRIDAY, — Dutch Bulbs in large variety at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 10.30.

Two Leaders in Science.

It is with no ordinary feeling of regret that we have to announce the death on the 20th ult. at Torquay, of Dr. Marshall Ward, in his 52nd year. Since 1895 he had acted as Professor of Botany in the University of Cambridge, having previously acted in that capacity at Coopers' Hill. This is no place wherein to do more than allude to his original researches, as brilliant as they were solid, into the history and nature of bacterial and other fungal diseases—researches which won for him the "Royal Medal" from the Royal Society. We are more concerned here with his labours in applied science. Marshall Ward was indeed pre-eminent among modern botanists, who have known how to turn to practical account the researches of modern science. His services to the Coffee planters of Ceylon, in the matter of the Hemileia are well-known to those interested in tropical cultures. To home cultivators he is known by his numerous treatises on disease in plants generally, and in timber trees in particular, and among his latest publications are those on Grasses and on Trees, the latter intended to supply students of forest-botany with a guide to the study of trees and shrubs from the point of view of the out-door naturalist, at the same time to interest them in methods of laboratory work, and in those biological researches too much neglected in former days, but which now, by the sway of the pendulum in the opposite direction, interfere too greatly with the study of plants in the field, and with those details of structure and classification which are so essential to medical students, to cultivators, and to all who have to apply a knowledge of botany to every-day use. Marshall Ward, however, seemed always to have in mind the requirements of the practical man. An illustration of this occurs to us as we write. The Professor had been lecturing in the great vinery at Chiswick on the diseases of timber trees. Among his auditory were a number of students from one of our colleges, and, after the Professor's lucid and thorough explanations, the comment was made in our hearing—"How different this is from the 'gardeners' gas' we so frequently experience." The allusion had reference to certain county council lectures given by teachers imperfectly equipped for their task. A further illustration may be found in the Professor's recent inaugural address to the students at Wye College, which is alluded to in another column. Indeed, while no research seemed too recondite or too abstruse for him, no detail which was or might be of practical importance was overlooked by him.

Marshall Ward was a member of the Scientific Committee of the R.H.S., and his contributions to the journal of the society are, if not numerous, at least among the most valuable of the many that have appeared in late years. His loss will be severely felt not only in Cambridge but wherever botanical science is pursued.

The news of the death, on the 25th ult., of CHARLES BARON CLARKE will be read with the greatest concern by his numerous friends and associates. Mr. CLARKE graduated M.A. at Cambridge, and was for many years in the civil service of India. He travelled widely in the north-west districts of that country, where he collected largely. He acted for some years as Director of the Royal Botanic Gardens in Calcutta, and on his return to England established himself at Kew and devoted himself to systematic botany, writing numerous monographs and contributing to various "Floras." He was a Fellow of the Royal Society, and was for some time President of the Linnean Society. Although specially devoting himself to systematic botany, Mr. CLARKE was a singularly well-informed man, versed in classics, mathematics, music, farming, and we know not what besides. His knowledge of the geography and natural history of India was profound. His willingness to assist his fellow-workers was proverbial, and, like many others, we have often had occasion to avail ourselves of his vast and varied stores of learning, and to profit by his critical judgment on points of doubt and difficulty. He was probably little known by the general public, but his merits were keenly appreciated by his fellow-workers, and the void left in the ranks of botanists by his decease will indeed be difficult to fill. Mr. CLARKE, who was unmarried, died in consequence of inflammation set up or accelerated by a long cycle ride.

The Royal Botanic.

The remarks we made in a recent issue on the subject of this Society have elicited the following letter from a very old correspondent of this journal. The statements he makes do not, in essence, differ very widely from those we made, but in any case in deference to one who we know has the interests of the Society at heart we now insert his communication without any further comment of our own:—

"In your remarks on the present condition of the Royal Botanic Society you are a little in error. Certainly the gardens ought not to have been called botanic, as they have never received any encouragement from the Government to pursue scientific botany, have no Government grant, and have only been indebted to the Government for increased rent and the obligation to open the gardens twice a week to the public. It is really since the exclusive policy was abandoned that the Fellows have, to a certain degree, fallen off. Now it is extremely easy on any day to get an order to enter. Monday, Wednesday, and Saturday are public days. During this summer 70,000 people have been admitted at really nominal payment. The gardens were originally formed as a 'rus in urbe'—a garden in the midst of London, with as much of wild nature as is possible maintained. And to keep up this character the Council are striving. The great use of a garden of this character is to show what plants and trees will grow in London naturally and simply. The Botanical Gardens are for this purpose very remarkable, and the Economic House, as well as the Victoria House, show many plants not generally seen; but these parts are generally utterly neglected by the visitors. There is also a school of gardening, and a ladies' class, with a kitchen garden, that surprises me by its success. The report of the leading gardeners, whom we asked to visit the gardens, will tell you of the excellent condition of the stock. But a garden of this character is of little pleasure to those living a long way off. It must be principally supported by persons living near, who want a place of quiet recreation. It is a bad place for sales, and, naturally, leading nurserymen prefer Vincent Square. I agree with you that the Society has relied too much on garden parties, &c.; but this is an important source of revenue. The real difficulty is the success of a minority, who call themselves a reform committee, to prevent the raising of the subscription. If this had been granted, as the majority accepted, our position would be now without difficulty. We are quite unable to keep up or pay the gardeners properly with the present income, and have to cut down many suggestions of our head gardener, Hawes, than whom there is no more capable London gardening superintendent.

The principal 'debt' is the debentures, which are only troublesome when the executors of deceased owners require immediate payment. The Horticultural Society suffered from this, and annulled their own; at least, I lost mine without any compensation. We proposed, with an increased subscription, to create a sinking fund to meet this. The 'reformers,' in reality, seem to wish to wreck the Society as it is, and turn it to some other purpose, destroying one of the most remarkable bits of natural scenery any town possesses. They laugh at a place for 'rest and meditation.'" *C. Brinsley Marlay, St. Katharine's Lodge, Regent's Park, August 31.*

OUR SUPPLEMENTARY ILLUSTRATION (CAMPANULA LACINIATA).—The "fairest Campanula in all Greece" is the description given of this plant by TOURNEFORT, who found it on the rocky island of Pholegandros, in the Grecian Archipelago, in the year 1700. It is figured in his *Voyage in the Levant*, and he there describes the plant as growing two feet high, forming a round, compact bush, with basal leaves (see fig. 66) 8 inches long by 2½ inches broad, deeply laciniate, and light, shining green in colour. The cauline leaves are smaller, being 2 to 3 inches long, diminishing in size on the upper part of the stem, which is woody, and as thick as a man's thumb, much branched, and laden with flowers at the extremities of the branches. The bell-shaped flowers are about 2 inches wide at the mouth, rather over 1 inch deep, and pale blue in colour. C. laciniata belongs to a section of this popular genus, which is composed exclusively of biennials, and includes C. lyrata, C. lanata, and C. tomentosa. It is said to have been introduced into British gardens in the year 1790, but the figure under this name in ANDREW'S *Botanist's Repository, VI.*, f. 385, published in 1804, represents Campanula tomentosa, as does also the figure of C. laciniata in NICHOLSON'S *Dictionary of Gardening*. In habit and in the shape of its flowers, as well as colour, this plant approaches the Caucasian C. mirabilis, but is more robust and erect, as well as being slightly pubescent all over the stems and leaves. C. laciniata is probably only hardy in the more southern and warmer parts of this country, and being a biennial, seeds will have to be relied upon as the means of propagation. For the specimen from which our illustration was taken we are indebted to Mr. BEAMISH, of Cork.

THE SHREWSBURY SHOW.—The receipts at the recent show of the Shropshire Horticultural Society, of which a full report was published in our last issue, were as follow:—*Cheap tickets sold before the Show took place*, £552, against £539 18s. 2d. in 1905; *receipts at the gates*, first day, £1,107 3s. 8d., against £813 7s. 4d. in 1905; second day, £2,210 7s. 3d., against £2,229 18s. 3d.; *total*, £3,869 10s. 11d., as against £3,583 3s. 9d. last year, being an increase of £286 7s. 2d. These particulars refer only to receipts at the gates and for purchased tickets, and do not include the value of tickets issued to subscribers, whose subscriptions amount to over £500, and for which subscribers are entitled to eight tickets for every guinea subscribed and four tickets for every half-guinea. By a misprint in our report last week, the sum given by Messrs. SUTTON & SONS as prizes for vegetables was stated to be £8 17s., instead of £17.

SCIENTIFIC COMMITTEE.—We are requested to announce that there will be no meeting of this Committee on September 11, but that the meetings will be resumed on September 25.

"EVENING NEWS" CHRYSANTHEMUM LEAGUE.—The following extracts from a letter addressed to us by the Secretary will be read with interest by lovers of the Chrysanthemum:—"May I ask you to bring under the notice of your readers the forthcoming show of the *Evening News* Chrysanthemum League, which is to be held at the R.H.S. Hall, Vincent Square, on September 20, 21, and 22? Our Committee and Judges include Mr. T. BEVAN, Chairman N.C.S., Mr. WITTY, Vice-Chairman N.C.S., Mr. D. B. CRANE, Chairman Floral Committee N.C.S., and the following Fellows of the R.H.S.:—W. A. CULL, W. HARRISON, R. F. FELTON, H. EVANS, D. INGAMELLS, C. H. CURTIS, G. WOODSTOCK, E. F. HAWES, and F. W. JONES. Last year we held our first show, when many thousands of visitors failed to get admission. We shall be offering gold, silver-gilt, silver, and bronze medals for the most meritorious trade exhibits, besides nearly 200 other prizes to members of the League who show their plants. Special instructions are given to the League members from time to time in the *Evening News* which assist them in the cultivation and keep their interest in the Chrysanthemums. Trade exhibits promise to be large in number, and a special section of the Hall will be given up to horticultural sundries. Early notification of intention to exhibit will be necessary, as there is already a marked desire on the part of professional growers to be represented, and the space reserved is very limited. There is also a limited amount of wall space, suitable for business announcements, &c., still unallotted. The success of this year's show is already assured, for in June nearly 7,000 plants,

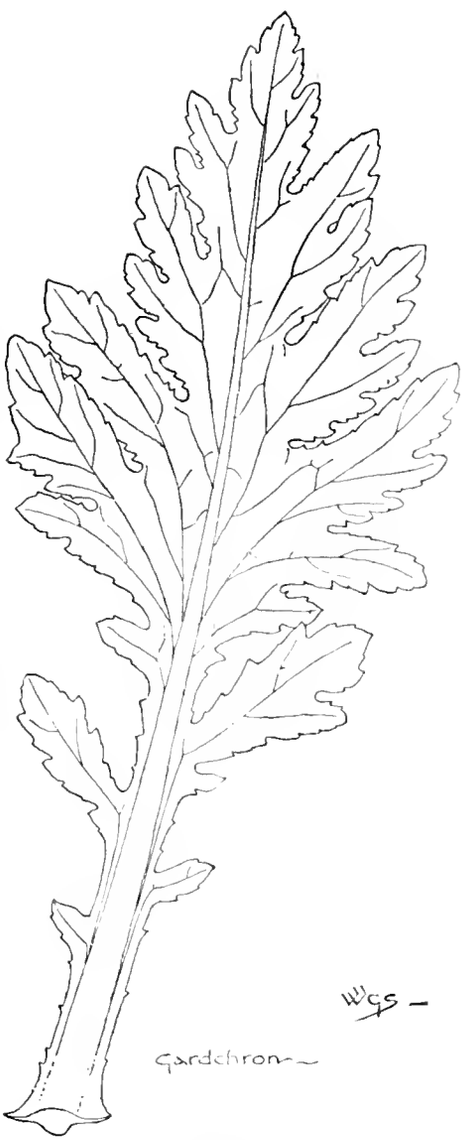

FIG. 66.—LEAF OF CAMPANULA LACINIATA (REDUCED).

(See page 165 and Supplementary Illustration.)

in 37 decorative Japanese varieties and 16 varieties of pompones, were applied for by members of the Chrysanthemum League, and, judging by the letters already to hand, &c., a very large number of members will compete for the many prizes offered. All communications on the subject should be addressed to the Secretary, *Evening News* Chrysanthemum League, Carmelite House, E.C.

THE NATIONAL DAHLIA SHOW, we may remind our readers, will be held on Thursday and Friday next, September 6 & 7, at the Crystal Palace. Mr. BROUSSON, the hon. secretary, informs us that it is expected the show will be a very good one.

BRITISH GARDENERS' ASSOCIATION.—The Right Hon. the Earl of PLYMOUTH has consented to become President of the British Gardeners' Association. From the first his lordship has expressed sympathy with its aims and objects. He is a large employer of professional gardeners, and owns the fine old Castle of St. Fagans, near Cardiff, as well as Hewell Grange, in Worcestershire, &c.

—— MEETING AT EDINBURGH.—On the occasion of the Royal Caledonian Horticultural Society's forthcoming Show at Edinburgh an address on the British Gardeners' Association will be given by the Hon. Secretary, Mr. J. WEATHERS. The meeting will be held in the Bible Society's rooms, 5, St. Andrew's Square, Edinburgh, on Wednesday, September 12, at 7 p.m. The chair will be taken by Mr. J. W. MCHATTIE, city gardener, and it is hoped that all gardeners present in Edinburgh at the time will make an effort to be present.

WYE COLLEGE.—We have before us the July number of the *Journal* of the South Eastern Agricultural College as Wye, Kent, which is an interesting production as showing the determined efforts that are now being made to shake off that stagnation in the application of scientific method to cultural proceedings which in former years we have had so deeply to deplore. Wye is taking a high place in the education of agriculturists, the number of pupils is increasing (there are now over a hundred), and former students in all parts of the world are creating a reputation for themselves and for their college. A Council of Agricultural Research which will concern itself solely with original research into matters bearing on agricultural and rural economy is proposed, and no doubt Wye College and its staff are particularly well adapted to carry out such proposals. The appointment of Mr. E. G. SALMON for the purpose of carrying on research into the nature and history of the fungous pests attacking cultivated plants is a matter for deep satisfaction. The work of such an expert can but be beneficial to the students, the neighbouring farmers, and to science generally. Details are given in the Report concerning the practical operations on the farm and the insects and other animal pests injurious to the cultivator. In this section Mr. THEOBALD states with reference to the Currant bud-mite that there is nothing satisfactory to report, but that the variety known as Boskoop Giant seems to resist attack more than any other variety, owing to its strong growth. Red and White Currants growing between the Black were found to be attacked with mite, especially the white variety. The remaining notes on insects, by Mr. THEOBALD, are too numerous to allude to at length, but they are of great interest and value to the cultivator. The whole report, indeed, is full of useful information and valuable suggestions. We can only find space in conclusion to direct attention to the inaugural address of Prof. MARSHALL WARD on the relations between botany and agriculture. This lecture should be read in connection with the latter part of Prof. F. W. OLIVER'S address to the British Association at York, from which we hope to give extracts later on.

THE HOME LIBRARY.—We have received from Messrs. WM. COLLINS, SONS & Co., Herriot Hill Works, Glasgow, four volumes of their "Home" library. Here we have, for the sum of one shilling each, such classics as "Kenilworth," "The Cloister and the Hearth," "Pickwick Papers," and "Scottish Chiefs." Each volume is clearly printed, illustrated, and neatly bound in red cloth. Other popular books will from time to time be added to the series, leaving less excuse than ever for neglect of standard tales and novels. To brighten a long journey or any other tedious time the fare here offered is as cheap and far more wholesome than some of the modern rubbish so freely offered for this same purpose.

BOTANICAL CONFERENCE IN PARIS.—The *Revue Horticole* announces that the International Association of Botanists has organised an international conference to forward the progress of horticulture and agriculture by the selection, introduction, and distribution of every kind of useful plant. The object of the scheme is to increase the knowledge of such useful plants as the members of the association in all parts of the world can collect (fruit, seed, cuttings, or young plants) for cultivation, when distributed to members interested in them and in other countries. Further, a certain number of centres will be selected where chosen species can be cultivated experimentally for some years, with a view to selection and propagation. It is also intended to obtain, from botanical excursions and from travellers and explorers, communications concerning economic plants unknown or not widely spread in the districts visited, so that these plants may be kept under observation with a view to making practical use of them. To assist in carrying out this programme an international conference of members was summoned on August 25, at the rooms of the Société Nationale d'Horticulture, to promote the establishment of a section especially organised to define the objects to be obtained and the best methods of proceeding. M. PHILIPPE DE VILMORIN was the organiser of the conference, and many experts and directors of botanic gardens have promised to collaborate.

PELARGONIUMS IN PARLIAMENT SQUARE.—The deplorable condition of the Pelargoniums which were wont to be such a feature in association with the noble architectural detail surrounding them has been the subject of comment in the daily Press. Some attribute the disaster to the noxious fumes from the wood paving laid as long ago as last November; others lay the blame on the poisonous vapours exhaled by motorcars and motor omnibuses. Meantime, so far as we know, no one has taken the trouble to verify either conjecture, and yet the Scientific Committee of the R.H.S. meets within a few hundred yards of the spot, and there are plenty of experts available whose opinion would be of value.

SOLANUM COMMERSONI.—We have received the following communication from M. LABERGERIE:—"I have had my attention called to a report (étude) in the *Gardeners' Chronicle* upon Solanum Commersoni, and more especially upon Solanum Commersoni 'Violet.' It results from the investigations made that there is apparently complete identity of this variety with that known as Blue Giant. I am therefore sending you a pamphlet including different communications upon the subject made to French scientific societies, and which indicate a considerable number of differences, proving the 'absolute authenticity' of the variations of Solanum Commersoni." The report alluded to contains an account of a visit of inspection made by various members of the Scientific Committee to the trial grounds of Messrs. Sutton, near Reading. Since then comparative investigations have been made of specimens derived from the same source, including microscopical analyses of the pollen and other features, and if the conclusions arrived at are different from those of some of our French *confreres* they are in conformity with those of other botanists and cultivators of that country.

Publications Received.—*Reports on the Botanic Station and Experiment Plots, Montserrat*, 1905-6. Several improvements have been effected in the arrangement of the station, and a number of interesting plants were added to the collection. The progress of the cotton industry was rapid and successful. Mr. W. R. Buttenshaw submits the report in the absence of Sir Daniel Morris.—*Journal of the Agricultural and Horticultural Society of India*, 1905. Contains a notice of articles sent out from, and received by the society, and brief notes on subjects of interest to local growers.

CYPRIPEDIUM × HARRI-LEEANUM, PARK LODGE VARIETY.

THIS hybrid (fig. 67), for which E. Roberts, Esq., Park Lodge, Eltham (gr. Mr. W. Carr), received an Award of Merit at the meeting of the Royal Horticultural Society on August 14, represents one of the finest of the dark-coloured Cypripediums.

It was obtained by crossing C. × Harrisianum superbum and a fine form of C. × Leeanum, and the combination gives yet another instance of the value of second crossing.

CUPRESSUS NOOTKATENSIS.

I SEND a photograph (see fig. 68) of a drooping form of Cupressus nootkatensis which I found in a clearing of the forest, about a month ago. The plant is 5 feet 9 inches high, and, I think, if it grows its branches will turn out to be falcate. I have never seen anything handsomer or better adapted in its way for decorative purposes. *G. W. F., British Columbia, June 11.* [The pendulous variety is not unknown in our nurseries and is included in the *Kew Hand-List* of Coniferæ as in cultivation in that establishment.—ED.]

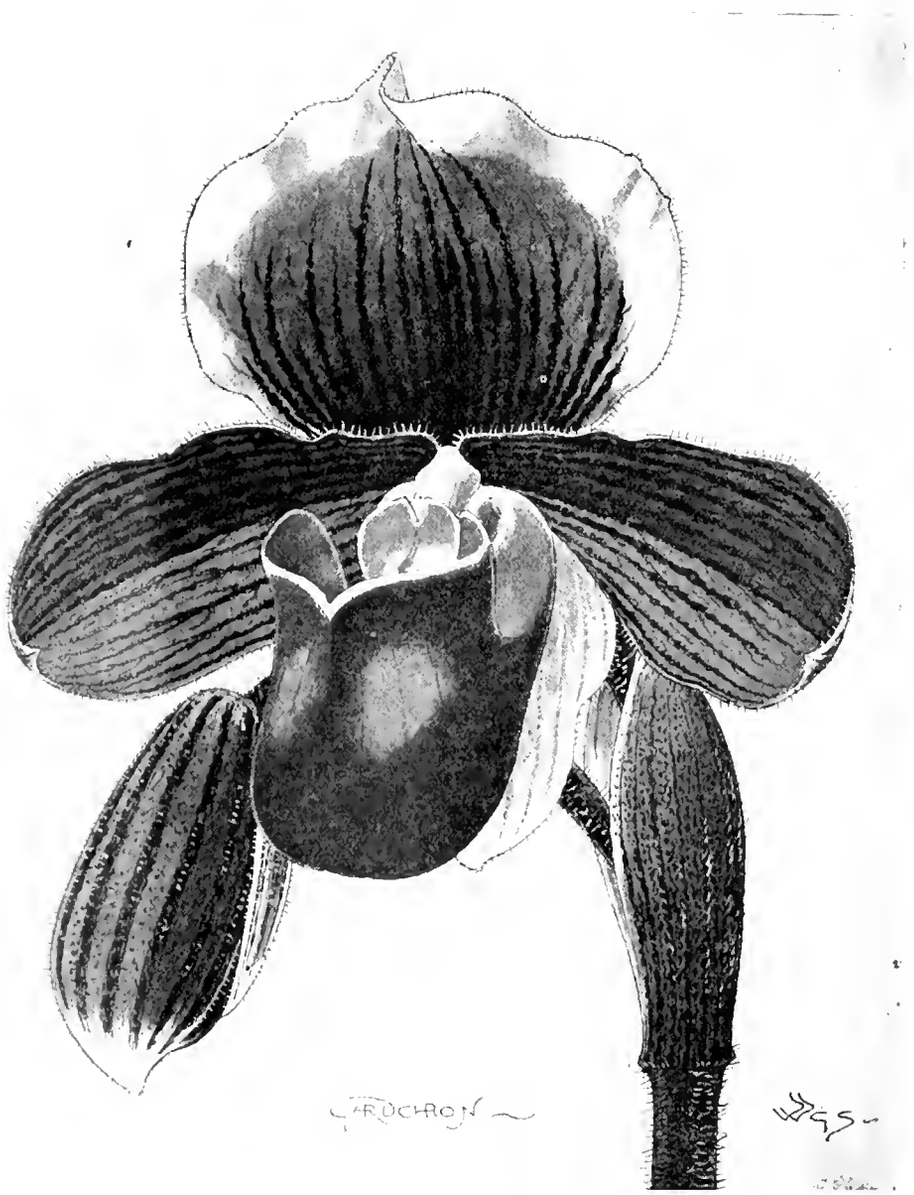

FIG. 67.—CYPRIPEDIUM × HARRI-LEEANUM, PARK LODGE VARIETY.

The habit of the plant resembles that of C. Harrisianum superbum, the leaves being pale green with dark green reticulation. The scape, which is very stout, is dark purple, and in this instance is twin-flowered. The fine dorsal sepal is suffused with purplish rose, and has ascending from the base some blackish purple feathered lines, the margin being pure white. The broad petals and lip are heavily tinged with reddish-purple.

It is a very fine flower, and although Cypripediums are now very numerous such productions are still rare. C. Harrisianum superbum, one of the early hybrids of Messrs. Veitch, seems to give excellent results where a strong constitution and dark colour are desired.

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

VEGETABLES AT SHREWSBURY.—Wonderful as are the collections of vegetables staged yearly at Shrewsbury, and the best seem to excel their predecessors each year, yet it is rather a misfortune than a boon that through the liberality of members of the seed trade there are so many classes for collections. Those who saw the keen fight at Edinburgh last autumn between Messrs. Beckett and Gibson will not readily forget their wonderful collections. Nothing seen at that great Show excited so much interest as did that vegetable fight. Whilst Shrewsbury is our greatest English exhibition, and offers

the finest opportunity for vegetable competitions in the kingdom, yet it lacks that one central class which would gather to itself the finest of vegetable productions the nation can obtain. There we see the giants in plant culture and in plant grouping, in cut flower production and arrangement, and in fruit production and arrangement, all brought into the keenest competition with each other, and for prizes that have no equals in value. In all these sections there are premier or challenge classes, the winners in which can certainly claim to be for the year the champions in their specialities. Would there were, amidst the great abundance of ordinary or trade classes for vegetables, one competition at least that stood out as the champion class! We saw Mr. Beckett easily walking off with the 1st prize in Messrs. Carter's class and Messrs. Mills' class. Mr. Gibson, with equal ease, took Messrs. Sutton's 1st prize in their class, and that of the Society's collection. Mr. Dymock took Messrs. Webb's 1st prize easily; and Mr. Pope won Mr. Sydenham's. Now all these collections do, of course, help to make a fine show, but this method of assorting or sharing the best prizes is not war, and it is war, and war to the knife, between these great competitors and others we want to see. Let each one exhibit in whichever of the trade classes he may desire, but if the Society could create out of their class for twelve kinds a splendid champion class, with prizes beginning at £12, followed by five others of proportionate value, and make it a condition that all 1st prize-winners of the present year should be bound to compete in the champion class also, what a grand and exciting competition we should see! I am not sure whether even the champion Grape class would have such interest. *A. D.*

Batsford.—At Batsford the subtle skill of the landscape artist has been combined successfully with Nature, that formed the framework upon which was developed, with, no doubt, much pains and toil, perhaps the happiest result of the kind anywhere to be seen in this country. "Milton alone," says Horace Walpole, "seems, with the prophetic eye of taste, to have foreseen modern gardening. The vigour of a boundless imagination told him how a place might be disposed that would embellish Nature and restore art to its proper office, viz., the just improvement or imitation of Nature. Describing Eden, he speaks of the river which, 'with many a rill,' watered the garden, and fed

'Flowers worthy of Paradise, which not nice Art
In beds and curious knots, but Nature boon,
Pour'd forth profuse on hill, and dale, and plain.'"

Such poetic expression may also be justly applied to the combination of Art and Nature so masterly and successfully carried out at Batsford. Were Milton alive now, and had the opportunity of walking up those hillsides of Batsford, by the little purling streamlet, with its numerous waterfalls and lakelets, adorned with many healthy gems of Marliac's hybrid Lilies, all in full and luxuriant flower of rich and various colour, the banks adorned with many varieties of Bamboo and a rich collection of rare trees and flowering plants, he might feel satisfied to find that his prophetic forecast of the "combination of Art and Nature" had been so happily and amply realised. Needless to say, our party, which consisted of members of the Birmingham and Midland Gardeners' Association, thoroughly appreciated the privilege so kindly granted to us by Lord Redesdale of seeing this lovely place, and are grateful to the head gardener, Mr. Garrett, for the pains he took in showing us round. *W. Miller, Berkswell.*

Peach Culture Out-of-Doors.—"North Devon" (p. 154), expresses surprise that I did not mention the "blister" disease that has, he asserts, caused great damage to Peach trees during the past few years, and which, in his opinion, is the reason why many growers have largely abandoned planting Peach trees out-of-doors. I may remind him that I did not deal with the subject of diseases in my article. The fact of the leaves becoming "blistered" occasionally during the months of April and May does not afford grounds for abandoning the planting of Peach trees out-of-doors. By picking off the affected leaves (if numerous only the worst should be pinched off, the remainder being removed when a favourable change in the weather takes place) the trouble is removed and the trees soon recover from the slight check which the sudden cold following a short period of warm genial weather caused in the flow of sap, and ample healthy foliage is again developed. As stated, "blister in the leaves" is caused by a [fungus which makes its appearance after a] cold following a short period of warm, moist weather. The growth of the midrib becomes restricted, the sap is thereby checked in its circulation, and consequently the tissue becomes swollen into inert masses. I have never experienced difficulty in dealing with the "blister," and indeed, none need be looked for where young healthy trees have been selected, planted, and subsequently treated as recommended in my article. The fact of "North Devon" putting forward "blister" in the leaves as the reason for many growers (presumably in Devonshire) having largely abandoned planting Peach trees out-of-doors, goes to prove that the culture and treatment generally bestowed on these

Fig. 68.—Weeping variety of Cupressus nootkatensis. (For text see page 166.)

trees have not been in accordance with their requirements in the favoured climate of Devonshire. *H. W. Wand.*

—— There is another reason, a local one it is to be hoped, besides those enumerated by Mr. Ward that operates against the cultivation of the Peach out-of-doors, and that is the poor flavour of the fruit when it arrives at maturity, compared to that grown under glass. Personally, I know of three widely separated gardens in Scotland where the Peach is grown outside on south walls, and, although the trees grow well and sometimes produce heavy crops, the flavour of the fruits is not to be compared with those grown under glass in the same gardens. Doubtless, care in planting and after-treatment such as Mr. Ward advises, has much to do with producing well-ripened wood, but it is, nevertheless, questionable if growers situated outside the more favoured southern counties can afford to overlook climatic conditions in the light-hearted manner Mr. Ward disposes of them. On the west-coast of Scotland which usually experiences a large proportion of dull, damp weather, the wood ripens very imperfectly, the shoots remaining green and retaining their leaves until they are forced off by the first frosts. Under these circumstances, the result is that the crop is produced, not upon the previous year's shoots as is the case in sunnier localities, but on spurs. *M. M. N.*

Thames Bank Peach.—In reference to Mr. T. Coomber's enquiry (p. 154) regarding this variety, I find that Mr. John Fraser, The Nurseries, South Woodford, Essex, includes it in his list of fruit trees. *H. W. Wand.*

Kochia scoparia.—Is *F. J.* (p. 154) aware that there are two kinds of Kochia sold under the specific name of scoparia? The best habited one sent out, I believe, by Messrs. Cannell a year or two ago is a very close-growing variety similar in habit to Cupressus erecta viridis, and it grows in a compact pyramidal bush form without trimming. Used as "dot" plants this type is apt to grow too large and requires pinching. I obtained seed this year under the same name from another firm, but the plants proved disappointing, the growths being long and spindly and not nearly so effective. I find the same disappointment has been experienced in several other gardens where seed of the inferior strain was procured from the same place. Many other growers have probably the same cause for grumbling as myself. *E. Trollope, Coombe Park Gardens, Reading.*

—— I was surprised to read (p. 154) that in order to have plants of this balloon-shaped Kochia in correct form some training is necessary. I have seen large numbers of plants raised under glass of perfect form when grown in the open and to which not the least training has been given. A greater surprise, however, was to see recently at Messrs. Sutton & Sons Seed Farm, Reading, superb and perfectly-shaped plants from seed-sown in the open ground. *A. D.*

Kochia scoparia var. trichophylla.—Having grown this plant for several years, I am interested in the note on p. 154. This is the first time I have heard of cutting the plants to obtain well-shaped specimens. Whilst not wishing to criticise this method, I may say that good plants can be grown without adopting this system. Mr. James says "in some cases it has been stated that the plants grown as Kochia scoparia are not true to name." This is a conclusion I have also arrived at. In spring, when potting the plants, several which did not give promise of becoming bushy were thrown away. In a bed of about 50 plants only two have failed to develop into good shapely specimens; this without any cutting whatever. When visiting Messrs. Sutton & Sons' trial grounds at Reading, recently, they had growing there the true K. scoparia, the variety trichophylla (splendid bushy specimens) and several intermediate forms; plainly showing that this plant comes very variable from seeds. What is at present sold as K. scoparia is for the most part the variety trichophylla. Eventually it will, no doubt, be possible to obtain the plant true from seeds when careful selection and fixing has been practised. The true K. scoparia is not worth growing, except for its botanical interest. *A. O., Kew Gardens.*

Beech Trees and Lightning.—On p. 112 a coroner is reported to have said "he had for years read that there was no record of Beech trees having been struck by lightning, and he believed it was an accepted fact that Beech trees were never struck during a thunderstorm." This seemed to me rather curious, for I know of three Beech trees in the Royal Gardens here which have been struck. One standing in the neighbourhood of tall Oak trees, amid an avenue of Liriodendron, was so damaged that the bark was split round the whole length of the tree, and it died in consequence the following year. The two other trees also stood not far from giant Oak trees, and they were entirely cut to pieces. *W. H. Wind, The Royal Gardens, Het Loo, The Netherlands.*

—— Should any person interested in this subject happen to be in this neighbourhood I shall be pleased to show him two Beech trees which have been struck by lightning, the one last year and the other four years since. The former had the bark stripped all round the trunk to the height of several feet, and the injury gradually tapered off almost to the top of the tree. I well remember the two terrific flashes that caused the damage, the trees struck being in close proximity to my house.

This is sufficient proof to me that the Beech is no more immune from injury by lightning than any other tree. No doubt other readers could supply similar instances. I may also mention that trees of Oak, Spanish Chestnut and Sycamore were growing close by the Beeches. *A. Young, Witley Court Gardens, Stourport.*

—— The correspondence on this subject is very interesting to me. During a long life, and notwithstanding close observation of trees, I have never known a Beech tree to be struck. After the inquest on those killed recently whilst under the shelter of a Beech tree, and the statement of the Coroner that he had visited the tree and found "not a leaf injured," I went to Burnham Beeches in the company of a gentlemen of much experience and authority and examined these unrivalled monarchs of the past. We soon found a healthy Oak that bore evidence of injury by lightning, but the surrounding Beeches only showed the results of natural decay. Although many of them are hollow and the trunks distorted through pollarding in former times, they are in splendid health and vigorous growth. It was truly a worthy act to secure these characteristic Beeches as national possessions. I am sorry to say that one of them, "The Queen of the Beeches," is dead, having been killed, in my opinion, by the large fungus that is sometimes fatal to trees of considerable age. I noticed the remains of the fungus where it had fruited outside the trunk. The dead tree stands at the side of the road leading to the refreshment houses, but there are in the vicinity other trees of the same kind and age in good health although hollow. *W. Roupell, Streatham Hill, S. W.*

THE YUCCA.—Surely the fine group of Yuccas represented in the *Gard. Chron.* for August 18 consists of Y. pendula not Y. gloriosa. Whether these be separate species or merely varieties of the same may be an undecided question, but Y. pendula is far the more desirable form, both on account of its more graceful habit and its far greater frequency in flowering. *Herbert Maxwell.* [The species shown was Y. recurvifolia, a form of Y. gloriosa. —ED.]

ROSES AND HOW TO GROW THEM, AND FERNS AND HOW TO GROW THEM. By G. A. WOOLSON. [London: WM. HEINEMANN]. As these two books belong to the same series they may be considered together. Both are full of information on apparently inexhaustible topics and probably an ever-ready public will appreciate them. The volume on Roses is partly drawn up from articles in *The Garden Magazine* and *Country Life* in America, and Mr. LEONARD BARRON furnishes a chapter to it. There are plenty of illustrations, and the letterpress includes cultural directions and lists of varieties suited for special uses. *Ferns and How to Grow Them* is "designed simply as a practical work for the benefit of the amateur Fern culturist." There is an abundance of pictures reproduced from photographs, and the whole makes an attractive volume. It should be noted that both "Roses" and "Ferns" are written with special reference to the cultivation of these plants in America.

PLANT PORTRAITS.

APPLE CALVILLE DUQUESNE.—A fine dessert Apple in season from November to January. Fruit globular, with a deep eye and short stalk set in a deep basin. Skin yellow, flushed with rose; flesh white, flavour excellent.—*Revue Horticole*, August 16.

ARISTOLOCHIA ORNITHOCEPHALA. — *Revue Horticole*, August 16.

CYPRIPEDIUM GERMAINE OPOIX.—A cross between "Madame Colinet" and C. Fairrieanum.—*Revue Horticole*, July 16.

OPHIOPOGON REGNIERI.—*Revue Horticole*, August 16.

Obituary.

MRS. H. BALLANTINE.—We have heard with much regret of the bereavement of Mr. H. Ballantine, whose wife died on the 17th ult. Mr. Ballantine is gardener to Baron Sir Henry Schröder, The Dell, Egham.

HENRY LUCKHURST.—Many of our readers will hear with regret of the death of Mr. Luckhurst, who was horticultural lecturer for the Derbyshire County Council, and a frequent contributor to the horticultural press.

SOCIETIES.

ROYAL HORTICULTURAL.

AUGUST 28.—The show on Tuesday last at the ordinary fortnightly meeting was smaller than usual, and there were few visitors, London now being in the condition it is customary to describe as "empty," though there are few indications of this to be seen in the streets.

Orchids were shown well, and the display of these flowers was probably as good or better than any previously made in the month of August. The ORCHID COMMITTEE recommended one First-Class Certificate and four Awards of Merit to novelties. The FLORAL COMMITTEE recommended five Awards of Merit, but the FRUIT AND VEGETABLE COMMITTEE did not have occasion for making any award to novelties. Messrs. SUTTON & SONS, however, made an interesting exhibit of Runner Beans, and a group of fine Melon fruits came from the Reading University College Gardens. In the afternoon a few new Fellows were elected, and a paper by Mr. R. H. CURTIS on "Phenology in its Relation to Horticulture" was illustrated with lantern slides.

Mr. S. MORTIMER, Rowledge, Farnham, Surrey, displayed three new show Dahlias. The petals were not of the best form, although the colours were good. He also showed a new Cactus Dahlia named John E. Knight.

HERR HENKEL, Darmstadt, showed some interesting plants of Abies lasiocarpa var. Arizonica under the name of A. Arizonica, var. Argentia. Some of the specimens were raised from seeds and others were grafted plants. The seedlings, which we presume were of the same age as the others, were about six times as large. This Californian Pine, which was figured in the *Gardeners' Chronicle*, March 2, 1901, is remarkable for its white, cork-like bark. H. HENKEL also showed some new species of Nymphæas.

Messrs. JAMES VEITCH & SONS, King's Road, Chelsea, showed five new species of Vitis, better known as Ampelopsis, most of which have been described in our columns. The most handsome was V. magolophylla. V. Henryana was figured in these columns October 28, 1905, and is very decorative. Senecio clivorum was shown in flower. Messrs. VEITCH & SONS also filled a goodly portion of one of the centre

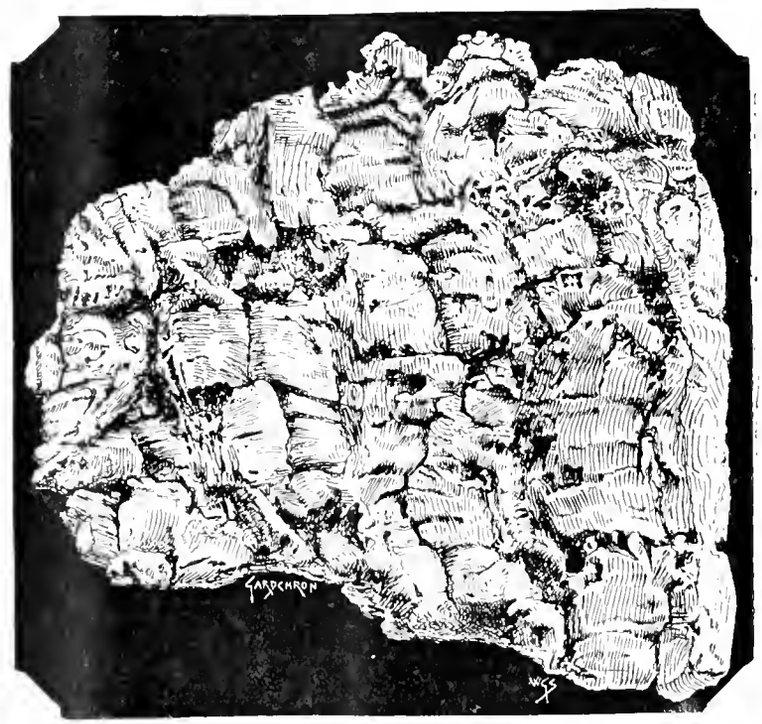

FIG. 69.—PORTION OF THICK, CREAM-COLOURED CORKY BARK OF ABIES LASIOCARPA, VAR. ARIZONICA.

Floral Committee.

Present: H. B. May, Esq., in the chair, and Messrs. C. T. Drnery, John Green, T. W. Turner, G. Reuthe, J. W. Barr, R. Hooper Pearson, John Jennings, W. Bain, C. J. Salter, Chas. Jeffries, E. T. Cook, Chas. E. Pearson, J. T. Bennett Poë, E. H. Jenkins, W. J. James, R. C. Notcutt, Amos Perry, and Jas. Walker.

Messrs. CARTER, PAGE & Co., 52 and 53, London Wall, E.C., staged an extensive collection of Cactus Dahlias. The exhibit was very representative, and the flowers embraced a wide range of colour. Adjoining the Cactus varieties was a collection of the miniature flowered Pompon Dahlias. (Silver Flora Medal.)

Messrs. JAMES STREDWICK & SON, Silver Hill Park, showed a number of new Cactus Dahlias. They were all good flowers, but not distinct enough from existing varieties, with the exception of one which will be found described under "Awards."

Messrs. HOBBIES, LTD., Dereham, Norfolk, showed vases of the large, coarse-petalled Dahlias known as the "Peony-flowered" strain. These flowers are suitable for decorative purposes, where a bold effect is needed from a distance. The petals, however, are very coarse, and a row of the beautiful Cactus type, which formed an edging to the group, made them appear the more so by comparison. The "Peony-flowered" type appears to flag very quickly, even if the stems are placed in water.

tables with decorative flowering plants—Begonias of the winter flowering type, Ixoras, greenhouse Rhododendrons, Eschynanthus grandiflorus, Swainsonia galegifolia, Leonotus Leonurus, Solanum Wendlandi, producing its magnificent flowers, whilst growing in pots of very small size; Crowea latifolia major with larger flowers than those of the type, &c. All of these showed the excellent cultivation for which this firm is renowned. (Silver Flora Medal.)

Messrs. HUGH LOW & Co., Bush Hill Park Nurseries, Enfield, N., showed a batch of the pretty Chironia ixifera that received an Award of Merit last year. Messrs. Low also showed some good Carnations.

HARRY JAMES VEITCH, Esq., East Burnham Park, Slough, showed spreading panicles of the yellow-flowered Koelreuteria paniculata, a hardy shrub which was figured in these columns November 5, 1887.

Messrs. H. CANNELL & SONS, Swanley, Kent, staged a semi-circular group of Cannas; the flowers showed the same high culture, beauty of colour, and breadth of petal one is accustomed to see in these flowers from the Swanley nursery, and the varieties were numerous. (Silver Flora Medal.)

Sir EDMUND LODER, Bart., Leonardslee, Horsham, Sussex (gr. Mr. W. A. Cook), showed a number of interesting hardy plants from his famed gardens. A single leaf of Gunnera

manicata was large enough to shelter half a dozen persons. The brilliant Berberidopsis corollina was in fruit. Calycanthus floridus was in both fruit and flower, and there were sprays of many other shrubs, Lilies, &c. (Silver Banksian Medal.)

Messrs. KELWAY & SON, Langport, Somerset, again showed an extensive collection of Gladioli. (Silver Flora Medal.)

Messrs. GUNN & SONS, Brookfield Nurseries, Olton, staged garden Phloxes in all the best varieties. A white kind of exceptionally dwarf habit attracted much attention, and will be found described under "Awards." (Silver Banksian Medal.)

Mr. AMOS PERRY, Enfield Chase, and Winchmore Hill, N., showed a selection of border flowers, and many varieties of hardy Nymphæas. (Silver Banksian Medal.)

Messrs. G. & A. CLARK, LTD., Dover, showed a seasonable array of hardy garden flowers. (Bronze Flora Medal.)

Hardy flowers were also shown by Messrs. BARR & SONS, King Street, Covent Garden, London, W.C.; by Mr. G. REUTHE, Keston, Kent; and Messrs. GEO. BUNYARD & Co., Maidstone. (Silver Banksian Medal.)

Mr. L. R. RUSSELL, Richmond Nurseries, Richmond, showed small pot plants of Codiæums (Crotons) in great variety.

Messrs. J. CHEAL & Co., Crawley, Sussex, showed a very large number of ornamental hardy trees and shrubs and others in flower. Oaks, Limes, Elders, Honeysuckles, Maples, Ashes, and other hardy trees were shown with variegated and curiously shaped leaves. Among the shrubs in flower we may instance Spiræas, Genistas, Hypericums, Veronicas, and Tamarix. Messrs. CHEAL also showed a very good collection of Pompon and single-flowered Dahlias. (Silver Banksian Medal.)

Messrs. THOMAS WARE, LTD., Feltham, Middlesex, showed Cactus and show Dahlias of good quality. (Silver Banksian Medal.)

Impatiens Olivieri was shown as flowering sprays by Sir TREVOR LAWRENCE, Bart., Burford, Dorking (gr. Mr. W. Bain). Sir TREVOR cultivates this new flesh-coloured species and I. Holstii out-of-doors during the summer season, where the latter species especially makes a very fine display.

Dahlia viridiflora, the green-flowered Dahlia, a monstrosity, which has been frequently figured in these pages, was shown by H. T. PITT, Esq., Stamford Hill, but on this occasion it was somewhat redundantly honoured by the further name "Doris Howard."

AWARDS.

Single Dahlia Fugi San.—A good single flower, of rich-buff colour with brilliant red coloured ring round the disc. Shown by Messrs. CHEAL & SONS. (Award of Merit.)

Cactus Dahlia Dr. G. G. Gray.—A variety of brilliant crimson colour, large size, good form, and having incurved claw-like florets. Shown by Messrs. JAMES STREDWICK & SON. (Award of Merit.)

Cactus Dahlia Princess Mary.—A very large, well-formed flower with rolled florets, scarcely so incurved as those of the preceding variety. In colour there are shades of orange and mauve, the general effect being one of coral—exceedingly pretty. Shown by Messrs. HOBBIES, Ltd. (Award of Merit.)

Gilia coronopifolia.—This is an annual or biennial species worthy of recommendation. The fine specimens shown by Messrs G. & A. CLARK, Ltd., Dover, had grown 4 feet high, and the flowering portion was nearly 2 feet in length. The flowers, as shown, are produced in axillary clusters, they are brilliant red in colour with ten fine white lines on the interior of the corolla, two on each segment. The corolla segments do not reflex, but are spread out flat. The leaves are very narrowly divided and taper to a fine point. The flowers are illustrated in the *Botanical Register*, t. 1691, but the spotting on the corolla segments is shown too conspicuously there, and the colour of the flowers has faded. In warm localities seeds may be sown out of doors in autumn, but in other places seeds should be sown and the plants grown in pots for planting out in May. It is an old plant, but is not often seen in gardens. (Award of Merit).

Phlox Tapis Blanc.—This is the dwarfest white perennial Phlox, described as never growing more than one foot in height. Some of the plants shown were not more than half a foot. The flowers are pure white, an inch and a half across, and apart from its dwarfness the quality is of the best. Numerous plants were shown by Messrs. GUNN & SONS, Olton, Birmingham. (Award of Merit.)

Orchid Committee.

Present: J. Gurney Fowler, Esq., in the Chair, and Messrs. Jas. O'Brien (hon. sec.), Harry J. Veitch, De B. Crawshay, Arthur Dye, W. Bolton, J. W. Odell, H. Little, W. Boxall, F. Menteith Ogilvie, A. A. McBean, G. F. Moore, H. G. Alexander, and J. Charlesworth.

Messrs. CHARLESWORTH & Co., Heaton, Bradford, were awarded a Silver-Gilt Flora Medal for a very fine group composed largely of their handsome hybrid Orchids, of which in the present group the beautiful and variable Cattleya Iris varieties took the lead, each end of the group having a selection of very fine varieties of it, scarcely two alike in colour, though the greater part had bronzy sepals and petals and some shade of ruby-purple in the lip. In the centre were a selection of the lilac-tinted Brasso-Cattleya Madame Chas. Maron, with one plant of the fine white B-C. Queen Alexandra, the bloom being a model in shape and with a finely-fringed labellum, the very handsome Odontoglossum Othello and other Odontoglossums; Miltonia Hyeana, with a much larger and more rose-tinted flower than the original shown at the last meeting, three clear white-flowered plants of Cattleya Gaskelliana alba, and C. Fabia, the neat Lælio-Cattleya Alcyone. Other Lælio-Cattleyas were in the group, which among other fine varieties of species included Epidendrum confusum, Brassia Lawrenceana longissima, Oncidium triuliferum, O. ornithorhynchum album, Angræcum japonicum, Cycnoches Egertonianum viride, &c.

Messrs. SANDER & SONS, St. Albans, were awarded a Silver Flora Medal for a very varied and interesting group comprising many rare Orchids. In the centre was an arrangement of the singular and beautiful Arachnanthe Lowii, fourteen drooping spikes of its extraordinary flowers being displayed, the yellow-ground basal ones being very dissimilar from the others. The four special novelties in the group were Lælio-Cattleya × elegans His Majesty, Cypripedium Baron Schröder var. ardens (for both of which see Awards), Lælio-Cattleya Bletchleyensis magnifica, a very large and richly-coloured flower, and L.-C. Mrs. Robert Measures (L.-C. elegans × L. xanthina), a very pretty and distinct hybrid with upright spikes of flowers, the sepals and petals of which were Indian yellow and the front of the lip violet-purple. Lælio-Cattleya "Henry Greenwood," var. The King, had a noble flower and very broad, finely-coloured lip.

JEREMIAH COLMAN, Esq., Gatton Park, Reigate (gr. Mr. W. P. Bound), secured a Silver Flora Medal for an effective group made up principally of many specimens of the good form of Lælio-Cattleya Nysa (L. crispa × C. Warscewiczii) raised at Gatton Park. Arranged with them were a very fine Cattleya, Mrs. W. J. Whiteley, a good Lælio macrostachya, Sobralia xantholeuca, the pretty and now rare Oncidium zebrinum, good Lælio-Cattleya Phryne and L. C. Bletchleyensis, Dendrobium rhodostoma, D. aureum, the pretty Spathoglottis Colmanii, Cattleya Parthenia, and a singular little hybrid raised at Gatton Park between Brassavola nodosa grandiflora and Lælia flava. In habit it comes nearest to Brassavola nodosa, having slender pseudo-bulbs and fleshy leaves. The flowers are in short spikes and about two inches across; the narrow sepals and petals are yellowish, with purple spots, the lip being white. The plant was named Brasso-Lælia fladosa.

R. I. MEASURES, Esq., Cambridge Lodge, Camberwell (gr. Mr. Smith), staged a small group for which a Silver Banksian Medal was awarded. It contained a plant of the rare Angræcum caudatum, with a spike of six flowers; the sepals and petals and the foot-long slender spurs were greenish, tinged with red-brown, and the labellum white. Also a box of fine strong plants of the handsome leafed Dossinia marmorata, a pale coloured Cypripedium between C. Charlesworthii and C. Dayanum, C. × Unixia superbum, Lælio-Cattleya elegans, &c.

Messrs. HUGH LOW & Co., Bush Hill Park, were awarded a Silver Banksian Medal for a varied group in which were noted a selection of Dendrobium Phalænopsis, D. sanguinolentum, Catasetum macrocarpum, Stanhopea oculata, S. Wardii, Oncidium microchilum, O. carthaginense, O. oblongatum, a very clear white Cattleya Gaskelliana alba, and other Cattleyas; Phalænopsis violacea, Low's variety, very fine in colour; Lycaste leucantha, Cypripediums, &c.

Messrs. STANLEY & Co., Southgate, received a Silver Banksian Medal for an effective group, in the centre of which was a finely flowered plant of Oncidium Stanleyi (see Awards). With it were a very dark form of O. curtum, Oncidium incurvum album, Cypripedium A. de Lairesse, several Lælio-Cattleya elegans, some good examples of Odontoglossum Harryanum, O. Hunnewellianum, Cattleya Harrisoniana, C. bicolor, &c.

Major G. L. HOLFORD, C.I.E., C.V.O. (gr. Mr. H. G. Alexander), sent three very fine Orchids, of which Cattleya Iris "Countess of Morley," a noble flower quite unique in colour, secured the only First Class Certificate awarded. The others were Lælio-Cattleya Berthe Fournier var. Mrs. Benson, a very pretty and fragrant variety with rose-purple coloured flowers having rosy crimson labellum, with fine gold lines at the base; and a very strong plant of Sophro-Cattleya Chamberlainiana triumphans, with nine flowers.

FRANCIS WELLESLEY, Esq., Westfield, Woking (gr. Mr. Hopkins), sent Cattleya vestalis, Westfield variety (maxima × Dowieana aurea), a good light-coloured flower, with the veining of C. maxima distinctly shown in the lip; and Cattleya bicolor, Westfield variety, a finely formed flower with broad yellowish-green sepals and petals and rose-crimson lip with white margin in front.

The Honourable WALTER ROTHSCHILD, M.P., Tring Park, Tring (gr. Mr. Arthur Dye), again sent the handsome Cattleya Hardyana, "Tring Park variety," which had previously secured a First-Class Certificate, and a good example of Brasso-Cattleya Madame Chas. Maron (B. Digbyana × C. Warscewiczii).

E. ROBERTS, Esq., Park Lodge, Eltham (gr. Mr. W. Carr), showed Cypripedium Olga Bagshaw (callosum × oenanthum superbum), a pretty hybrid.

R. G. THWAITES, Esq., Streatham (gr. Mr. Black), showed the beautiful Odontoglossum crispum xanthotes Charlesworthii in fine condition.

Col. H. CARY BATTEN, Abbot's Leigh, Bristol, sent Lycaste leucantha.

AWARDS.

FIRST-CLASS CERTIFICATE.

Cattleya Iris Countess of Morley (bicolor × Dowiana aurea), from Major G. L. HOLFORD, C.I.E., C.V.O. (gr. Mr. H. G. Alexander). One of the most beautiful of a very handsome class. Sepals and petals of a pretty dark apricot-yellow tint, lip finely developed with a yellowish ground colour tinged with clear rose-pink.

AWARDS OF MERIT.

Sobralia Lowii, from HENRY LITTLE, Esq., Baronshalt, Twickenham (gr. Mr. Howard). A rare, dwarf growing species with small bright rose-purple coloured flowers.

Lælio-Cattleya elegans His Majesty, from Messrs. SANDER & SONS. A very remarkable variety of good size, fine colour, and producing a remarkable number of flowers, the two spikes bearing 12 and nine flowers respectively. The sepals and petals are purple, and the front of the lip rich claret-purple.

Cypripedium Baron Schröder, var. ardens, from Messrs. SANDER & SONS. A fine variety, differing from the original form in the heavier and broader dotted purple lines on the dorsal sepal and in the generally darker tint.

Oncidium Stanleyi, from Messrs. STANLEY & Co., Southgate. A beautiful natural hybrid, supposed to be a cross between O. Marshallianum and O. curtum, and bearing evidence of the former in the sepals and petals, and the latter in the lip, which is large and of clear yellow colour. The sepals and petals are yellowish with light-brown markings. The fine plant bore two spikes of 121 flowers.

CULTURAL COMMENDATION.

To P. L. HUDSON, Esq., Pampisford, Cambridgeshire, for a very fine specimen of Cypripedium Charlesworthii with 15 flowers.

Fruit and Vegetable Committee.

Present. Geo. Bunyard, Esq., Chairman, and Messrs. Jos. Cheal, W. Bates, S. Mortimer, A. Dean, A. R. Allan, Geo. Kelf, H. Farr, H. J. Wright, J. Davis, J. Vert, John Lyne, F. O. Lyne, Geo. Reynolds, J. Jaques, J. Willard, C. Foster, Owen Thomas, and H. Markham.

Messrs. GEORGE BUNYARD & Co., Maidstone, Kent, showed a collection of fruits including

Apples, Pears, Plums, Peaches, Cherries, Nectarines, and Melons. The hardy fruits were principally of dessert varieties, especially good dishes of Apples being Lady Sudeley, Duchess's Favourite, Beauty of Bath, and Calville Rouge Precôce. Of Pears Williams' Bon Chretien, and Souvenir du Congrès were among the best. Of Plums there were some very fine fruits of the old Greengage.

UNIVERSITY COLLEGE, Reading (Horticultural Department: superintendent, Mr. Foster), staged a collection of about 40 Melons in many varieties. The group was prettily decorated with trailing sprays of Ampelopsis and other coloured foliage. Good examples of Earl's Favourite, Hero of Lockinge, Superlative, &c., were shown.

Messrs. SUTTON & SONS, Reading, showed an interesting collection of dwarf, runner, wax-podded and other coloured Beans. A good, long, straight variety of dwarf Bean is Princess of Wales. Among the runner type, the now well-known Abundance was shown in fine condition. Sutton's A1 is also a good Runner Bean, the pods being very dark in colour and of a large size. We also noticed Prize-winner, Best of All, and a long, pale-coloured seedling, labelled Seedling No. 2. There were also coloured varieties of Beans—blue, red, yellow, &c.; the wax pods and the Butter Beans that are largely grown on the Continent being of a beautiful yellow colour. More curious than all are the striped varieties—bright red on a yellow ground—such as Striped Red New Zealand and the pretty Fire Fly. Mont d'Or is a wax-podded variety of a lovely shade of yellow.

Messrs. WILLIAM PAUL & SON, Waltham Cross, Herts., showed fruit trees in pots: Apples, Pears, Plums, Figs, Nectarines, and Peaches. We may mention a fine plant of Apple Wealthy and a good specimen of Grosse Mignonne Peach.

Messrs. CARTER, PAGE & Co., 52 and 53, London Wall, London, showed 34 distinct varieties of Tomatos. All the types were included—the round, crinkled, yellow-fleshed and dessert, the Cherry, the Currant, the Plum, &c. Some very good fruits of the Perfection type were seen. Adjoining the Tomatos were many ornamental Gourds.

ROYAL HORTICULTURAL SOCIETY OF ABERDEEN.

AUGUST 23, 24, and 25.—The annual exhibition of this Society was held on the above dates in the Duthie Public Park, Aberdeen, the use of which was kindly granted by the City Council. The entries this year were somewhat fewer than those of last year, but what was lacking in numbers was amply made up in quality. So far as the general arrangements of the marquees were concerned, much the same plan as in former years was carried out by the secretary, Mr. J. B. Rennett, Advocate, Aberdeen.

PLANTS IN POTS.

A first glance around showed that there was no entry in the class for tables of stove or greenhouse plants, arranged for effect, 8 feet by 6 feet. The absence of these beautiful exhibits recalled to mind the splendid records made in this class by Mr. John Proctor, when head gardener to the late Sir William Henderson, of Devanha, Aberdeen. The Silver Medal for the best specimen plant in flower went to Mr. ALEXANDER BREBNER, Dalhebity, for Disa grandiflora. It was a fine specimen, well grown, and having about four dozen flower trusses. Mr. ALEXANDER DUNCAN, Albyn Place, Aberdeen, took 2nd honours with a fine Ixora Williamsii. The Silver Medal for the best specimen foliage plant was worthily gained by Mr. J. W. BREBNER, Ardo, Bellhelvie, with a specimen of Aspidistra lurida variegata—a large plant, and shown in fine health. Second honours went to Mr. DUNCAN, Kepplestone, for a remarkably well-grown Pandanus Veitchii. Ferns were a very fine show. Mr. W. S. MACKIE, Morken, Cults, led for the best stove or greenhouse Ferns; while the Silver Medal for the best six Ferns (at least three distinct varieties) went to Mr. ALEX. DUNCAN, Kepplestone. The collections of Orchids and Crotons, for which in each case Mr. DUNCAN, Albyn Place, Aberdeen, deservedly carried off the chief honours, were exceedingly good. This successful gardener was also placed first for Dracænas. For Zonal Pelargoniums the Silver Medal went to Mr. WILLIAM MACKIE, Morken. For the best six plants for table decoration the Silver Medal and likewise 2nd place were worthily earned by Mr. J. PETRIE, The Gardens, Crathes Castle, Kincardineshire. Other leading prizemen in this division not already mentioned included Mr. GEORGE MAITLAND, Woodside, Aberdeen; Mr. A. GILLESPIE, Northfield Place, Aberdeen; and Mr. JAMES ANDERSON, Mealmarket Street, Aberdeen. Amateurs also made a good display, and, although their tables were just a little crowded, the show they made evoked no little admiration. For Petunias they beat the professionals. The leading places were taken by Mr. JAMES MORGAN, Roslin Street, Aberdeen, and Mr. GEORGE MAITLAND, Great Northern Road, Aberdeen.

CUT FLOWERS.

The drought experienced in the late spring and early summer, with slight frost later on, were not conducive to bringing flowers, fruit and vegetables to their fullest maturity, and those that did survive that trying period suffered from the effects of the violent thunderstorms which recently prevailed. With all these drawbacks, however, the cut flowers upheld the traditions of the Royal Horticultural Society of Aberdeen. There was a capital display of Roses, the Silver Cup for the best 24 blooms, H.P. and H.T., or either, named, dissimilar, going to Mr. GEORGE MCLENNAN, Fetteresso Castle, Kincardineshire, for a very fine entry. Mr. ALEX. DOUGLAS, Kepplestone House, was 2nd. Mr. A. HARPER, Ruhislaw Park, Aberdeen, gained the Silver Medal for the best 12 blooms, his entry being a very meritorious one. For Pompon Dahlias and Cactus Dahlias Mr. J. D. CROZIER, Durris, Kincardineshire, took both the Silver Medals with very fine entries. Mr. ALEXANDER BREBNER, Dalhebity, was also very successful for Cactus Dahlias. For 12 bunches of hardy flowers Mr. JOHN PETRIE, Crathes Castle, deservedly won the Society's Silver Medal. Among the other names worthy of mention we must include Mr. JAMES ANDERSON, Aberdeen (Asters); Mr. JOHN GRIEVE, Woodside (French Marigolds); Mr. WILLIAM COUTTS, Ellon; Mr. ALEXANDER DOUGLAS, Kepplestone House; Mr. ALEX. GRIGOR, Fairfield House, Aberdeen; Mr. W. S. MACKIE, Morken; Mr. JOHN PETRIE; Mr. W. COUTTS, Ellon; Mr. WILLIAM SCORGIE, Springhill House; and Mr. JAMES ANDERSON, Aberdeen. The display of Sweet Peas was very good, the best being from Mr. ALEXANDER GRIGOR, Fairfield. The display of bouquets and bouquets for table decoration were as good as have ever been shown in Aberdeen—and that is saying much. Mr. ALEXANDER GRIGOR showed some beautiful specimens of hand bouquets and brides' bouquets, and also buttonhole bouquets. Special mention should be made of the exhibits in this tent from Mr. JAMES STRACHAN, Cruickshank Botanic Gardens, Aberdeen, for which he was deservedly awarded the Society's First-class Diploma of Merit.

Mr. GEORGE JOHNSTON, florist, 473, Union Street, Aberdeen, made his first appearance at this show as a florist, and his handiwork evoked the admiration of all who looked upon it. Mr. JOHNSTON carried off the leading honours for wreaths, hand bouquets (colours), and spray or shower bouquet of white flowers. Messrs. KNOWLES & SONS, florists, Aberdeen and Kent, had the leading prize for sprays suitable for ladies' wear. For Roses, Messrs. ADAM & CRAIGMYLE, Aberdeen, and Messrs. JAMES SIMPSON & SONS, Dundee, came out grandly, the local firm's exhibits being greatly admired and well worthy chief honours.

FRUIT AND VEGETABLES.

Considering the poor season hardy fruits were well represented, and the quality was good. Gooseberries and Strawberries were not exhibited in such large numbers as is usual, but the quality was well maintained. Blackberries were the out-standing feature, both in quality and numbers. Grapes were poorly represented, and were distinctly under the average. The honours for Grapes were divided between Mr. A. DOUGLAS, Kepplestone House, and Mr. PETRIE, Crathes Castle. Tomatos were of good quality but lacking in numbers. Apples and Pears were neither numerous nor of average quality. Mr. J. FERGUSON, Linton Gardens, Dunecht; Mr. PETRIE, Crathes Castle; and Mr. WILLIAM SCORGIE, Springhill House, won prizes for Apples and Pears. Melons were rather poor, which must be attributed to the dull weather. Honourable mention in the fruit classes must also be made of Mr. WILLIAM HARPER, Perth; Mr. J. SMITH, Countesswells; Mr. WILLIAM COUTTS, Ellon; Mr. GEORGE TAYLOR, Inchgarth: and Mr. J. FERGUSON, Linton Gardens.

VEGETABLES were fairly well shown. Potatos were well represented. Mr. FRANK KINNAIRD, Broomhill, Aberdeen, and Mr. WILLIAM LAWSON, Oakland School, Aberdeen, were the chief winners in the professional section for best collections.

MISCELLANEOUS EXHIBITS.

Messrs. STORIE & STORIE, Glencarse, near Dundee, had a table of Apples, Pears and Plums in pots. Messrs. KNOWLES & SONS, Aberdeen, had a fine display of wreaths, crosses and bouquets. Messrs. BEN REID & Co., Aberdeen, showed a collection of plants and flowers, their stand measuring over 100 feet long. It proved both interesting and instructive, and was much admired. Messrs. W. SMITH & SON, Aberdeen, had pot plants, cut flowers, and floral decorations. It was one of the finest exhibits ever seen in Aberdeen. Messrs. COCKER & SONS, Aberdeen, the well-known Rosarians, were worthily represented. Their devices and special exhibits of bouquets, &c., excited much admiration. Mr. M. H. SINCLAIR, florist, Aberdeen, had a choice display of cut flowers, including a splendid collection of American Tree Carnations and a fine assortment of giant-flowered Sweet Peas.

DEVON AND EXETER HORTICULTURAL.

AUGUST 24. The annual exhibition of the above society, held on this date in Northernhay Park, was, taken on the whole, equal to the standard of past years, although the absence of a few of the leading growers of vegetables was noticed. The entries totalled fewer than last year. The exhibits of Grapes were a feature.

FLOWERS: OPEN CLASSES.

In a class for 18 Dahlias of the show and the fancy types, in not fewer than 12 distinct varieties, the 1st prize was won by Mr. W. B. SMALE, Torquay. Among his best flowers were Arthur Acock, Purple Prince, J. T. Saltmarsh and Miss Cannell.

The similar class for 18 Double Cactus Dahlias, in 12 distinct varieties, was won by Messrs. JARMAN and Co., Chard, the collection including Cockatoo, Pearl, Conrad, and others. (A protest was entered because 15 varieties were shown in this collection, but the judges interpreted the reading of the schedule as not fewer than 12 distinct kinds.)

Competition was keen in the class for a decorated table measuring 4 feet by 8 feet. The schedule allowed both fruit and flowers to be used, but no Orchids. The 1st prize was won by W. BROCK, Esq., Parkerswell (gr. W. Rowland), for an exceptionally pretty table, the subjects used being Gloriosa superba, Francoa ramosa, Montbretias, Smilax, and Gypsophila.

PLANTS.

W. BROCK, Esq., was the only competitor in the class for six stove and greenhouse plants, and he was awarded the 1st prize for good specimens of Ixora fulgens, I. Williamsi, Chironia ixifera, Dipladenia amabile, and Stephanotis floribunda. Mr. BROCK was also 1st in the class for six stove and greenhouse Ferns, with fine specimens. The best six Adiantums, in distinct varieties, were shown by Mrs. C. HEARN, Alphington (gr. G. J. Anning). The plants included A. decorum, A. grandiceps, A. Veitchii, and A. cuneatum.

Mr. BROCK was again to the front for a collection or group of plants arranged in an oval and occupying an area of 11 feet × 15 feet. The principal subjects in the exhibit were Codiæums, Abutilons, Coleus, Humeas, Campanula pyramidalis, and Lilium auratum. The second prize was awarded Mr. O. BURTON, Digby's, for a nice group in which standard Fuchsias were effectively introduced.

Mr. BURTON was also 1st for six specimen Fuchsias, for six single flowered tuberous-rooting Begonias, for six Zonal Pelargoniums, and for six Coleus. In the classes for six double-flowered tuberous-rooting Begonias, six Caladiums, six Gloxinias, and three pots of Liliums, H. TOWNSEND, Esq., Exeter (gr. E. Phillips), won 1st prize in each case, his Caladiums being especially good. Competition in the specimen plant classes was far from strong; in several cases there was but a single entry.

Mrs. C. HEARN won the 1st prize for foliage Begonias.

CUT FLOWERS.

The best 12 bunches of hardy or perennial flowers in distinct kinds were shown by Col. SANFORD, Nynehead Court (gr. S. Kitley), 2nd Mrs. SAVILE, Barley House (gr. J. Rogers). Among the prizewinners in the separate classes for cut flowers were Messrs. B. C. SHEPHERD, J. COPP, Mrs. WEBBER INCLEDON, Rev. E. E. HEATHCOTE, Dr. SAMWAYS, Sir DUDLEY DUCKWORTH KING and Col. GUNDRY (gr. A. Shackelton). Colonel GUNDRY'S Sweet Peas were remarkably fine, being large and with long stems. Notable varieties in his exhibits were Bolton's Pink, Helen Lewis, John Ingman, Gladys Unwin, King Edward VII., Dorothy Eckford, and Lady Grisel Hamilton.

FRUIT.

For the President's Challenge Cup and special prize for a collection of six dishes of dessert fruits there was strong competition. The first prize was won by Sir DUDLEY DUCKWORTH KING, Wear House (gr. S. Baker); 2nd, H. ST. MAUR, Stover Park (gr. G. Richardson).

The premier collection contained White Muscat of Alexandria Grapes, Royal Jubilee Melon, Humboldt Nectarine, Hale's Early Peach, Brown Turkey Fig, and Williams' Bon Chrétien Pears.

The best three bunches of Muscat of Alexandria Grapes were also shown by Sir DUDLEY KING. He was also 1st for Black Alicante Grapes with three well-grown bunches.

For Madresfield Court and Black Hamburgh Grapes Messrs. B. C. SHEPHERD and H. ST. MAUR were 1st, respectively.

The best Peaches were displayed by J. H. LEY, Esq., Trehill (gr. J. S. Harding), he having beautiful fruits of Hale's Early.

Mr. B. C. SHEPHERD had the best Nectarines.

Mrs. KNIGHT-BRUCE, Exminster (gr. J. Way), had the best green, or white-fleshed Melon in a small but highly-flavoured fruit of Hero of Lockinge.

The premier dish of Pears of any variety was shown by Sir DUDLEY KING, the kind being Williams' Bon Chrétien, of superb quality and very beautiful in colour.

The 1st prize for dessert Apples went to Col. SANFORD.

For culinary Apples Mrs. C. HEARN and Rev. E. E. HEATHCOTE were equal 1st with Ecklinville Seedling and Lord Suffield respectively.

Rev. F. A. HAMILTON-GELL, Winslade (gr. G. T. Barnes), was 1st in a class for yellow Plums with Jefferson's Gage, and for purple or red Plums (not Gages) with Kirke's Seedling.

Mr. J. H. LEY had the best Morello Cherries, and Dr. SAMWAYS the best Red Currants.

VEGETABLES.

The prize for a collection which included Ailsa Craig Onions, Autumn Giant Cauliflower, Eclipse Tomato, Tender and True Parsnip, Best of All Runner Beans, Dobbie's Selected Red Celery, New Intermediate Carrot, Dobbie's Champion Leek, and Factor Potato was won by Mr. J. H. LEY, Trehill; 2nd, B. C. SHEPHERD, Esq. (gr. J. Stuckey.)

The Onions were exceptionally good, the 1st prize for these being taken by Sir DUDLEY KING; 2nd, T. KEKEWICH, Esq., Peamore (gr. J. Abraham).

Mr. T. KEKEWICH was 1st in a keen competition for Carrots, both in the class for Horn varieties, and the long or intermediate.

The 1st prize for Beet was awarded the Earl of PORTSMOUTH (gr. J. Vickery), who was also 1st for Kidney Potatos.

Sir DUDLEY KING was 1st for Tomatos with the variety Eclipse.

TRADE EXHIBITS.

Messrs. ROBERT VEITCH and SON, Exeter, exhibited their new Rehmannia "Pink Perfection," a fine collection of Gladioli, including Groff's Canadian Hybrids in the new blue shades, Dendromecon rigidum and other interesting new plants. Messrs. W. B. SMALE and SON, Torquay, showed their new Dahlia Jeanne Charmet, and a pretty, deep pink decorative Dahlia named Phyllis; Mr. W. J. Godfrey, Exmouth, staged a Cactus Dahlia of bright pink shade named Kremhilda, and a fine batch of Solanum Wendlandi. Messrs. JARMAN & Co., Chard, showed their new varieties of Sweet Sultan, also Dahlias, and Roses.

Other exhibits were shown by Messrs. J. WALTERS, Exeter; SAUNDERS & BISS, horticultural builders, and TUPLIN & SONS, Newton Abbot.

AGRICULTURAL, MARKET GARDENERS' & COTTAGERS' INDUSTRIAL SHOW.

AUGUST 21.—In the grounds of Norton Park, Bredon's Norton, near Tewkesbury (by the kind permission of Miss Woodhull), the Bredon's Norton and District Agricultural, Market Gardeners and Cottagers held their first horticultural show on the above date.

The gathering owed its success largely to the efforts of the hon. secretary, Miss Edith Bradley, who is already well known in the agricultural world, and more especially to women agriculturists, being a firm believer in the part which women can, and will take in its lighter branches, and that by starting a new movement in this particular district it would prove to throw open wider the door for women's employment, and stem the tide of those who would otherwise turn their backs to the land.

At two o'clock the Show was formally opened by Lord Coventry. Miss Bradley read a report in which she expressed a wish that the Show might become an annual one, and also the satisfaction it gave her to be able to announce that a woman had carried off the 1st prize for Cottage Gardens.

Lord Coventry said that for some time past he had wished to start a co-operative bank, on the lines of those already working in Italy, Switzerland, and Germany, but, for various reasons, amongst them the want of a good secretary, such a plan had so far been impossible. Then, speaking to the farmers, his Lordship said he should like to see more Corn grown in England, for if cut off from our grain imports, we should have but one month's supply in the country. If Parliament would give power to the various County Councils to buy stacks of Corn from the farmers, and keep the grain for national use, in case of war, this would, in some measure, prevent the great rise in the price of bread should war occur.

The entries for exhibits were over 375, one of the most interesting being models and plans for a single and pair of cottages, the price of the former to be £400, and of the latter £500 to £600, the prizes being given by Miss Woodhull, who intends to erect the building on her own estate, should the model meet with her approval. The cottage awards were not given at the Show. One, a beautiful little model of a single six-roomed cottage, inscribed "Pro Bono Publico," was charming, both in colour and design, with its quaint porch and long low windows.

Facing this exhibit was a stand of bottled fruit, exhibited by the Bredon's Norton School of Gardening. Asparagus, fresh and green as when cut in the garden, and many delectable fruits, were temptingly displayed.

The centre of the tent was given to Cottage exhibits, fruit and vegetables, seven entries for table decorations, and the "Mercia Antique Stall."

Demonstrations were given during the afternoon in: Fruit Bottling, by Miss May Crooke; Bee-Driving, by the Rev. E. Davenport, Worcester County Council; and Butter-Making and Milk Bottling, by Miss Jean Mason, N.D.D., of the Far Forest Dairy.

At 3.30 a parade of tradesmen's and market gardeners' turn-outs took place. A novel competitor was a woman market gardener, who was attractively attired in red coat and cap; she is well known in the neighbourhood. *A Daughter of Ceres.*

SCHEDULE RECEIVED.

WINCHESTER HORTICULTURAL SOCIETY'S autumn flower show, to be held on Tuesday & Wednesday, November 13, 14, in the Guildhall, Winchester.

GARDENERS' DEBATING SOCIETY.

CROYDON AND DISTRICT HORTICULTURAL.

—On Wednesday, the 15th inst. about 40 members and friends of the above society visited the famed gardens of Leonardslee, Horsham, the residence of Sir Edmund G. Loder, Bart. Many objects of interest in these gardens make up a collection rarely met with, and not only the plants, but the beautiful undulating landscape in its natural picturesqueness claims attention in every respect. Sir Edmund, whilst being a keen horticulturist, is also a zoologist of no mean repute, and his collection of animals from all parts of the world enhances the interest of the place. Mr. Cook, the gardener and an old member of the society, personally conducted the visitors through the gardens, and nothing was lacking on his part to make the visit enjoyable.

MARKETS.

COVENT GARDEN, August 29.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday, by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate, not only from day to day, but occasionally several times in one day.—ED.]

REMARKS.—English Tomatos are still very plentiful and 3s. for 12 lbs. is the top price now obtainable. Nectarines are scarce. Peaches are a little dearer owing to less quantities arriving at the present time. Trade is steadily improving. *E. H. Rules, Covent Garden, Wednesday, August 22, 1906.*

POTATOS.

Lincolns, 60s. to 65s.; Bedfords, 60s.; Kents, 65s. to 70s.; Blacklands, 55s. to 60s. Trade is very dull. *John Bath, 32 and 34, Wellington Street, Covent Garden*

COVENT GARDEN FLOWER MARKET.

The market now presents only a very dull appearance. In flowering plants Chrysanthemums are the leading feature, and sell fairly well, besides the pot-plants, many of which are now very good, large quantities are taken up from the ground and sold in boxes for planting. Asters are also sent to market in the same condition and are useful for filling up spaces in the garden where annuals and other early flowers have passed away. Asters in pots realise very low unremunerative prices. There are still good zonal Pelargoniums, also a few Ivy-leaved sorts, but the "shows" and "regals" are now nearly finished for the season. Lilliums, of various sorts, and Campanulas are good from several growers, but there are also some very poor plants of Campanula. Double Zinnias, Coreopsis, and Verbenas are still satisfactory. White Marguerite are plentiful. Most of the Fern growers continue to keep their stands well filled with useful plants. It is remarkable that Palms are now cheaper in Covent Garden market than they were in Belgium. A pedistras still maintain their prices, but as these are now over plentiful in some nurseries they may not continue to do so. Cyperus alternifolius is in good condition now, but this plant is not such a favourite as formerly. Eulalia japonica variegata which was much in demand a few years ago cannot be sold easily.

CUT FLOWERS.

Trade continues to be very uncertain, and prices are very low. Lilium longiflorum has been down to 1s. per bunch, for good blooms, L. lancifolium album has sold at 6d. to 1s. per bunch, L. lancifolium melpomene and L. tigrinum are also good. Roses are now a little dearer, or, at least, some of them are, but it is difficult to quote prices. After the best have been selected the remainder have to be sold for what little they will fetch, and hawkers take them out in large baskets. Carnations do not sell much better; there are still a few fairly good "Malmaisons." and "American" or "tree" Carnations are almost as good now as they were early in the season. Sweet Peas are nearly finished for the season, they have been marketable since early in February. Lily of the Valley is over plentiful; Gardenias, Stephanotis, Tuberoses, Eucharis, &c., are all well supplied, and Gladioli, Gaillardias, Coreopsis, and other hardy flowers are over abundant. Asters, in distinct colours, are seen all round the market, but now there are fine blooms of Chrysanthemums, fewer Asters will be needed. The beautiful Chrysanthemum blooms now coming in would realise more money in October. *A. H., Covent Garden, Wednesday, Aug. 29, 1906.*

ENQUIRIES AND REPLIES.

RHUBARB.—Will any reader of the *Gardeners' Chronicle* please state their experience of the variety of Rhubarb known as Burbank's Winter Red? Does most of it persistently run to seed? *J. T., King's Norton.*

ANSWERS TO CORRESPONDENTS.

ARABIS DISEASED: *Fairmill.* The plants are attacked by white rust, Cystopus candidus. The disease has probably spread from some neighbouring cultivated plant or weed, as the fungus occurs on every plant belonging to the wallflower family. Infection only takes place during the seedling stage, hence if the seed bed is made in soil that is not infected there is no danger of the disease appearing again.

BOOKS: *T. C.* An account of Douglas' life was published many years ago in Sir William Hooker's *Companion to the Botanical Magazine.* It is hardly likely that you will be able to obtain that work, but a condensed account is given in the *Manual of Coniferæ* published by Messrs. James Veitch & Sons, King's Road, Chelsea. You might refer also to the recently issued work, *Portraits of Botanists.* Details of Drummond's career might also be found in Sir William Hooker's work already referred to. A very brief summary of the work of both the botanists mentioned is given in a *Biographical Index of British and Irish Botanists,* by Britten & Boulger, and published by West, Newman & Co.

BOUVARDIAS, &C., INJURED: *M. P.* The Bouvardias are injured by a fungus, Botrytis cinerea. This suggests that the plants have been grown in too damp an atmosphere. Spray, or better, immerse the affected shoots in a solution of water containing a wineglassful of formalin to the gallon. The Asplenium is injured by thrips.

DAHLIA FLOWER BUDS FAILING TO OPEN: *J. W. M.* We cannot assign any reason for the flowers not opening. There is no disease present to account for it.

HONEY DEW: *H. W.* There is no reason for supposing that the Honey Dew which drops from the leaves of Lime trees is due to any other cause than that of the agency of insects, the insect which is chiefly concerned in this matter being one of the Aphides Pterocallis tiliae, though it is possible in places that some other species is associated with it.

NAMES OF FRUITS: *G. H. W.* Apple Mr. Gladstone.—*Nectarine.* Peaches: 1, Sea Eagle; 2, Nectarine Peach; 3, Princess of Wales; 4, Not recognised. The Nectarines were over-ripe when packed and were in a state of pulp when received. You ask for a list of the best early and late varieties of Peaches and Nectarines. *Peaches.* Early: Duchess of Cornwall, Alexander, Amsden June, Hale's Early. Late: Golden Eagle, Lady Palmerston, Gladstone, Walburton Admirable. *Nectarines.* Early: Cardinal, Early Rivers, Lord Napier; Late, Victoria —good when grown under glass and of excellent flavour, green; Spenser, Newton. Pine Apple is also an excellent variety, but it is not so late in ripening as above. *Grape.* The best black variety for size and flavour is Madresfield Court.—*Interested.* 1, Stirling Castle; 2, Bismarck; 3, Belle de Pontoise; 4, Lady Sudeley; 5, Lady Lennox. Will correspondents sending fruits to be named kindly forward them when fully matured. It is difficult to identify Apples and Pears when they are little more than half-grown.

NAMES OF PLANTS: *D. E.* Leycesteria formosa. —*J. M.* Photinia serrulata.—*H. W.* Colutea arborescens, the Bladder Senna.—*D. M. L.* Weigela (Diervilla) rosea.—*Hortus.* 1, Sempervivum Lindleyi; 2, Cotyledon farinosa; 3, Cotyledon linguæfolia; 4, Mesembryanthemum polyanthum; 5, Iberis sp. probably sempervirens; 6, Lamium maculatum.—*B. L.* Withania coagulans.—*Rayner.* Certainly not Tarragon.—*Doubt.* 1, 2, 3 and 5, we are in doubt also, as well we may be from such specimens; 4, Sedum Ewersii; 6, Senecio maritima; 7, Epiphyllum truncatum; 8, Poinsettia pulcherrima; 9, Vallotta purpurea. Next time send better specimens, our time is precious.—*J. M.* Probably Campanula isophylla, but why trouble us with such a wretched scrap? It is not fair to us or our readers to whom our time is due, to do so.—*Zebra.* Statice sinuata.—*W. H. L.* Jasminum nudiflorum, so far as we can tell from the miserable scrap sent. If that is the plant, you can move it in the autumn. It is a most desirable winter-flowering plant.—*E. C. L.* 1, Cupressus, we cannot tell which one, but probably C. sempervirens; 2, Retinospora pisifera aurea, really a form of Cupressus; 3, Pseudotsuga Douglasi, once called taxifolia; 4, Abies concolor, 5, probably the Deodar, Cedrus Deodara.—*B. B., Dunstable.* Ruellia macrantha.—*A. M., Londonderry.* 1, Statice sinuata (yellow form); 2, Statice latifolia.—*J. K., Huddersfield.* Olearea Haastii.—*Pinehurst.* 1, Rhus cotinus; 2, Abies Pinsapo; 3, Thuya gigantea. Apple next week

PEAS INJURED: *A. B. C.* No fungus is present on the pods; we believe the rusty appearance is caused by thrips.

PLUM LEAF BLISTER: *B. H. B.* The injury is caused by the Pear leaf blister mite Phytoptus piri. It is now too late to do anything this season, but to prevent recurrence next year spray when the leaf-buds are opening with a mixture consisting of one ounce of soft soap and a wineglassful of paraffin thoroughly mixed in a gallon of rainwater.

THE NUNNERY GARDENS, ISLE OF MAN.—We take note of your letter.

TOMATOS: *A. B.* Tomato rust, Cladosporium fulvum Burn the affected plants and syringe the others with weak Bordeaux mixture.

ILLUSTRATIONS.

THE FRENCH RIVIERA.

AN excursion to the French side of the Riviera, to Cannes and Antibes, where numerous old gardens are to be found, is always very interesting. The landscape differs greatly from that on the Italian side of the Riviera, east of the river Var. The Alpes Maritimes, which shelter the Italian Riviera as far as Nice, are directed northwards, and only lower mountains and hills follow the coast as far as Cannes. The west side of the Bay of Cannes is bordered by the picturesque Esterel Mountains. The coast along this strip of land is flat, and sand downs are more or less conspicuous. From the Var, as far as Antibes and Juan-les-Pins, these downs extend for a considerable tract inland, with much rough gravel, which offers only a sterile soil, on which short grasses form meagre meadows or woods of Pinus halepensis are growing. At Juan-les-Pins and the Croisette, as also along the west boundary of Cannes, the sand is of the usual fine quality. On these sandy downs Pinus Pinaster and the stone Pine, P. Pinea, grow in dense woods, and individual trees of great beauty are to be found.

Whilst the rocks of the Italian Riviera are Jurassic or of the older tertiary epoch and chiefly calcareous, the French side is, with some exceptions, a very old formation of Gneiss and Porphyry. These rocks have produced quite a different soil, rich in siliceous matter, which influences the vegetation and accounts principally for the successful cultivation of many plants. The winter temperature of that side of the Riviera is lower than it is east of the Var. The country is more exposed to north winds; nevertheless, many plants resist them as well or even better than they do at La Mortola. There is also more rain, and often we can see it raining there whilst we at La Mortola have a cloudless sky.

Cap d'Antibes is a long peninsula of calcareous rocks, reaching far out into the sea. The garden of the Villa Thuret, a botanical garden presented to the State by the widow of M. Thuret, is situated in a very sheltered spot. Professor Poirault, who succeeded M. Charles Naudin, has greatly increased the already large collection of plants. This garden is very rich in remarkable trees, and especially in Eucalyptus. There is a specimen of Jubæa spectabilis, certainly the oldest and tallest on the whole coast. Its stem is about seven metres high and 4.75m. in circumference at the bottom about 10 c. m. above the soil. One of the oldest Pritchardias I measured was 3m. in circumference. There are several fine old Cedars and some beautiful specimens of Araucaria Bidwillii. The collection of evergreen trees and shrubs is extremely rich; many botanical rarities and many very decorative species deserve mention, did space permit. Large Yucca filifera and Yucca Mazelii have been frequently photographed. There is also a collection of succulent plants, and one of bulbs and perennials. A big specimen of Opuntia tomentosa deserves special notice. It is the biggest to be found on the Riviera. The propagating beds and the new plantations contain many novelties of high interest. Everywhere it may be seen how anxious the director, Prof. Poirault, and his head gardener, Mons. Texier, are to improve this scientific garden. A visit to it is always instructive and pleasant. I found many interesting plants in flower, and gathered a rich harvest for our herbarium.

This time, however, my visit to the French Riviera took place when there were signs of rain and thunder. On July 4 and 5 heavy thunderstorms brought an enormous quantity of rain, at Marseilles 87mm., at La Mortola 70m. were measured. The storm of July 5 did great damage at Cannes and further west. At Cannes the storm was terrific. The streets were under water and covered with Platanus leaves, windows were broken, and the ships and boats lying in the port were damaged. In the gardens and along the road the trees were sadly damaged, big Eucalypti were blown down, and the telegraph and telephone wires destroyed. The railway line was also damaged, and the train and tram services were interrupted for some time. I was thus prevented from visiting some of the many fine gardens of Cannes. Many or most of them are kept up at considerable expense. The plants seem to enjoy the soil, the more so as there is no stint of manure nor of water. I saw one fine villa garden in the centre of the town which well deserves a visit. It is a typical Riviera garden in its most elaborate and expensive style. A garden of this sort is a modern form of the Rococo style, "Nature in bonds." It is sure to be found where profound knowledge and love of nature and plants are not the motive of keeping up a garden. It contains, nevertheless, many fine plants, and during the season it is sure to be admired. The magnificent Palms, groups of Bamboos, and many fine trees are striking features.

On my return to Golfe Juan I had occasion to admire quite a different style of garden. It is situated along the rocky shore between the sea and the railway on a very narrow strip of land, about one kilometre long. This garden is kept as a wild garden. Large Pines, Heaths, Cistuses, Calycotome, etc., form a dense "macchia," mixed with such exotic plants as Lotus peliorhynchus, Chorizemas, Melaleuca, etc. The whole has a charming effect. What a difference between such a garden and that at Cannes! In two places where the land is broader there is a small orchard and flower garden. In the former they cultivate a kind of Citrus (Citron gallé) from Mauritius, Anona Cherimolia was in flower, and even such delicate plants as Pandanus utilis and Piment officinalis grow well in the open.

All along the road leading from Cannes to Golfe Juan fine gardens and horticultural establishments succeed each other. Many of these gardens, however, seem sadly neglected, an eloquent proof of the decreasing interest in horticulture, which, according to a friend of mine, is due to the increasing "motoromanie." I was agreeably surprised to find in one of these gardens some fine and rare plants. Acacia vestita, of which there were several good specimens, and a single Acacia linifolia. These Acacias grow far better on this siliceous soil than on our limestone. Of the rare Hakea Victoriæ there were two old specimens, which seem to have flowered and fruited abundantly. A tall specimen of Dammara australis with a straight stem, measuring 20m. in height and 1.40m. in circumference at the base, stood isolated. The storm had broken some big branches, so I was able to collect some herbarium specimens with male flowers. I tried to impress upon the gardener the value of these rare plants and that he ought to propagate them, but if the owner of the garden shows no interest, how can his gardener be expected to do otherwise?

But, most of all, the dense Palm woods of two gardens at Golfe Juan attracted my attention. It is a pity that they have been turned by their owners into a kind of horticultural establishment. Still, much of their beauty remains. The originator of these gardens planted a tropical, or rather subtropical forest, which even now, after so many fine trees have been removed and sold, still produces an imposing effect. Tall Cocos Romanzoffiana, with their high, smooth stems, and Pritchardias form lofty columns, above which the dense green roof of the foliage hides the sky, and in the shade of which tender tree Ferns are spreading their large fronds. Many other Palms and interesting evergreen trees and shrubs, large Eucalypti, Dammara, Podocarpus, Ocotea foetens, Acacias, Banksias, etc., frame this model of a subtropical forest. We have nothing similar on this side of the Riviera, even the dense plantations of Phœnix dactylifera at Bordighera are by no means so imposing and elegant. *Alwin Berger, La Mortola, Ventimiglia, Italy.*

GUEVINA AVELLANA.

THIS evergreen tree, known also as the Chilian Nut [and as Gevuina Avellana in *Index Kewensis*], was introduced into this country and distributed by Mr Bull, who describes it as "an evergreen growing in its native country, Chili, to the height of 30 feet, and furnished with coriaceous, impari-pinnate leaves, consisting of from two to five pairs of ovate-dentate leaflets. The flowers are in simple, erect racemes, 2 inches to 4 inches in length, succeeded by globose, edible drupes enclosing almond-like seeds, which are eaten in Chili and Peru. The latter have a mild and somewhat oily taste, while the fleshy pericarp is made

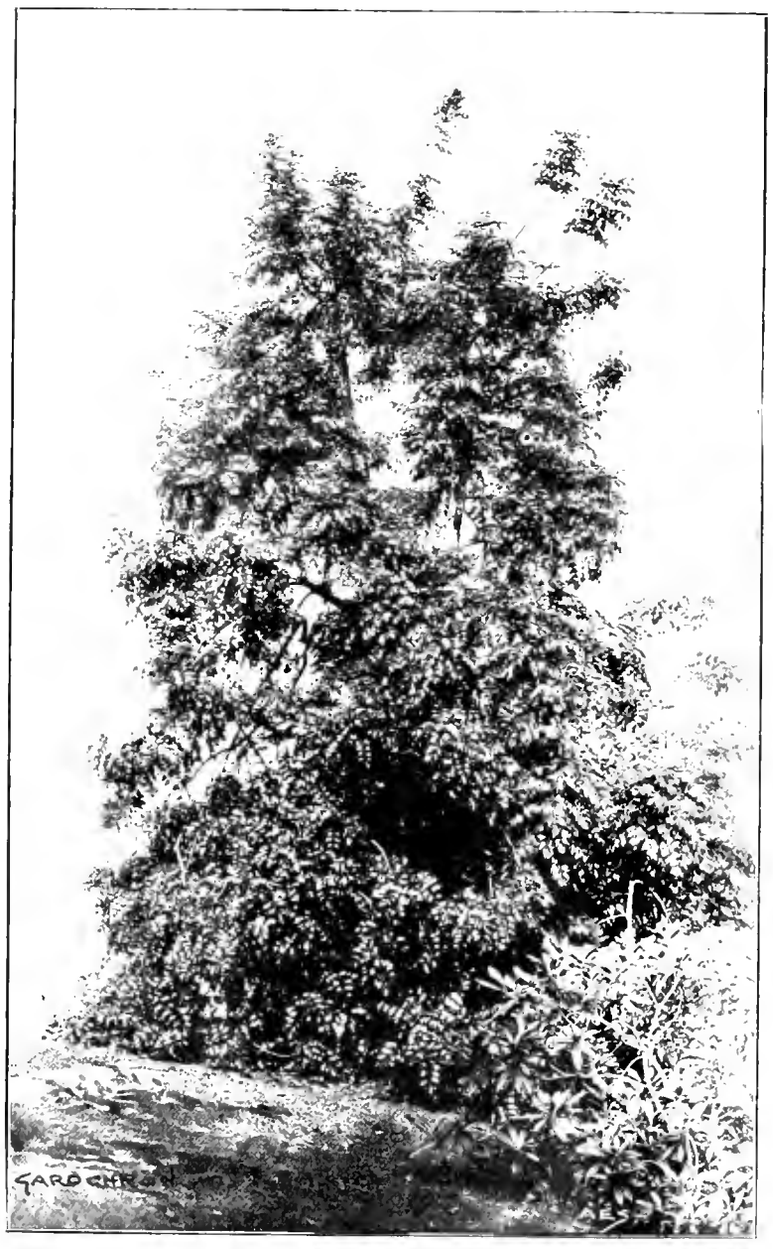

FIG. 70.—GUEVINA AVELLANA AS GROWING AT GREENWAY, DEVONSHIRE. HEIGHT 23 FEET, SPREAD OF BRANCHES 20 FEET.

a substitute for the Pomegranate. It belongs to the tribe Grevilliæ, of the natural order Proteaceæ, and has proved itself quite hardy in Devonshire, though whether it is so in any of the less favoured parts of the country we are unable to say. Anyway it is a very handsome shrub." The specimen here figured, presumably the largest in the United Kingdom, is growing at Greenway, on the banks of the Dart, the property of Mr. T. B. Bolitho. It is 23 feet in height, and at the base has a spread of 20 feet. Its age is unknown, but an old man who has worked on the estate for 42 years states that it was 10 feet or 12 feet high when he first came, so that its growth is evidently slow in the later stages. In the same garden are two other examples, one about 16 feet in height, much crowded by Rhododendrons, and another healthy plant 4 feet in height raised from a layer. In Mr. Bolitho's garden at Trewidden, Penzance, an account of which appeared in these pages a few weeks ago, is another specimen 10 feet in height, also raised from a layer, and in the same gardens are three seedlings a few inches in height. In August the flower-racemes are produced, these being 4 inches in length and holding about two dozen small ivory-white blossoms with narrow recurving petals and stamens protruding half-an-inch. These are followed by fruits about the size of marbles, at first green, then red and eventually purple. It is a very rare plant, and I know of none in the south-west except such as have been propagated by layers obtained from the plant now illustrated. As regards Mr. Bull's statement that it is quite hardy in South Devon, I may say that this spring I saw a young plant in a certain Cornish garden that had died during the winter. At Kew, growing against the wall of the herbaceous garden, is a plant labelled Guevina Avellana absolutely unlike the Greenway specimen, having entire leaves 4 inches in length and 3 inches across in place of the much-divided foliage, which is apparent even in seedlings.—*W. Fitzherbert.*

THE LILY SEASON IN SCOTLAND.

IN south-western Scotland Lilies of every description seem to have been uncommonly successful this year, the moist season manifestly suiting their requirements much better than it has suited the capricious and somewhat too susceptible Rose. I have recently had the privilege of visiting several of the finest gardens in Wigtownshire, notably those at Monreith, the exquisitely-situated residence of Sir Herbert Maxwell, a sympathetic cultivator of the finest and rarest hardy flowers and flowering trees; Dunragit, long the property of Admiral Sir John Hay, whose gardens, under the fostering care of Mrs. Cunninghame and her head gardener, Mr. Bryden, are even more attractive than they were in the Admiral's earlier days; and Castle Kennedy, famous for the spacious grounds and gardens of the Earl of Stair, which, when under the guidance of his accomplished superintendent, Mr. Cruden, I visited on a memorably bright and peaceful evening last week, were, with all their lakes and terraces and glorious coniferous trees, supremely fascinating. To visit, under serene atmospheric conditions, such a splendid collection and scenic combination as this is an education in itself, for Castle Kennedy is a veritable epitome of the flora and forestry of the world.

In all of those distinguished horticultural centres, as also at Logan House in this picturesque parish, Oriental Lilies are cultivated extensively, and with gratifying results. Sir Herbert Maxwell has always imposing specimens of Lilium giganteum in the charming shrubberies environing his brilliant flower gardens, while at Dunragit House and Castle Kennedy (as formerly at Logan) the stately and majestic Lilium auratum platyphyllum almost invariably flowers grandly, and reaches an imposing height. Last year I parted with an enormous bulb of Lilium giganteum, the great Himalayan Lily, because, after growing it patiently for at least four years from an offset, it failed to bloom. I gave it to my near neighbour, Mr. John Hill, mechanic and earnest amateur horticulturist, with whom, I am glad to say, it flowered superbly this season, adorning, with its long, funnel-shaped, ivory white, and intensely fragrant blooms, a conspicuous border in his beautiful, miniature garden, where it was the admiration of all beholders.

Lilies, in my opinion, are very conservative, and object to transplantation, unless when accompanied, as in this special instance, by an adhering portion of soil; but Lilium giganteum, doubtless in virtue of its marvellous vitality, appears to be an exception to the general rule. Plant-life, like our own mysterious physical nature, is sometimes benefited by an entire change. The Lilies that have succeeded best in my garden this year are Lilium monadelphum, var. Szovitsianum, a native of Mount Caucasus and Persia, which reached a height of nearly 9 feet, and flowered magnificently; the Siberian L. davuricum, var. incomparabile, a very dark-hued and effective variety; the satiny-white and richly fragrant Madonna Lily—Lilium candidum—which in some gardens I could mention has been almost ruined by an insidious disease; Lilium pardalinum, and its more vigorous and prolific derivative, Lilium Burbanki, which resembles it much too closely to be perfectly distinct; and Lilium chalcedonicum, the lustrous "Scarlet Martagon." Lilium auratum is exceedingly promising, but it is considerably later in unfolding its Oriental splendours here than on the sunny terraces at Lochinch Castle.

Lilium speciosum, one of the loveliest and most refinedly fragrant of all Eastern Lilies, invariably flowers impressively here, the only exception being the variety of comparatively

recent introduction entitled "magnificum," which, if my own experience of its characteristics is any criterion, seems to be lacking in vitality and floral capability. I cannot doubt however, that when more strongly established it will, like its predecessors, greatly improve.

The various fascinating forms of Lilium longiflorum are usually adequately successful the first season, but they are not enduring. There is, ere long, too great a multiplication of minute and utterly impotent bulbs, and rapid deterioration is the inevitable and lamentable result. *David R. Williamson, Wigtownshire, August 28.*

MODERN BOTANY.

The following extracts are taken from Prof. F. W. Oliver's address to the Botanical Section of the British Association at its York meeting, not to mention others, were continually bringing these results before societies, writing about them in the journals, and translating books. But the thing never caught on—it would have been surprising if it had. You may write and talk to your contemporaries to your heart's content, and leave no lasting impression. The schools were not ready. No movement of the sort could take root without the means of enlisting the sympathies of the rising generation. It was only in the 'seventies that effective steps were taken to place botany on the higher platform; and the service rendered in this connection by Thiselton Dyer and Vines is within the knowledge of us all. Like the former in London, so the latter at Cambridge aroused great enthusiasm by his admirable courses of lectures. Great service, too, was rendered by the Clarendon Press, which diffused excellent translations of the best Continental text-books—a policy which it still pursues with unabated vigour, though the need of them is, I hope, less urgent now than formerly. Already at the time of the last meeting in York (1881) a select band of Englishmen were at work upon original investigations of the modern kind. The individuals who formed this little group of pioneers in their turn influenced their pupils, and so the movement spread and grew. It would be premature to enter fully into this phase of the movement, so I will pass on with the remark that modern botany was singularly fortunate in its early exponents.

"Whenever the history of botany in England comes to be written, one very important event will have to be chronicled. This is the foundation of the Jodrell Laboratory at Kew, which dates from the year 1876. Hidden away in a corner of the Gardens this unpretentious appendage of the Kew establishment has played a leading part in the work of the last twenty-five years. Here you were free to pursue your investigations with the whole resources of the Gardens at your command. I suppose there is hardly a botanist in the country who has not at some time or other availed himself of these facilities, and who does not cherish the happiest memories of the time he may have spent there. Certainly Jodrell displayed rare sagacity in his benefactions, which included, in addition to the laboratory that bears his name, the endowments of the Chairs of Animal Physiology and Zoology at University College, London.

"Sir William Thiselton Dyer, who has so recently retired from the Directorship of Kew, had every means of knowing that his happy inspiration of founding a laboratory at Kew was a most fertile one. It would not be surprising if the future were to show that of the many changes inaugurated during his period of service this departure should prove by far the most fruitful.

"Another incident belonging to the early days ought not to be overlooked. I refer to the notable concourse of Continental and American botanists at the Manchester meeting of the British Association in 1877. The genuine interest which they evinced in our budding efforts and the friendly encouragement extended to us on that occasion certainly left an abiding impression and cheered us on our way.

"We are not forgetful of our obligations. We regard them in the light of a sort of funded debt on which it is at once a pleasure and a duty to pay interest. The dividends, I believe, are steadily increasing—a happy result which I am confident will be maintained.

"But I should be lacking in my duty if I permit the impression to remain that botany is anything but a sturdy and natural growth among us. The awakening, no doubt, came late, and at first we were influenced from without in the subject-matter of our investigations. But many lines of work have gradually opened out, whilst fruitful new departures and important advances have not been wanting. We still lean a little heavily on the morphological side, and our most

FIG. 71.—SINGLE GROWTH OF GUEVINA AVELLANA.
(For text see page 174.)

unfortunately held concurrently with the Hybridisation Conference in London.—

"The period of twenty-five years that has elapsed since the British Association last met in this city all but includes the rise of modern botany in this country. During the middle decades of last century our botanists were preoccupied with arranging and describing the countless collections of new plants that poured in from every quarter of an expanding empire. The methods inculcated by Linnæus and the other great taxonomists of the eighteenth century had taken deep root with us and choked out all other influences. Schleiden's 'Principles of Botany,' which marked a great awakening elsewhere, failed to arouse us. The greats results of Von Mohl, Hofmeister, Nageli, and so many other notable workers, which practically transformed botany, were at first without visible effect.

"It was not that we were lacking in men capable of appreciating the newer work. Henfrey, Dr. Lankester (the father of our president),

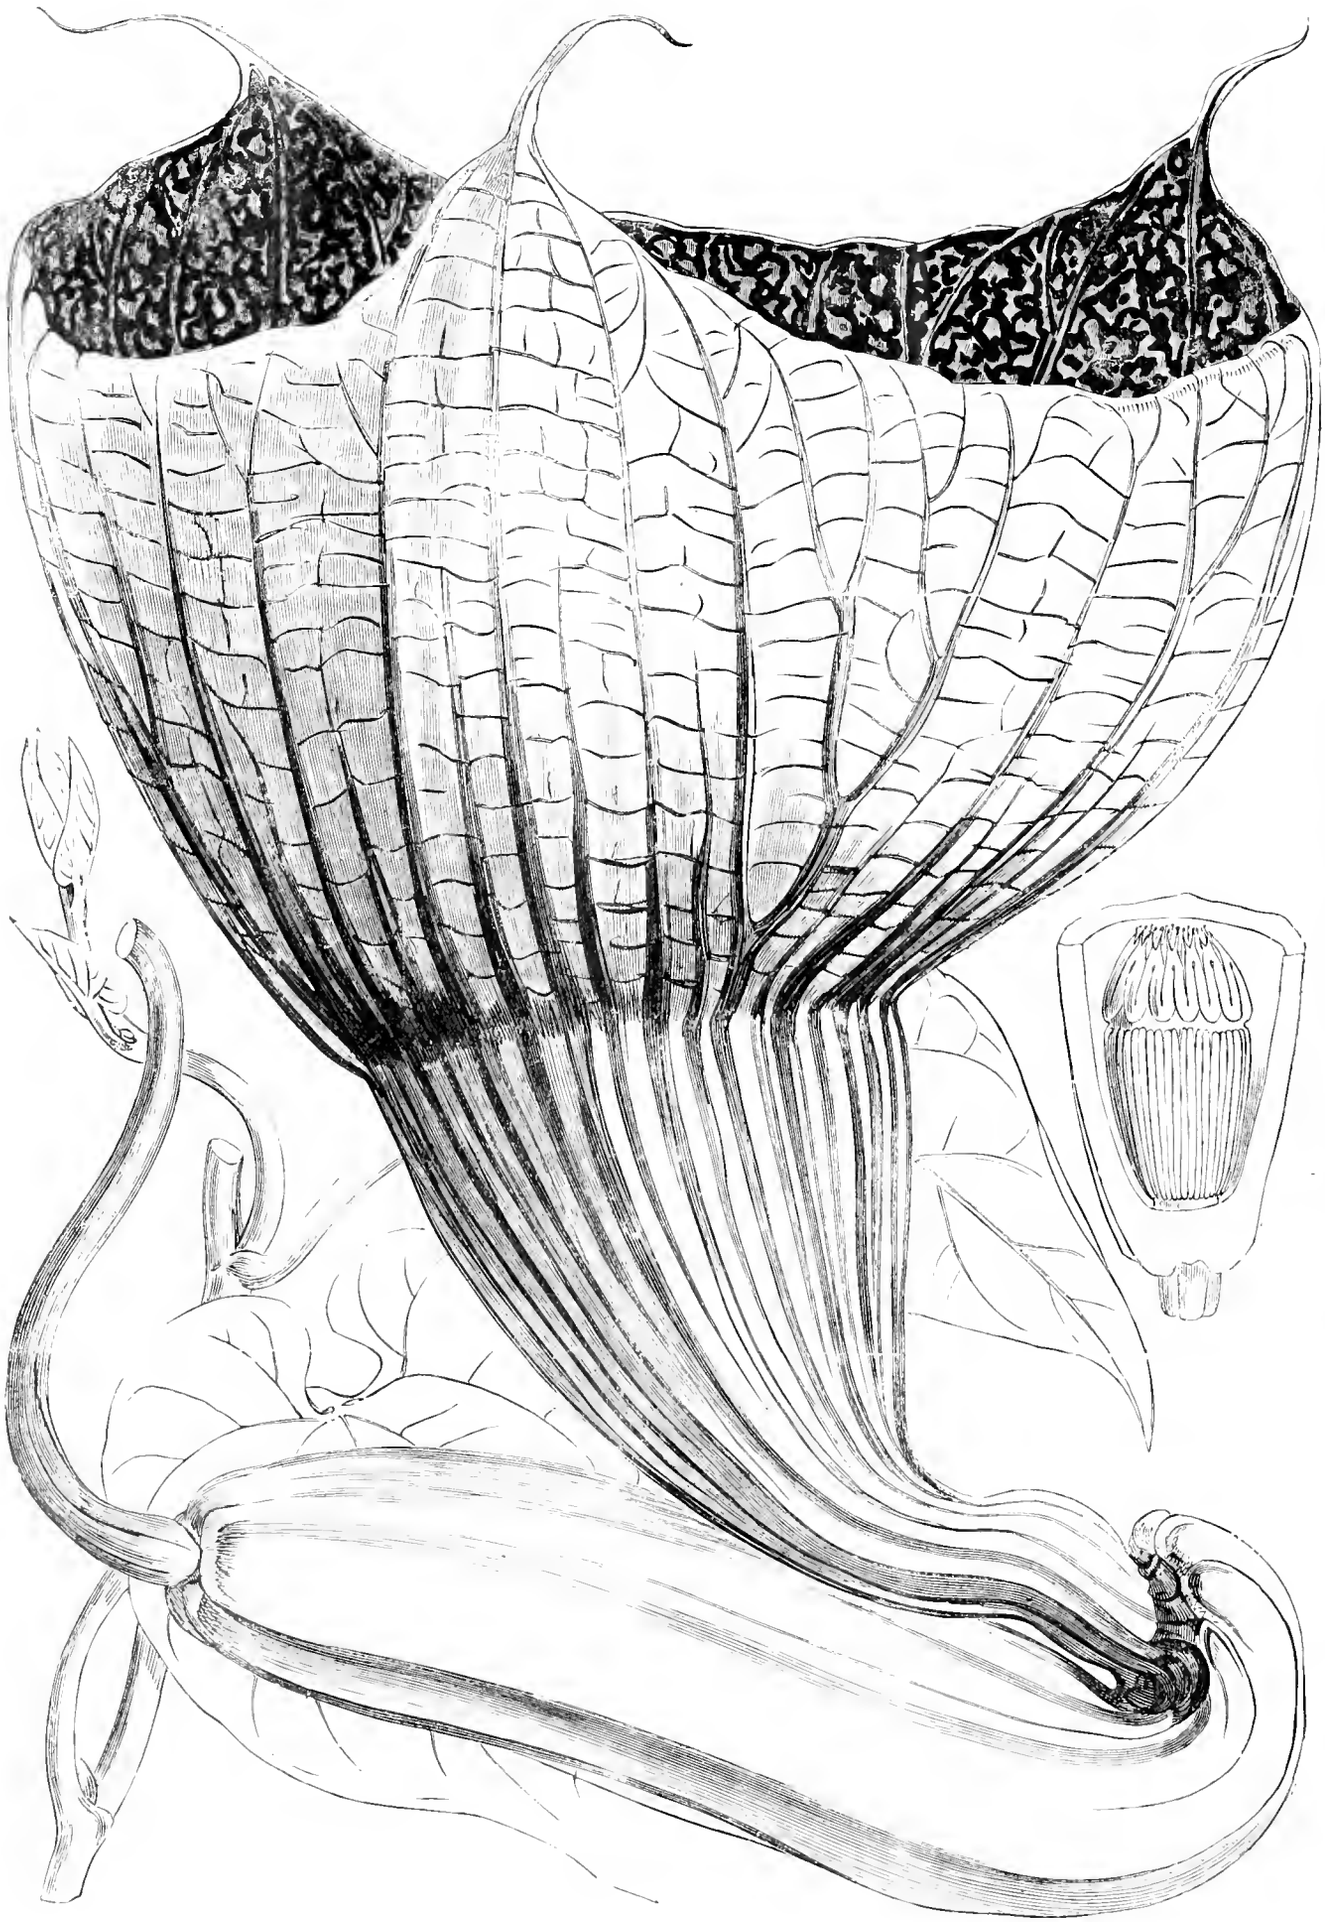

FIG. 72.—ARISTOLOCHIA GOLDIEANA WHICH FLOWERED LAST MONTH IN THE LIVERPOOL BOTANIC GARDEN. (REDUCED ONE HALF.)

For text see page 177.)

urgent need lies in the direction of physiology. As chemists and physicists realise more fully the possibilities of the 'botanical hinterland,' one may expect the conventional frontier to become obliterated. As Mr. F. F. Blackman has pointed out in a recent interesting contribution,* the chemist's point of view has undergone a change with the growth of the science of physical chemistry, and is now much more in line with that of the biologist than was formerly the case. This natural passage from the problems of the one to those of the other should be the means of attracting into our body recruits possessing the necessary chemical equipment to attack physiological problems.

"As the position gains strength on the physiological side, it will become possible to render more effective service to agriculture and other branches of economic botany.

"This is of importance for a variety of reasons. Among others it will bring public support and recognition, which will be all for the good, and it will provide an outlet for our students. It will also afford unrivalled opportunities for experiments on the large scale. Even should economic conditions, which compel us to import every vegetable product, continue to prevail in this country, this will not be so in the Colonies. As time goes on, one may reasonably expect an increasing demand for trained botanists, ready to turn their hands to a great variety of economic problems.

"From this rough sketch we see that the prevailing school of botany has arisen very independently of that which preceded it. The distinction—their efficiency probably has never been greater than at the present time. But the effort involved in their construction and upkeep is altogether disproportionate to any service to which they are put. Work, of course, comes out of them; it is no question of the devotion or ability of individuals. It is the general position, the isolation of systematic botany, to which attention should be directed with a view to its alleviation.

"If things are left to take their course there is the fear of atrophy through disuse. The operation of the ordinary economic laws will no doubt serve to fill vacancies on the staff as they arise, but the best men will be reluctant to enter. Of course, the pendulum may begin to swing the other way, though no indication of such a change is yet apparent."

(To be continued.)

* 'Incipient Vitality,' *New Phyt. Cont.*, v. i. v., p. 22.

FIG. 73.—SALVIA DICHROA: FLOWERS LAVENDER-COLOURED, AND WHITE.

ARISTOLOCHIA GOLDIEANA.

THIS remarkable species was flowering in the stove in the Liverpool Botanic Gardens on August 10. It is a native of Old Calabar, West Africa, where it was discovered by Mr. Thompson in 1864, and it flowered in the Glasgow Botanic Garden in July, 1867. The species has blossomed several times in this country, but only on very rare occasions. It flowered in the Royal Gardens, Kew, in April, 1891, but since that date it has failed to develop a single blossom in those gardens. A. Goldieana differs from all other members of the genus in its method of flowering, which is on the young growth and when it is only a few inches in length. The annual growths are produced from a swollen, woody rootstock. The development of the shoot is arrested until the flower fades, after which it rapidly elongates, making a growth 4 to 6 inches in length, which bears large cordate-acuminate leaves. The flower is borne on a stout pedicel some 6 inches in length: it is of a brown-red colour mottled with yellow. The distended throat is streaked with both lighter red and cream-white lines. In form the flower is somewhat triangular and has a diameter of nearly a foot. Measured from the pedicel to the tip of the bloom our flower was 1 foot 7 inches. A. Goldieana is figured in the *Bot. Mag.*, t. 5,672, and was described in the *Gardeners' Chronicle* as far back as November 9, 1867, p. 1,143.

One very curious fact in connection with this species is that it produces flower-buds almost every year, yet rarely do they mature. It is usually a battle for supremacy between the growth and the bud, generally the growth is victorious and the bud withers and falls. Our plant that flowered was kept quite dry at the roots until after the growth had commenced, when the apex of the shoot immediately above a bud was removed and all laterals were pinched out. After the flower-bud was swollen and of a reddish-brown colour the plant was thoroughly watered and afterwards kept fairly moist until the flower was fully developed, which in the present instance took five weeks. The last time this plant flowered at Liverpool was 14 years ago. *W. H., Liverpool Botanic Gardens.*

SALVIA DICHROA.

THIS noble Salvia is evidently very rare in cultivation, since, although it is stated in Nicholson's *Dictionary of Gardening* to have been introduced in 1871, no mention of it is to be found in the volumes of the horticultural Press for the past 25 years that I have searched. The plant was originally given me by Lord Walsingham under the name of Salvia tingitana, but, upon his submitting a flower spike and foliage to the authorities at Kew, they decided that its correct name was S. dichroa. Nicholson gives its height as from 2 feet to 3 feet, but the plant portrayed in the illustration (fig. 73) this year attained a height of 9 feet 6 inches, with a spread of 6 feet at the base. The flower-spikes are about 3 feet in length, and some 9 inches of the spike is covered with open flowers at the same time, but as the lower blossoms fade the upper ones expand, so that the blooming period is prolonged. The leaves are about 1 foot in length and the same in breadth, and are very deeply cut, being corrugated and covered with hairs on the lower side. A large plant bearing hundreds of flower-spikes is a grand sight when in full bloom, and in July is quite the glory of the garden. The individual flowers are of lavender-purple shade, the middle lobe of the lip being white. On a flower-spike recently cut there were 48 expanded and partially expanded blooms, while the total number of flowers borne on the spike was 175. Salvia dichroa is a native of the Atlas Mountains in North Africa, and the plant is therefore,

possibly, of doubtful hardiness, but in South Devon has never been harmed during the winter even though totally unprotected. Towards the end of August the leaves and stems wither and die, the plants throwing up new growth in the autumn. I am under the impression that this Salvia is not yet in commerce. *S. W. Fitzherbert, South Devon.*

NOTICES OF BOOKS.

JUGENDFORMEN UND BLÜTHENREIFE IM PFLANZENREICH: Juvenile Forms and Flowering Age in the Vegetable Kingdom. By Dr. L. Diels, private tutor in the University, Berlin. Published by Gebruder Bornträger, Dessauerstraase, 11, Berlin, S.W.

The not uncommon instances met with in the Old World and in Australia of the early flowering and dwarfed growth in trees and other kinds of vegetation, whilst in the same locality, and under different conditions of soil, exposure, water supply, &c., the same species may be observed reaching their fullest development, and flowering and fruiting when only of mature age, have afforded the author much matter for speculation as to the causes of these abnormalities, but without arriving at any satisfactory conclusions. He had ample opportunity of noting such occurrences during a lengthened sojourn in the western and other parts of Australia. The Flora of that continent is famous for the large number of its species, and the constant exchange of the factors which have an influence in altering the forms of the vegetation, and the alterations present themselves in sharply-defined features.

Instances of the relation of growth to reproductive maturity, and of youthful forms combined with ability to produce flowers and seeds, are everywhere met with. Since his return to Europe the author has looked up the literature of the subject and collected facts, the latter forming a far-reaching collection and throwing a new light on the manifold variations in plants. The author does not make any attempt to give a complete presentment of these cases, but merely takes typical examples of the many-sidedness observed, treating them briefly or otherwise, according to the nature and value of the object, and omitting all mention of matters of doubtful significance.

The development of a plant from the germination of the seed onwards runs through many phases that show themselves in the varied forms of the different organs. The final phase of this vegetative activity being the formation of the spore or seed, maturity is indissolubly dependent on vegetative development, and the end, which is due to "internal causes," the plant is bound to reach. Until quite recent times these views were unquestioned, and are those generally held, especially in the case of flowering plants. These views are now the subject of much discussion, and it has become necessary to obtain a clearer knowledge of all that is known or can be known about the formation of the floral organs. A tolerably complete picture of the more important points is afforded by Moebius in his "Baitragen zur Lehre von der Fortpflanzen der Gewachse," Jena 1897, see pp. 78-134.

Dr. Diels takes account of the action of sunlight, climate, aerial moisture, dryness of the soil, lack of plant nutriment in the last-named; and a list of plants is given which suffer through lack of favouring conditions. One striking example given is Abies excelsa, which usually flowers in its 30th-40th year; but on hungry soil came to flowering age in its 15th year, and setting its seeds abundantly in its 50th year. This is an instance of dryness of the soil producing abnormally early maturity, poverty of the soil having a similar effect. Temperature has great influence in the same direction, cold directly and indirectly through lessening the amount of available nutriment and moisture in the soil. A number of instances are given of the early flowering of Coniferæ, Bamboos, Palms, Quercus, Roses, Ailanthus, Rhus cotinus, Banksia, and Eucalyptus, which flower early or late, accordingly as the soil and other conditions are unfavourable or otherwise. Leptospermum ellipticum was named, which commonly grows to 2 yards in height, but which on bare soil only reached from 6-8 inches; and Eucalyptus marginata, the most important timber tree of West Australia, which does not succeed if the rainfall is less than .75c.m. annually. But there are exceptions. On the Stirling range of mountains there were found by Dr. Pritzell trees of 90 feet in height, and also shrubby forms of the same species (E. occidentalis) scarcely 3 feet in height.

The author's researches were not confined to the plants of Australia, but extended to water and swamp species of Europe, of especial interest being his remarks and those of Glück in his "Untersuchungen uber Wasser und Sumpf Gerwächse." A list of European plants is given which flower early under certain natural conditions, such as scanty nutrition, the shortening of the growth period, and exposure to strong light.

From such causes arise the lowly forms of Ranunculus pygmæus in the neighbourhood of the snow line—real examples of "Hunger forms." And similarly the formation of spores in Marsilia and Bidens.

Changes in the forms of leaves of Hakea, Pittosporum, Banksia, and in fronds of Ferns, &c., are noted. The author's conclusions are that arrested vegetative growth will not account for all the alterations that occur in the form and flowering age of plants; and that the reproductive stage is not inseparably connected with any certain stage of vegetative development. There is a certain minimum in the life of a plant which must be reached, and that exceeded, there is a wide zone for variation of the flowering stage. Heterogenetic influences are brought to bear in some instances; variations, exogenic in great part with cryptogams as with flowering plants; but of these we know but little.

Although the instances of early flowering, &c., are of interest from the great variety of plants observed in many parts of the world, these do not seem to add much to our knowledge. The effects of occasional drought and constant dryness in the soil; a restricted area from which the roots can draw nutriment; lack of plant food; crowded state of a plantation of trees or other plants are matters well known to gardeners and foresters, and this knowledge is sometimes acted upon from intent. We all know what occurs when a young Pine-apple plant is allowed to get pot-bound in a small pot; when a fruit tree's roots are brought up from a rich sub-soil and planted shallow; or by working a variety on a dwarfing stock and thus restricting the feeding area of the root system of the plant; when seeds of Broad Beans are sown on poor land; also pickling Onions; when Willows for basket-making are planted on dry soil; when Melons are planted on thin beds of soil.

The gradual dwarfing of vegetation as we approach the poles, or the summit of high mountains, is another well-known fact. The effect of exposure to strong winds can be seen at most seaside places and on hill-sides. Remove, however, the causes of abnormality, and there is a return to larger and longer continued growth and a retarded maturity, and, as a consequence, flowering likewise.

The Week's Work.

PLANTS UNDER GLASS.

By B. CROMWELL, Gardener to T. SUTTON TIMMIS, Esq., Cleveley, Allerton, Liverpool.

Chrysanthemums which are being grown for the production of large blooms for exhibition or home decoration will now have reached an important stage, and encouragement should be given them by top-dressing for the purpose of increasing root action, and also by applying stimulants afterwards. For top-dressing purposes a mixture of two parts loam to one pound of animal manure is at all times a safe mixture. If clear soot-water be applied about twice each week it will soon improve the colour of the foliage of pale-looking plants, and an occasional syringing of the foliage with soot-water, if perfectly clear, will prove beneficial in keeping the plants free from red spider. Sheep droppings gathered fresh from the fields is of great value, and a stimulating liquid may be prepared from such manure by placing it in a bag to prevent it mixing with the water, which otherwise would form into a thick liquid; and if applied to the plants in this form it would leave a sediment on the top of the soil and thereby seal up the air and close the water passages. The bag should be moved about in the water each day and the virtues of the manure will be abstracted. A word of caution is necessary, even, in the matter of applying stimulants to Chrysanthemums, for although moisture-loving subjects and gross feeders, they suffer from any stagnation, or more moisture at the roots than can be assimilated. The perfectly safe practice is to apply liquid stimulants in a weak state at frequent intervals, and changing occasionally the kind of plant food applied will prove beneficial. The degree of constitutional vigour in each plant will be a guide to observant cultivators how to administer stimulants successfully. Should the present hot weather continue, plants with their buds just set should be very slightly sprayed over towards the evening.

General Remarks.—Thin out the superfluous growths of stove and greenhouse climbers. Decrease the amount of shading used as much as possible, so that the plants will mature and ripen their wood; this especially applies to Allamandas, Bougainvilleas, Dipladenias, Ixoras, and other stove and greenhouse plants which need this timely thinning out to ensure their successful flowering. Admit air freely during the day and leave the roof ventilators open a little during the night; reduce slightly the atmospheric moisture in these structures. Poinsettias in pits or frames will better mature their growths if the pit-lights are removed entirely for two or three hours during the hottest part of the day. Let Cyclamens, Primulas, and Cinerarias be fully exposed to the night dews by removing the lights in the evening.

FRUITS UNDER GLASS.

By T. W. BIRKINSHAW, Gardener to Lt.-Col. Sir CHAS. HAMILTON, Bart., Hatley Park, Bedfordshire.

Strawberries.—Plants that were put into the final pots early will now be growing freely. Place the plants thinly, giving each plenty of room so that they will be the better exposed to the rays of the sun. Those growing in 5-inch pots should be given weak doses of liquid-manure about twice each week. One of the most important items is to get the crowns well matured before the days become very short, and therefore stimulants must not be applied in excess or sappy growths will be the result. Pot up late runners at once, putting them in the shade for a few days until they take hold of the new soil. Remove runners from these young plants as soon as they appear and keep the pots free from weeds. Syringe the plants with water after the sun has gone down in the afternoon. The plants should be kept to one crown, removing any small ones as they form.

Tomatos are usually required through all the seasons of the year, therefore get a house in readiness for the reception of plants now growing in pots out of doors, and which must be removed indoors when the weather turns cold and wet. If the plants have set any fruits, a surface dressing of loam and bone-meal should be applied to the roots. Keep all side growths pinched out, and water the plants with care. Tomato plants intended for fruiting in winter should be kept well up to the light, and a free circulation of air should be allowed in the house when the weather is favourable. Move the plants into the final pots as they become ready, so that they may get well established before there is cold weather. White fly may be destroyed by fumigations.

Cucumbers.—Plants that are still bearing fruit, and showing signs of exhaustion, should be given a rich top-dressing of loam and horse-manure, with frequent applications of liquid-manure. Close the structures early in the day to conserve the sun-heat, and let there be plenty of moisture in the house. The present is a good time to sow a pinch of seed of such a variety as Telegraph, which is still a very reliable sort. Afterwards get a house

ready for them by washing all the wood-work and lining the walls. Prepare a hot-bed of long litter, and place small hillocks of loam and leaf soil upon it, and when the soil is thoroughly warmed through the plants may be planted in these. Apply a liberal amount of ventilation on all favourable occasions. Regulate the growths of plants that are still growing in pits and frames, cutting away any old leaves to make room for the extension of young laterals, which will still continue to yield a few fruits. Place fresh linings of litter to the frames where the bottom heat is on the wane. If there is an appearance of mildew on the foliage, apply a dusting of flowers of sulphur.

THE FLOWER GARDEN.

By HUGH A. PETTIGREW, Gardener to the Earl of PLYMOUTH, St. Fagan's Castle, Glamorganshire.

Naturalizing Bulbs.—For growing in the deep shade of trees there is no bulb better than the Wood Hyacinth or Bluebell (Scilla nutans). Many an uninteresting spot could be converted into a charming picture in spring by the free use of this flower, which adapts itself readily to such conditions, and increases rapidly. For similar places or for open glades the Grape Hyacinth (Muscari botryoides) has also much to recommend it; particularly the variety "Heavenly Blue," which should be planted for its pleasing colour, which, when seen in large sheets in combination with Daffodils and Tulips in the grass, is very effective. In the deep shade and shelter of trees colonies of hardy Cyclamens might be successfully made. Before planting the tubers the ground should be improved by manuring and the addition of fresh soil, remembering also that, though the plants enjoy moisture at the root, they cannot thrive on wet, sodden land, therefore good drainage is necessary. Unlike Cyclamen persicum the tubers of all the hardy species must be planted fairly deep in the soil. The Ivy-leaved Cyclamen (C. hederæfolium) is one of the best for naturalising, because of its pretty foliage. It is attractive during the winter and spring months, while in the autumn its flowers, which are usually borne profusely, are delicately beautiful. The round-leaved Cyclamen (C. Coum) is a splendid bulb for naturalising in the shade of trees, and also C. europeum, which is distinctly fragrant. Camassia esculenta, a North American plant, is a splendid bulb for planting in the open ground. A bold group in full bloom in June is a fine sight with the deep-blue flowers rising well above the grass. It thrives best in a moist situation, and in selecting a habitat for it in some deep, rich soil, it should be borne in mind that the grass about it cannot be cut until late in summer. Such plants as Crocuses, Narcissi, and Tulips ripen off comparatively early, but not the Camassia. There is another bulb which should be naturalised in conjunction with Snowdrops, Chionodoxa, and the Siberian Squill, to which it would form a charming and attractive addition in a semi-wild state in pleasure grounds and woodland walks exposed to the sun; this plant is the delicately-coloured Triteleia uniflora odorata. The flowers open at sunrise and in bright weather are very beautiful and fragrant. It is perfectly hardy, is capable of growing in almost any soil, and being cheap can easily be procured in large quantities.

THE KITCHEN GARDEN.

By J. GIBSON, Gardener to His Grace the Duke of PORTLAND, Welbeck Abbey, Notts.

Young Carrots.—Young Carrots raised from seed sown last month will be having a very trying time on light soils during the present tropical weather. It is important that growth should not be arrested by this cause, otherwise when rain comes the roots will split and become of very little value. Apply a mulch of horse droppings or short manure, and afford the plants liberal supplies of water. Green fly is most likely to make its appearance on the foliage, but may be easily arrested by syringing several times with soft soap and water, in which a little paraffin has been mixed.

Mushroom Beds.—Continue to collect material for making beds to provide a supply of Mushrooms in late autumn. The material composing any beds now ready for making up should be on the moist side in order to counteract the present dry condition of the atmosphere. Add a little loam and some half-decayed leaves to the droppings. This will economise the droppings and be also of service to the crop. Extra beds should be formed indoors, as there is little prospect in many parts of the country of obtaining Mushrooms in autumn from the fields, the drought being so severe.

Frame Cucumbers in pits and frames, and still bearing fruits should be given a final top-dressing and a general freshening up of the beds. Thin out the growth if this is excessive and shade the frames slightly, keeping the atmosphere rather close to cause fresh and rapid growth.

Gherkins being now plentiful, they should be made use of for pickling when sufficient can be had at a time for the purpose. Gather the fruits whilst still of small and uniform size.

Protecting Late Crops.—Make preparations for protecting such crops as Marrows, French Beans, &c., by having some temporary framework erected so that no trouble may arise when, after a change in the weather, there may be indications of frost. Very often there are two or three successive frosts very early, and these are followed by a period of open weather.

Seed Saving.—Those who are desirous of keeping the best stocks of vegetables should endeavour to save a few selected pods of Peas, French and Runner Beans, &c., annually, so that eventually an improvement may be brought about in each kind. Save just a few of each, selecting only the very best types.

THE HARDY FRUIT GARDEN.

By W. A. COOK, Gardener to Sir EDMUND G. LODER, Bart., Leonardslee, Sussex.

Raspberries.—The old canes should now be cut down close to the ground, for they will be of no further service to the plants, and the young rods will receive the benefit of more light and air, which will be necessary to ripen them thoroughly. The Raspberry needs much moisture, therefore, if the stools are suffering from drought, afford them a supply of liquid at their roots and then apply some light mulching, which measures should suffice for the season. Raspberries require a change of soil occasionally, and it is a mistake to allow the beds to remain continuously in one position. If a new plantation is contemplated, a portion only of the old bed should be destroyed, for in re-making or renovating a plantation the work should be spread over several years so that the supply of fruits will not be discontinued. The ground selected for planting should be deeply trenched, and any old soil from the hot bed or potting-shed refuse, &c., can be incorporated during the process and will serve better than a lot of rank manure, which is not necessary for Raspberries when they are newly planted. The varieties to plant should include those which thrive best in the particular locality, but other newer kinds that have a good reputation may be allowed a trial. The best varieties for this district and also for that part of Surrey with which I am acquainted, viz., the Croydon neighbourhood, include Baumforth Seedling, which is an improved Northumberland Fillbasket; Hornet, a large and good flavoured variety; Norwich Wonder, one of the best Raspberries with all the qualities of a perfect fruit; Superlative, a very heavy cropper; Carter's Prolific, a good fruit and a free bearer, and, for autumn, use Belle de Fontenay.

Wasps have become very troublesome this season. All the nests of these pests should be destroyed as far as is possible. Bottles containing sweetened ale or beer should be hung among the fruit trees, and many hundreds will be caught by such means—I have tried several wasp preparations, but found none really effectual. The bottle should have a wide neck or mouth, so that the entry of the wasps will be quite easy. The traps should be emptied often or many will escape. Apple "Wealthy" should be protected early with tiffany or hexagon wasp-proof netting, for it is a great favourite with these pests. The temperature here on August 31 was 90° in the shade and 132° in the sun.

Early Apples should be gathered as soon as they are ready, but not before, or the flavour will be poor, and in a short time the fruit will shrivel. Red Astrachan, Worcester Pearmain, Lady Sudeley and Quarrenden will all be ready for harvesting and placing in the fruit room.

The Fruit Room.—This structure, if properly made, will be cool in summer and frost-proof in winter; the roof should be composed of a good thickness of either heather, reeds, or ordinary straw thatch, but the last-named is not nearly so lasting as either of the other materials. A span-roofed structure, such as is figured in the *Gardeners' Chronicle*, October 17, 1885, will be found best. The doors should be double and the windows be covered with perforated zinc, which will allow them to open wide, and it will keep out both flies and wasps. This kind of structure proves both cool and dry, and is thoroughly efficient for storing and keeping fruits.

Cordon-trained Trees must still be watered, especially those in districts where no rain has fallen and where they are trained on warm walls or growing on light soils. If this is not done the fruits cannot be expected to thoroughly develop, nor will the trees build up buds sufficiently strong for next year's supply. The present hot weather is a very anxious time for hardy fruit-growers, but no reasonable means should be spared to bring about the best results, as we have only about another six weeks before the bulk of the fruit will be stored.

Strawberries.—Attend to the necessary watering of newly-planted Strawberries, for where this is done the plants will make good progress.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower to Sir TREVOR LAWRENCE, Bart., Burford, Surrey.

Shading and Ventilation.—The shading with flour and water which was put on the glass of some of the houses, as advised in my calendar for April 28, is now gradually wearing off, thus allowing an increase of light to the plants, which at this season is of the greatest benefit to them. After this date there will be no need to use the blinds on the Dendrobium or Mexican houses, but during the middle of the day when the sun is hot plenty of ventilation should be afforded. Let both houses be closed early in the afternoon to retain as much sun-heat as is possible. The Cattleya house, which at Burford runs from north to south, will also need less shading with the blinds, those on the east side are not let down before 10 a.m., and are pulled up again by 12.30. At that time those on the west side are let down, and these are again removed soon after 3 p.m. All the plants in this house require much fresh air at this season, and together with the increased amount of sunlight this will cause the plants to dry more quickly at the root, thereby allowing more water to be given to them. Such treatment, if carried out with discretion, will enable the pseudo-bulbs to become plump, and the leaves of a firm leathery texture. In this house there are always some plants which are in various stages of growth, some even are only now commencing to grow, but the same treatment will benefit them also. When removing the blinds in the afternoon, only the top ventilators are closed, while those on the ground-line are left wide open, a "chink" of air, according to the weather outside, is admitted again at the top during the evening, and allowed to remain so during the night, the atmospheric temperature of the house thus falling to about 65° by the morning. The deciduous Calanthes also like the subdued sunlight, and with the Dendrobiums will not require the blind again this season. Examine the plants every morning and thoroughly water every plant that is dry. Do not allow these Calanthes to stand too closely together, but arrange them so that plenty of light may reach the new pseudo-bulbs, and that air may circulate freely around them. The Phalænopsis are producing many new leaves, and at this season require much sun-heat, which may easily be afforded if the glass is stippled, by removing the blind several hours before the sun ceases to shine on the roof. The bottom ventilators in this house are always closed, air being admitted in more or less degree through the roof ventilators. The interm diate and Odontoglossum houses having a cooler atmosphere, it is necessary to shade them rather more than others, but the blinds should not be kept down unless the heat from the sun is likely to raise the atmospheric temperature higher than what is considered advisable.

Canes of Dendrobium Wardianum that are finishing their growth in the cooler divisions, may, as soon as the terminal leaf is completed, be removed to a sunny position in a cool, well-ventilated structure. With the extra exposure the leaves will soon commence to change colour, when less water must be applied to the roots, discontinuing the supply altogether after the leaves have fallen. If the pseudo-bulbs are properly matured in this manner, they will not be likely to shrivel until they are in bloom, but should they show signs of doing so while the plants are in a dormant condition a little water may be afforded occasionally.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication *as well as specimens and plants for naming, should be addressed to the* **EDITOR, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY *of the paper, and as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

APPOINTMENTS FOR THE ENSUING WEEK.

SATURDAY,	Sept. 8	Dutch Gardeners' Soc. meets at Richmond.
MONDAY,	Sept. 10	United Hort. Ben. & Prov. Soc. Com. meets.
TUESDAY,	Sept. 11	Roy. Hort. Soc. Comms. meet.
WEDNESDAY,	Sept. 12	Roy. Caledonian Hort. Soc. Show in Waverley Market, Edinburgh (2 days). Meeting of British Gardeners' Association at Edinburgh.
THURSDAY,	Sept. 13	York Dahlia Show (2 days).
SATURDAY,	Sept. 15	German Gard. Soc. meets.

AVERAGE TEMPERATURE for the ensuing week, deduced from observations of Forty-three Years at Chiswick—58·5°.

ACTUAL TEMPERATURES:—

LONDON.—*Wednesday, September 5* (6 P.M.): Max. 73°; Min. 54

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London. *Thursday, September 6* (10 A.M.): Bar., 30·1, Temp., 67°, Weather—Fine.

PROVINCES.—*Wednesday, September 5* (6 P.M.): Max. 67° Guildford; Min. 59 West Coast of England.

SALES.

MONDAY—

Sale of Bulbs at Stevens' Rooms, King Street, Covent Garden, at 12.30 (also Wednesday).

Dutch Bulbs, at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 10.30, and every day except Saturday.

Twenty-first Annual Sale of Pot plants, at Dyson's Lane Nurseries, Upper Edmonton, by order of Messrs. H. B. May & Sons, by Protheroe & Morris, at 11.

TUESDAY—

Annual Trade Sale of Winter-blooming Heaths, &c., at Burnt Ash Road Nurseries, Lee, S.E., by order of Messrs. B. Mailer & Sons, by Protheroe & Morris, at 11.

WEDNESDAY—

Annual Trade Sale of Winter-flowering and other plants, at the Nurseries, South Woodford, by order of Mr. John Fraser, by Protheroe & Morris, at 11.

THURSDAY—

Thirty-eighth Annual Trade Sale of Stove and Greenhouse Plants at Brunswick Nurseries, Enfield Highway, by order of Mr. J. H. Thompson, jun., by Protheroe & Morris, at 11.

Twenty-fifth Annual Trade Sale of Winter-blooming Heaths, &c., at the Longland Nursery, Sidcup, S.E., by order of Messrs. H. Evans & Sons, by Protheroe & Morris, at 11.

FRIDAY

Trade Sale of Ferns, &c., at The Nursery, Enfield Highway, by order of Messrs. C. Lucas & Co., Ltd., by Protheroe & Morris, at 11.30.

A Collection of Established Orchids, the property of a Nobleman, at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 12.45.

Application of Electric Energy to Plant Growth.

Many years ago the late Sir William Siemens showed Strawberries forced by the electric light, at a meeting of the Royal Society. The fruits were of good flavour and had ripened in much less than the usual time. He also gave details concerning the application of the electric light to the growth of wheat and other plants. Our curiosity being roused by these results we took an opportunity of visiting Sir William Siemens' garden at Tunbridge Wells, at his request, and were not a little astonished at the results achieved. They were indeed so remarkable that the account of them might well seem incredible to those who had not the opportunity of seeing the results. (See *Gardeners' Chronicle*, April 3, 1880, p. 432, fig. 75.) Of course the question of the actual cost and of the net profit to be derived from the process was not at that time considered. We saw enough, however, to convince us that there was nothing to prevent the electric light being used in the winter months with profit, when solar light is deficient. Experience alone seemed required to convert the experimental into the commercial stage. Since that time various experiments have been made in France and in the United States tending to show that, with careful attention to details, much time may be saved, much labour spared, and good, that is to say profitable, results obtained. We had hoped that some of our societies and institutions would have taken up this matter which is obviously one of much practical importance, but our usual dilatoriness has up to the present prevented much being done, and we prefer to put money into the pockets of the foreigner rather than take the necessary trouble, and incur the inevitable risk attendant upon new enterprises. We believe, indeed, that some experimental cultures are now taking place at Bitton, Evesham and elsewhere, but these are of a different nature and have no relation to the use of the electric light for forcing purposes. Now that electric instalments form a part of so many country houses, it is indeed wonderful that so little progress has been made since the marvellous results of Sir William Siemens' experiments were made known. Now, however, we learn that Mr. B. H. Thwaite, a civil engineer, of 29, Great George Street, Westminster, has patented a means of applying the electric light and energy, the details of which appear to us to be so hopeful that we give the following specification in his own words:—

"This invention relates to an artificial method of stimulating the growth of vegetable, fruit, flowering, and other plant-life.

"It is well known that the rays projected from the voltaic arc electric light have markedly stimulating effects upon organic vegetable growth, and that the vigour of such growth is also stimulated and assisted by the passage of electrical energy through the moist earth supporting the roots; and it is also well known that carbon di-oxide is absorbed by the leaves of plants, and that a certain temperature environment is also necessary for the sustenance of certain kinds of flowers, vegetables, and fruit. The value of the nitrogenous element of sulphate of ammonia as a fertiliser is also well known.

"My invention consists in harnessing the intentional and consequential products of a combined suction or pressure-producer gas engine, and electric energy generating plant for providing all the defined and beneficial influences on plant life, in an economic and effective manner.

"I utilise the jacket water of the gas engine for heating the conservatory or glasshouse. I also utilise the carbon di-oxide of the gas engine exhaust gases for feeding the leaves, first purifying such gases before allowing them to enter into the immediate environment of the plants.

"I utilise the electric energy produced by the gas engine power in the following manner:—

"Assuming that the glasshouse protecting the vegetable growth is arena or circus-like in which, in circular tiers, are placed the potted flowering, fruit, or other plants.

"On a pole or post in the centre of the arena and which may support the roof, I suspend a powerful arc lamp equipment having a reflector, so arranged that the projected luminous beam is made to very slowly revolve, and in such a way as to bring its luminous influence on every plant, in intermittent and controllable periods of time.

"I may provide the arc light with a coloured lens to permit the isolation of the blue rays in the luminous beam from the red, or *vice versa*.

"Instead of the arena-like form of glasshouse I may arrange two long greenhouses parallel to each other, but connected by semi circular connections at each end. In such a long continuous glasshouse I suspend the arc light from small electric locomotors travelling on a central rail fixed just below the ridge of the roof, and running entirely round the two greenhouses.

"In this application I provide two arc lamps placed side by side, one having its reflector projecting its beams on one side, and the other projecting its beams on the opposite side.

"Of course, I may employ several couples of these reflector-equipped arc lights which travel either continuously or intermittently around the glasshouse; by this means the electric light beam is brought into active service for every plant in the glasshouse, and for any period of time required.

"I connect the electric supply, of a suitable character of energy (electric static), to the earth surrounding and sustaining the roots of every plant. This supply will invariably stimulate by electrolysis the growth of the plants.

"I prefer to water the plants from a central source, which water I also mildly electrify, the distributing pipes being electric non-conductors, or, if of metal, the pipes must be insulated.

"If the glasshouse is of the arena type, the distributing water supply pipe radiates from the central post and supply, and is slowly rotated by means of an electric motor, the distributing pipes either being equipped with distributing sprays or they are perforated so that the water falls on all plants as the service pipe rotates.

"When the glasshouse is of the rectangular type the electrified water distributing pipes slowly travel by means of an electrically driven gear, the water issues in sprays from the pipe and falls on to each line of pots.

"The application of my invention will have the effect of forcing the growth of fruit and flowering plants and vegetables, and will be especially appreciated in parts of the country near the large cities where the hours of sunlight are few and uncertain, and where the atmospheric temperature and hygrometric conditions are exceptionally variable.

"It is remarkable that the most economic method of converting the heat of coal fuel into work is also the most perfectly applicable to the electrical, thermal, and chemical stimulation of organic vegetable life. My invention harnesses all the qualities of this system of power-production to most satisfactorily effect the object in view, for instance, in the application of my invention on a large scale in which I use ordinary bituminous steam coal instead of anthracite for power gas generating purposes, I recover the ammonia from the gas produced, in a concentrated solution, for fertilising the soil in the rearing pots, &c., or I may convert it into a solid form as ammonia sulphate.

"My invention secures for the object defined, the efficient recovery of

"1. The nitrogenous matter of the coal.

"2. The sensible heat of the gas engine jacket water.

"3. The carbon di-oxide of the perfect products of combustion of the power gas, and

"4. Their sensible heat, all being available and efficiently utilised in addition to the electrically transformed power, to effect the object in view."

ROYAL HORTICULTURAL SOCIETY.—The next meeting of the Committees will be held on Tuesday, September 11, in the Society's Hall, Vincent Square, Westminster, 1-6 p.m. A lecture on the "Education of the Cottage Gardener" will be given by Mr. T. S. DYMOND at 3 o'clock.

HOW TO CULTIVATE GLADIOLUS PROFITABLY.—In order to obtain a profitable price for the flowers growers are advised to so arrange the planting or potting of the corms as to have the plants in bloom in the spring months and in October and November, seasons at which buyers are readily found for them, whilst enquiry is very infrequent during the summer. For flowering in the spring months the American corms are to be preferred, and the first potting made at the beginning of January. For late flowering the corms must be kept cool and dry till the middle or end of the month of June, and then planted in batches as may be required. *Die Bindekunst.*

BRITISH GARDENERS' ASSOCIATION. The special meeting to take place on September 12 at the Bible Society's Rooms, 5, St. Andrew Square, Edinburgh, will be held at 5 o'clock instead of 7 o'clock, as announced.

ROYAL GARDENERS' ORPHAN FUND. At the recent show of the Earley and District Cottagers Society one of the tents was set apart for the sale of fruit and flowers in aid of the above Fund, and Mr. T. NEVE, the local honorary secretary, was thus enabled to forward to London the sum of £5 0s. 3d.

PRESENTATION.—The employés of the Warren House Estate and Gardens presented Mr. C. J. ELLIS, on the occasion of his recent marriage, with a handsome marble clock.

THE FRUITERERS COMPANY OF LONDON. In consequence of Mr. GEORGE BUNYARD, V.M.H., being master of this company this year, he invited the Court to visit the firm's nurseries, at Maidstone on the 28th ult. The day being very hot the home nurseries where the glass houses and the herbaceous plants, vines, &c., are cultivated were passed, and the visitors spent all their time in the Allington Fruit Tree Nurseries, where they were deeply interested in the abundant crops of Apples upon the orchard trees and the plot of 400 kinds of Bush Apples on the Paradise stock. There was ocular demonstration of the systems of culture and pruning to be followed if home growers are to hold their own against foreign competitors. The various operations of propagation and training were duly explained, and, on leaving, the party heartily congratulated the manager [illegible] upon the extent of the nurseries, good culture of the trees, and absence of weeds.

BOOK-KEEPING DOWN TO DATE. By ANDREW M[illegible]. London: EFFINGHAM WILSON, 51, Threadneedle Street; Glasgow: W. & R. HOLMES, 3, Dunlop Street.] This is a third [illegible] of a useful book, and claims to be [illegible] date." The writer knows his subject [illegible] aims at providing a convenient [illegible] volume suitable for students and [illegible] refresh the memory of workers. [illegible] for examinations in book-keeping [illegible] consult it as the information [illegible] quite comprehensible, even to a novice.

FIG. 74.—DWARF PHLOX "TAPIS BLANC," A VARIETY GROWING FROM 6 TO 12 INCHES HIGH; FLOWERS, WHITE. FROM SPECIMENS SHOWN BY MESSRS. GUNN AND SONS AT THE R.H.S. MEETING ON AUGUST 28. (See note in last issue, page 1[illegible])

THE PREVENTION OF COMMERCIAL CORRUPTION.—The *Florists' Exchange* in reprinting from our pages some remarks on this subject adds that "There will always be, we fear, different and differing views held on the very objectionable practice of giving and receiving commissions, and the evil has become so common and is so deeply engrained in mankind generally that it will be difficult to eradicate it, even though the effort be backed by law. Not long ago, after the appearance of some comments on the subject of "Gardeners' Graft" in our columns, we received a communication setting forth that the man who knew where to purchase goods profitably to his employer was entitled to any commission that the seller might see fit to give the gardener. The writer of that letter evidently did not consider that the wages he was receiving from his employer were paid to him to do the very best he could for those he was serving, both in the buying of goods and in every other way. A Philadelphia firm recently announced publicly by advertisement that it paid a certain commission to all gardeners buying of that particular concern. That seems to us to be one way of minimizing "graft"; for employers are thereby made aware that gardeners purchasing goods in that seed store would receive a "rake-off"; and, no doubt, would see to it that the same was credited to the actual buyer, and not his agent. As our London contemporary says: "There will be a difficulty in awakening the consciences of the recipients of commissions whether given by local or foreign tradesmen, for there are some men, too many, alas, with whom the eighth commandment is a dead letter; men who are willing to sink their manhood to the lowest level provided they can work for their own pockets all the time. For such men law has no terrors, and DANTE's Inferno is but a chimera. So what's the use?"

THE LASTING PROPERTY OF CLEMATIS FLOWERS.—The blossoms of Clematis Jackmanii, when removed from the plant as soon as they expand, will remain fresh for a week even in such a temperature as we have been enjoying (!) in this country lately. The flowers of this variety and others should find more employment in bouquets, and the various designs of the florist and floral decorator than is the case at the present time. *Die Bindekunst.*

KEW NOTES.

CEDRONELLA CANA.

A BED planted with this Mexican labiate commenced to flower in June and is now at its best. It makes a freely-branching, compact bush about 2 feet high, and has a strong but not disagreeable odour when handled. The whole of the inflorescence is of a rich rosy-purple colour, so that when the flowers drop it is still attractive. The species is not, however, hardy, but requires to be lifted and kept in a frame during the winter, or fresh plants should be raised from seeds sown either in autumn or spring.

MALVASTRUM LATERITIUM.

FOR covering a large space quickly this plant is most suitable, for while not growing more than 10 inches high, the creeping stems with their dark green leaves soon make a good sized carpet, studded with pale brick-red flowers produced on long stalks. A native of South America it is a hardy perennial, and it is growing and flowering freely in the present hot weather.

CENTAUREA BABYLONICA.

ONE of the handsomest plants belonging to this genus, C. babylonica, a hardy perennial, is an attractive object when well grown. It has bold foliage and stems reaching a height of 6 to 8 feet, covered nearly the whole length with yellow flowers. The stems and leaves are clothed with a white cottony down, giving the plant a silvery appearance. The species was introduced into this country nearly a century ago, but is seldom seen except in Botanic Gardens. The plants will grow in any good garden soil. The species is found in Asia Minor and Syria.

GENTIANA ORNATA.

THIS plant was first distributed by Herr Max Leichtlin in 1905 as Gentiana sp. It is now flowering, and has proved to be the true G. ornata, being quite distinct from the plant wrongly called by this name and figured in the *Botanical Magazine*, t. 6514. A native of the Eastern Himalayas and Sikkim, it occurs at elevations between 11,000 and 15,000 feet and is somewhat variable in habit. The present plant is of tufted habit, with many stems 5 to 6 inches long, narrow fleshy leaves, and solitary terminal flowers. These are about the size of those of G. septemfida and of a charming turquoise blue, the outside of the flower tube being conspicuously marked with dull purple and buff coloured stripes. It is evidently a free flowering plant and easy to grow, succeeding well in a moist and shady position.

PLANTAGO MAXIMA

is an ornamental Plantain from Siberia with large leaves, after the style of our native P. major. Its most distinctive feature is the long cylindrical head of flowers borne on a tall stem. The long stamens have a feathery appearance, and as the white flowers are produced freely the plant is very attractive. Plants raised from seeds sown in the spring flower the same year, and as a quantity of seed is produced on each plant it should soon become plentiful.

APLOPAPPUS CROCEUS

is a charming little Composite from the Rocky Mountains of Colorado, and grows about 1 foot high. It is of neat, compact habit, with small leaves and numerous yellow flowers about 1 inch in diameter. The most suitable place for this plant is in the rock garden, although it has also flowered well in the open border.

MISCELLANEOUS SPECIES.

THERE are many other interesting plants now in flower including Cacalia tuberosa from North America, with its large Plantain-like leaves, and stems 3 to 4 feet high, bearing singular looking flowers which are those of ordinary Composites. Jaborosa integrifolia is an interesting creeping plant from Buenos Ayres, forming a mass of dark-green foliage, amongst which are produced the Nicotiana-like flowers. One of the handsomest Pentstemons in flower at the present time is P. cordifolius, which is a shrubby, but only half hardy, species from California. The scarlet flowers are produced in great profusion on long, somewhat straggling, branches. It is usually killed in the winter even against a wall, except in the southern counties, but propagation by cuttings is readily effected, and plants may be kept through the winter in a cold frame. Carlina acaulis, with its curious thistle-like appearance and large flower heads, is also conspicuous in a bed by itself. Two late-flowering Dianthus are D. Noëanus from Rumelia, with narrow, grass-like foliage and white flowers with laciniated petals, and D. pinifolius from Greece, with light purple flowers in heads of three or four. Geum speciosum is a rare plant now in flower. It is a Caucasian species, found in 1891 by M. Alboff, who also was the means of introducing Campanula mirabilis. It has leaves similar to those of G. montanum, with orange-yellow coloured flowers produced on stems which grow about 1 foot high. *W. I., Sept. 2.*

FIG. 75.—VIEW IN ST. PAUL'S CHURCHYARD.

UNDER THE SHADOW OF "ST. PAUL'S."

ONE of the oases in the great City of London are the outer precincts of St. Paul's Cathedral, for they are laid out as lawns and flower beds, with fountains wherein the City birds splash and lave. Around the base of the fountains and along the numerous paths, with which the whole is intersected, are seats for the tired City worker or the visitor. The vegetation could hardly be described as vigorous, for apart from the sulphurous laden atmosphere the plants do not enjoy much light or air, the great dome casting its shadow around all, and the neighbouring houses approaching near to its walls. However, the most is made of the opportunities, and it is pleasant to look upon the grass and to enjoy the seclusion and quiet which the spot affords. One of the open spaces near to the Watling Street entrance has been laid out as a flower bed (fig. 75) against a background of shrubs. This piece of bedding has for its design the City of London's Arms and Motto worked out in carpet bedding. The quarterings of the shield are composed of Mesembryanthemum cordifolium variegatum, the cross and dagger being formed with Alternanthera. The whole of the shield is outlined with a broad band of the common Thrift. In front is a circular band in which is worked the motto, *Domine dirige nos*, the letter

being composed of golden coloured Pyrethrum on a ground-work of Saxifraga. Beyond is a row of Thrift, and the whole is completed by a line of Echeveria secunda glauca. Other flowers in the bed, apart from those used in the armorial design, are Pelargoniums, Koeniga (Alyssum) maritima, Celosias, Marguerites, Antirrhinums, Liliums, and a solitary specimen of Humea elegans. The shrubs at the back comprise Hollies, Privet, Aucubas, Prunus Pissardi, which looks very uncomfortable, and right under the wall a straggling specimen of the Tree of Heaven, Ailanthus glandulosus.

SPIRÆA MILLEFOLIUM.

From Mr. T. Smith, of the Newry Nurseries, we have received a spray of this distinct species of Spiræa (see fig. 76). Were the leaves seen by themselves, they might almost be mistaken for those of the common Milfoil, their superficial appearance closely resembling that plant. They are about 3 inches long, bipinnate, and very much sub-divided along the pinnæ. On their upper surface they are greyish-green and glabrous, but beneath they are covered with a dark-coloured tomentum. The whole of the shoot is of a sticky character, and even the brown-coloured stem is viscid. The flowers are produced in a terminal compound raceme, the example sent having an inflorescence about 6 inches in length. The individual flowers are of small size and not unlike those of the wild Fragaria vesca, the white petals being set off by a centre of numerous yellow stamens. The plant is by no means common in gardens, although it was introduced into this country from California in 1880. It forms a bush from 2 to 6 feet in height, and is hardy in favoured parts of this country. The plant has numerous synonyms.

Mr. Smith also sends us sprays in flower of Polygonum Sachaliense, one of the handsomest Knotweeds in cultivation, forming, as it does, clumps 6 to 8 feet high of graceful wand-like stems, with their accompanying bold truncate leaves.

FORCING FRUIT TREES IN POTS.

(Continued from page 158.)

Cultivation.

Fruit trees growing in pots require to be repotted every year. I have frequently been asked how often we pot our trees, and when the answer is given "every autumn," some surprise is expressed. It is, however, necessary to do this. I would not say that the trees would not succeed the second year, but after that, the soil becoming exhausted, growth would be weaker, the trees being then dependent mainly upon extra feeding. We like to commence potting the earlier forced trees by the middle of September, time is thus allowed for the roots to make fresh growth before winter. The "ball" of each tree is carefully reduced with a small two-tined claw, a process that is readily accomplished after a little practice. Sufficient of the old soil is taken away to permit of the tree being put back into a pot of the same size, as a rule, and sufficient space left that fresh soil can be worked down all round the roots, and made firm with potting sticks. A good layer of fresh soil is also placed over the rocks, and a moderate amount over the surface of the roots. In instances of trees that have a tendency to thrive above the average degree a larger size of pot is employed, and if others give indications of weakness at the root they are put into smaller pots. Our smallest trees are in 10-inch pots, and others are in larger sizes up to about 15 inches diameter for the largest. It must be an exceptional case to have larger pots than the largest in use here. To pot firmly is most essential, and at the same time carefully, so that no vacant space is left next the pot. To say that pots must be clean is almost superfluous; but the drainage, which in amount should be quite up to the average, should be composed of clean materials also. We prefer to place all the trees under glass as soon as they are repotted. Then, if given one good soaking of water, they will stand for some time. When the weather is warm and dry they are syringed at least once each day, otherwise, with some few leaves still upon them, there may be a tendency to shrivel. I try to keep these leaves fresh for a time, and success in doing so indicates that all is well with the trees. In housing these newly-potted trees, they are stood pot to pot, or nearly so; thus we can accommodate the trees of four houses in one house with ease, thereby saving room for the late trees and for such catch crops as Chrysanthemums, &c.

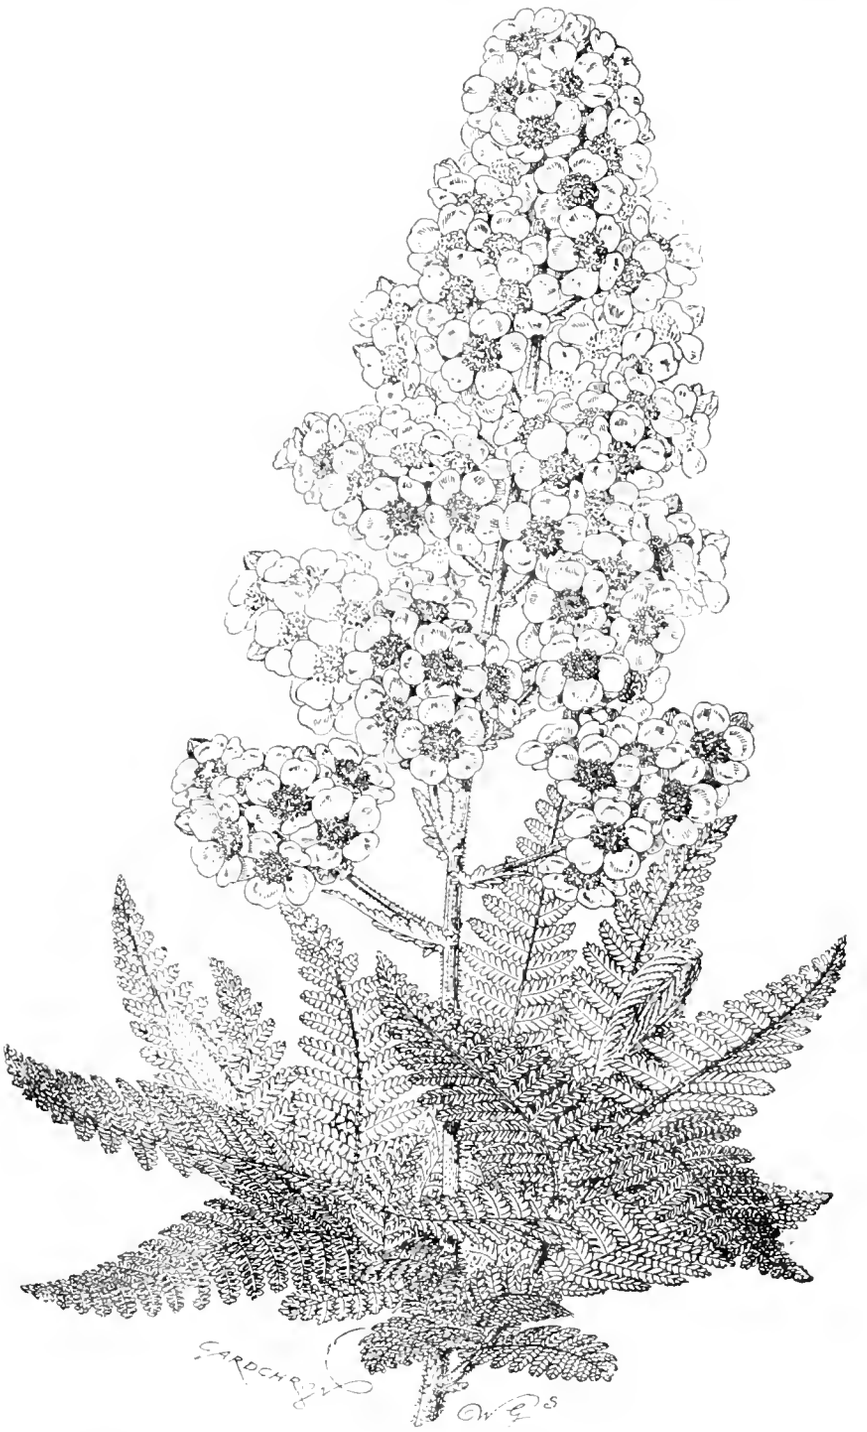

Fig. 76.—Spiræa millefolium: flowers white, with a cluster of yellow stamens.

Nature of Soil.

This should be of as good a quality as it is possible to obtain. We have, up to the present, always used some of the Banstead loam—say about two-fifths. (I said up to the present, that is, up to last autumn, but I have now ceased to use this loam for anything, as the quality has so much deteriorated. It is not now worth, in my opinion, one-third of its cost.) I now obtain all the special loam for fruit trees and other plants from Kettering, in Northamptonshire. This is worth three times as much as the Banstead loam, and there is no waste with it. I can get this Kettering loam delivered to our nearest goods station for 5s. per ton less than I paid for that from Banstead. The new loam needs tempering with one of lighter character, and for this purpose we use a good local loam with some iron in it; of this loam about another two-fifths is added. The remaining fifth is made up of old mortar rubble after it has been pulverised down to the size of small nuts, or less, also of some well decomposed manure, such as that procurable from a spent hotbed. This mixture, after being turned a few times,

should be kept dry for the better handling when used for potting. We let it lay for a few weeks in the heap before it is used. Loam of a calcareous character, that is, one having a proportion of lime in it, is most essential, from whatever source it may be obtained.

TOP-DRESSING.

We make it a practice to top-dress the trees during the time of growth; this is done during the stoning period, so that the roots may derive benefit from this addition when the fruits commence to swell quickly. For this top-dressing we use a mixture of good loam (Kettering, this spring) with some decomposed manure, and, in addition, a manure that is now advertised in the gardening papers, and known as "Hop Manure" (Wakeley's). This manure is chiefly composed of spent Hops, and it suits almost any kind of fruit tree in pots; Fig trees, in particular, root into the top-dressing thus made with great rapidity. I have not had this Hop manure analysed, but I believe it contains a good proportion of both phosphates and potash as constituents. The top-dressing is applied firmly around the sides of the pot well up above the rims, and in such a way as to provide for the watering process nearer to the stems. Later in the season, say when the fruits are all gathered, the top-dressing will be found to be percolated with roots throughout, hence it is the means of providing such plant food as tends to build up the trees for another season.

THE AFFORDING OF WATER.

Some fears may be entertained that fruit trees in pots are much trouble in this direction; such, however, is not the case. If I might draw a comparison, I should say that Chrysanthemums want quite as much attention. After re-potting, extra care is necessary in order to guard against the old balls becoming too dry and the new soil too moist. When writing of re-potting, I should have stated that whenever a tree is found to be dry at the root it is placed in a tub and soaked before it is turned out of the pot. When forcing is commenced, the atmosphere of the house is kept in a humid condition by both syringing and damping down, and thus we prevent frequent watering at the roots. As growth commences, first with the opening of the flowers and the young leaf growth that so soon follows, it is necessary to make sure that the trees do not suffer from either extreme. With a little practice in the watering, it will soon become an easy matter. Later on, when in full growth, an abundant supply is needed, for drought then would be most injurious.

MANURIAL STIMULANTS.

When the fruits are swelling freely, say when as large as the common nut, an occasional application of manure is beneficial. At first, I recommend the use of an artificial compound in which both phosphates and potash are important factors; such, for instance, as a compound containing from 25 to 30 per cent. of soluble phosphates, 18 to 20 per cent. insoluble phosphates, and 2 to 3 per cent. of potash. The phosphates are most important in the cultivation of stone fruits for the proper development of the "stone" and kernel, without which it is impossible to secure good fruits. This same manure may contain 4 to 5 per cent of ammonia, which will excite root action. The better method of application is to take a pinch between the thumb and finger for a smaller size, and between the thumb and two fingers for a larger size pot. Such an application if given once a week will be productive of good results when average crops are swelling, rather more being applied for heavy crops. As the fruits begin to swell freely after stoning, liquid manure will then serve a good purpose, but an application once a week will be ample, this taking the place of the artificial manure. Cease giving any manure when colouring has well set in; depend then rather upon close attention to the ordinary watering.

AMOUNT OF CROP.

When a good set of fruit has been secured guard against any temptation to crop the trees too heavily, but do not thin rashly. I am now thinking more particularly of Nectarines, Peaches, and Plums. It does not do to thin Cherries too freely; one must watch these very closely and be quite sure that the fruits will swell, then thinning can be done with a pair of vine scissors. In any case, bear in mind that a heavy crop means smaller fruit, with the same development of stone, but with a lesser degree of fleshy matter around it. It is a difficult matter to say how many Cherries a tree should bear; one must judge for one's self, taking into consideration the health of the tree and its leaf development. Our smaller trees of both Nectarines and Peaches will carry from 6 to 8 fruits, the medium-sized trees up to 12 and 15 fruits, and the largest up to 20 and 24 fruits. Plums will carry about one-third more in numbers. *J. Hudson, Gunnersbury House Gardens.*

(To be continued.)

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

OUTDOOR PEACH CULTURE. — Writers on this subject seem to infer that Peach leaf blister is of somewhat recent trouble. I well remember how injurious a pest it was as long since as 1850 even in so comparatively warm a locality as that of Southampton; nevertheless, very fine Peaches were produced there. One of our best open wall Peach growers was the late Mr. Lindsay, of Ditton Park Gardens, Slough. His Peach wall 30 years ago was one of the best in the kingdom, and in spite of blister, and an entire absence of canvas or other protection, his crops of fruit were almost marvellous. But in the old days gardeners had no greater object for pride in their gardens than in showing fine clean Peach walls. Is there less capacity to cultivate such trees now? I think not. The difficulty lies now, I fear, in our very prolonged, cold, ungenial springs, for without cold the blister fungus seems comparatively harmless. Peach trees are hardy, certainly, but the young leafage is comparatively tender and seems to need shelter from cold in the spring quite as much as the bloom does. *D.*

— On p. 167 *M. M. N.* mentions as a reason why the Peach is not more generally grown out of doors that the fruits have but poor flavour. My experience is just the reverse, and I have heard many ladies and gentlemen remark "Give me a good Peach from outside, they are very much nicer!" *W. A. Cook.*

— Mr. Ward appears to treat "blister" very lightly. Although Devon may be a favoured county, some of its gardens are not in ideal spots, and many suffer from the effects of cold, and in an ungenial spring "blister" is very serious. I am aware that removing the blistered leaves is the only remedy, but when the disease is severe, entailing the removal of a large proportion of the foliage, all the trees do not recover readily; that is my experience in *North Devon*

BEECH TREES AND LIGHTNING.—I should be glad if any reader of the *Gardeners' Chronicle* can corroborate this incident. Seventeen or 18 years ago, when I was but a lad living at home in Hampshire, we had a very heavy thunderstorm, accompanied by vivid, forked lightning, and a Beech tree was struck by lightning on the Rotherfield Park Estate, at East Tisted, near Alton, Hants. The tree stood in the hollow opposite the end of Winchester Wood nearest the mansion. I have always remembered it as a Beech tree and am almost sure I am correct, but as it happened so long since and I was only a lad at the time, I cannot be sure. No doubt there are still some living on the estate that were there at the time I mention, and they could tell us if I am right or wrong. *W. A. H., Dulwich Common.*

— I believe it to be a rare occurrence, but I saw one Beech tree, say about eight years ago, which had been struck by lightning. It was in West Berks, and the tree stood in the middle of a wood which was comprised mostly of Beeches, the majority of which were from 50 to 70 feet in height and 1 feet to 5 feet in circumference. This one was broken off by the lightning probably at about from 20 to 25 feet from the ground, and the stump which was left standing was splintered so much that it resembled a large bundle of plaster laths wrapped round with a piece of bark. All the way down one side a strip of the bark was taken out by the lightning, otherwise the tree was sound. *F. M.*

— The Beech tree is not altogether immune from the attacks of lightning, inasmuch as about 15 years ago, to the best of my recollection, when upon a casual visit to see Wyddrington House, Edgbaston, the interesting seat of J. E. Wilson, Esq., the head gardener, Mr. Wm. Jinks, pointed out to us growing in close proximity to the conservatory adjoining the house a tall old Beech tree near the carriage drive, and which had been struck by lightning a few weeks previously. As the whole of the foliage had become shrivelled the tree was condemned to be cut down as past recovery, though strangely there was no other evidence of injury to either bole, branch, or the bark; apparently the comparative smoothness of the bark of the tall and upright bole acted as a more facile conductor of the electric fluid than that of a large-branched and rugged-barked one. Mr. Jinks drew particular attention to this circumstance in evidence of the fact that the Beech was not altogether immune from lightning. Mr. Jinks was only a few yards distant from the tree when it was struck, and distinctly saw the electric fluid pass down the tree in question and appear to enter the ground without leaving any symptoms of disruption. Fortunately, though considerably shocked, he himself was not injured. It may be added that the tree constituted one of the boundary trees of several other kinds forming a large clump. It is interesting to observe the curious behaviour of lightning when in contact with trees, and I have witnessed a few curious instances during a long life, one of the most remarkable being that which occurred some 12 months ago within a quarter of a mile from my abode. One sultry forenoon, when passing along one of the main public roads here, the sky suddenly became cloudy, and a thunderstorm burst overhead; almost simultaneously a very tall and straight-boled Larch was struck by the electric fluid—as witnessed by myself and a friend who had taken shelter beneath a large Elm, only about 15 yards distant. The stricken tree was the only one of its kind in the long belt growing in close proximity to the roadside, and being somewhat taller than the others, with its pointed apex, no doubt it afforded a ready conductor to the fluid. Subsequent investigation proved that the tree did not exhibit any trace of injury excepting the scattering of a few small pieces of the exterior bark from the upper portion of the trunk, and at the present time the tree appears to be as flourishing as ever. The rain was of short duration and consisted of a few large drops only. The most remarkable feature, however, was the apparent course of transit of the fluid when leaving the Larch, it having passed to an adjacent tree—a variety of the English Elm growing about 6 feet distant, the only visible rupture being a slight abrasion of the bark close to the ground, immediately above one of the roots, about the size of a stout walking-stick, and which grew close beneath the surface of the soil—towards the low roadside embankment, and where its naturally bared root was found to be shorn of a portion of its bark. It should be noticed that the light, sandy soil round about was at the time in a very dry condition. *William Gardiner, Harbone, Birmingham.*

VEGETABLES AT SHREWSBURY.—(see p. 166). *A. D.* has certainly made a suggestion that most exhibitors in the vegetable classes at the late Shrewsbury show will heartily agree with. I refer to the proposal to form a champion class in which the exhibitors could meet each other without it being required that the produce has been raised from Messrs. So and So's seeds. There is the open class for 12 kinds, but the prizes in that class are quite unworthy the name of a rich society like Shrewsbury, and not comparable with those in the trade classes, hence the lack of keen competition. At the present time there are so many trade classes of equal value, or nearly so, that unless one were to buy seeds from each firm, in order to compete in each class, there could be no champion. The suggestion that all this year's prize-winners should compete in the champion class by compulsion, is, I think, hardly necessary, as anyone with the least pretension to become champion would need no inducement to urge him to compete. I feel quite certain that if the Shrewsbury authorities will consent to the suggestion that *A. D.* has put forward, there will be no lack of enthusiasm amongst the exhibitors. The conditions of such a

class should be made equal to all exhibitors, by stating beforehand the numbers of specimens permitted to each dish, and the maximum number of points to be given to each dish, after the system adopted in the fruit classes at Shrewsbury and in the vegetable class at Edinburgh last year. The suggestion will, doubtless, have the consideration of the Shrewsbury authorities, who are always anxious to do what they can for exhibitors and the public. Exhibitors have always been grateful to the trade for the encouragement they give to exhibitors of their specialities, and this appreciation will be none the less after the introduction of a champion class where the best of everything will have to be shown. *James Gibson.*

FRUIT IN KENT.—Apples are a fair crop, also Gooseberries, Raspberries and Currants; Pears in the open suffered severely from frost during April and May. Plums are quite a failure; Strawberries were a good crop. The soil here is from medium to heavy, resting on a gravel subsoil. *J. Roberts, The Gardens, Broomhill, Tunbridge Wells.*

LUTON HOO.—On paying a short visit to this beautiful place I was pleased to see the improvement that had been made during the last two years under the superintendence of Mr. A. Metcalfe. Extensive ranges of glass have been erected to grow fruit, plants and cut flowers. The Peaches and Nectarines appear wonderfully healthy, and have borne good fruits considering they have only been planted for two years. The kitchen garden looked as if no rain was wanted. Mr. Metcalfe has had water pipes put on the top of the wall all round the kitchen garden, thus the water is chilled before it is used, and can be applied to any part. Many cordon fruit trees have been planted. Some thousands of plants of Royal Sovereign Strawberry in 6-inch pots were plumping up well for early forcing. In the pleasure grounds the flower beds were very gay. There are some fine Conifers there that are well worth seeing. Mr. Metcalfe informed me that a Japanese garden, an Italian garden, and a huge rockery are features it is intended to add to the establishment. *Visitor.*

CARVING INITIALS AND NAMES ON TREES.—I am not surprised at Lord Durham prosecuting a man for carving his own and his wife's initials on the trunk of a tree at Lambton Park. Such vandalism is, unfortunately, far too often perpetrated, and the sooner a stop is put to the nuisance the better. The famous Beech trees at Knole Park, near Sevenoaks, which I visited some years ago with Lord Sackville, have been barbarously treated at the hands of the initial carver, while at the instigation of the late Earl of Derby I had the historic Wilberforce and Pitt Oaks fenced around to prevent similar injury. When I visited visited the picturesque Coney Island property of Lord Charlemont recently I was shocked at the mutilated stem of the Beech tree with the never-failing well of water in its trunk, which is pointed out to privileged visitors to the beautiful and interesting island. But I could give numberless instances of this form of tree mutilation, which is by no means confined to Britishers as the addresses plainly show. *A. D. Webster, Regent's Park, August 30, 1906.*

"A CORNISH TRIP."—In Mr. Druery's interesting article on his tour in Cornwall, he alludes to the fine Cordyline australis in Mr. Howard Fox's garden at Rosehill, Falmouth, as probably the finest specimen in the country. It is, indeed, a splendid example, but its dimensions are a trifle exceeded by a specimen at Enys, which was raised from seed sent from the Antipodes 46 years ago. When I last measured Mr. Howard Fox's Cordyline it had a girth of 5 feet 5 inches at 1 foot from the ground, whereas at the same height the Enys specimen had a girth of 6 feet 1 inch. This example divides a short distance above the ground level into four main trunks, which are again subdivided into some 36 heads, 10 of which bore flower in 1904. Mr. Druery speaks of the tropical appearance produced by Calla (Richardia) æthiopica [Africana], but this is seen nowhere to such advantage in the south-west as at Trelissick, where, in the first week in June, some thousands are in flower around the lake (see illustration in *Gardeners' Chronicle*, May 27, 1905). I may say that I was informed during a visit to Cornwall last spring that the Fern so largely grown in that country as Lomaria magellanica, and alluded to by Mr. Druery, was stated by the Kew authorities to be L. procera. Sir A. P. Vivian's seat is Bosahan not Basahan. *S. W. Fitzherbert.*

SOCIETIES.

ROYAL HORTICULTURAL.

Scientific Committee.

AUGUST 28.—*Present:* Dr. Maxwell Masters, F.R.S., in the Chair; Messrs. Rolfe, Arthur Sutton, Geo. Massee, Worsley, Saunders, Hooper.

Melon leaves.—Mr. MASSEE reported that the leaves submitted to him at the last meeting were sun-burnt and that there was no fungus present.

Diseased Deodar.—Mr. MASSEE reported that the trees were attacked by a species of Rosellinia. Leaflet No. 64 of the Board of Agriculture and Fisheries gives an illustrated account of the fungus and the method of combating it.

Japanese Iris.—Some specimens in a diseased condition sent from Romsey were referred to Mr. MASSEE.

Aerial roots on Vines.—The following communication was read from the Rev. Prof. HENSLOW:—

"Going over a florist's grounds and houses lately at Kenilworth, the florist called my attention to a peculiar coincidence. In a long row of vines, only one had aerial roots, and the Grapes on that plant only were much in advance in size (all were green) as compared with all the rest in the house. The root has a three-walled epidermis, the cells, of a thick cortex and pith, being three-walled, very compact, and full of water (no starch being present), with a feebly developed zone of phlœum and xylem. On allowing a root to lose some of its water by evaporation, I placed it in water for 12 hours, the cut-end being in air. It gained 30 per cent. of its weight in recovering its former condition. I shall be glad to hear if other vine-growers have noticed a similar coincidence, and, if so, whether they could trace any cause and effect. *G. Henslow.*"

Potatos.—Mr. ARTHUR SUTTON exhibited fruits of Solanum Commersoni with well marked heart-shaped, somewhat flattened, berries; berries of S. polyadenium, S. verrucosum, and of a reputed wild form of S. tuberosum were also shown. Two berries were exhibited from M. Labergerie's variety which were of a globose form, quite like those of an ordinary Potato. No fruits had, up to the present, been observed on plants of "Blue Giant," and up till 1904 M. Labergerie reported no fruits had been seen on his Potato. In the Journal of the *Société Nationale d'Agriculture de France* M. Labergerie reports this year that the fruits on his Potato are not round, but pointed or heart-shaped, like those of the wild type, and when they approach the round berries of our Potatos they still have a characteristic "*stilon*" or indentation. Mr. SUTTON also showed various drawings to scale, by Mr. Worthington Smith, of S. Commersoni and its assumed derivative. The form of the pollen-grains and of the hairs on the petals was particularly interesting. Dr. MASTERS showed tracings and drawings of most of the species and varieties inspected near Reading by certain members of the Committee recently, when the members present failed to perceive any material difference between M. Labergerie's variety and "Blue Giant," whilst both were widely different from S. Commersoni.

Aristolochia elegans, &c.—Mr. WORSLEY showed flowers of this species from the vicinity of Rhodes's tomb in Rhodesia, to which locality it must have been introduced from Brazil. The West African A. Goldieana [see fig. 72] was also noticed as spreading widely in Africa. Fruit pods of Ceropegia Woodi were also exhibited, presenting the usual cylindrical narrow form.

Leaves of Plums.—Mr. HOOPER called attention to the singular provision for the protection of the buds at the base of the petiole, and asked for other examples of a similar kind.

Various diseased leaves.—Mr. SAUNDERS exhibited leaves affected by a species of Psylla, Box leaves affected with Sphærulina buxi, and Violet leaves attacked by Cercospora violæ.

THE LATE PROF. MARSHALL WARD.—On the proposition of the Chairman, it was decided to send a letter of condolence to the widow of Prof. MARSHALL WARD, for many years a valued member of the committee. THE LATE C. B. CLARKE.—Reference was also made to the sad death of this distinguished botanist.

THE NEXT MEETING.—It was decided that no meeting should be held on September 11, but that the business should be adjourned till September 25.

READING HORTICULTURAL.

AUGUST 29.—The members of this society held their Jubilee Exhibition in Forbury Gardens, Reading, on the foregoing date. The number of entries exceeded those of last year, and a most successful show of flowers, fruit and vegetables resulted. Competition in many of the classes, notably those for fruit, was very keen. Four large tents were requisitioned to hold the exhibits. This being the 50th exhibition of the society, a luncheon, at which the Mayor of Reading (Mr. E. Jackson) presided, was held prior to the opening of the show.

PLANTS.

An important class was one for a group of miscellaneous plants arranged for effect. Five exhibits were staged, by far the best being that from E. WAGG, Esq., The Islet, Maidenhead (gr. Mr. D. Phillips), Codiæums (Crotons) were a feature of the group; 2nd, S. B. JOEL, Esq., Marden Erleigh (gr. Mr. F. Johnson). In an open class for four stove and greenhouse Ferns, E. WAGG, Esq., was again successful. The best four stove or greenhouse plants were shown by J. B. TAYLOR, Esq., Sherfield Manor (gr. Mr. T. Brown). Fuchsias are always shown well at this show. J. F. FRIEDLANDER, Esq., Whiterights Park (gr. Mr. F. Bright), was, as is usual, 1st in the open class for six specimens; indeed, this made the 21st time in 23 years that Mr. Bright has gained first position for these plants. Miss K. RATCLIFFE, Westfield, Reading (gr. Mr. H. Booker), was 1st for three specimen Ferns. J. FRIEDLANDER, Esq., was 1st among four exhibitors for six double-flowered Zonal Pelargoniums.

CUT FLOWERS.

Dahlias were a feature in this section. The cactus varieties were above the average quality, and of these there were no fewer than 7 exhibits in a class for 36 blooms in 12 varieties. Messrs. J. CRAY & SONS, Frome, were placed 1st with a grand exhibit, the varieties Mrs. E. Mawley, of a clear yellow shade, and J. H. Jackson, a dark variety, were conspicuous; 2nd, Mr. J. WALKER, Thame. The latter led for 24 show or fancy Dahlias, and for 12 varieties Messrs. J. CHEAL & SONS, Crawley, were placed 1st. This firm also secured the leading awards in the open classes for single and pompom Dahlias.

Roses were well represented. Mr. G. PRINCE, Oxford, won for 18 varieties, a flower of Ben Cant being very prominent in his exhibit. Messrs. F. TAYLOR, Chipping Norton, were 1st for 12 varieties. Keen competition was shown in the class for 6 Roses (nurserymen excluded), C. E. KEYSER, Esq., Aldermaston Court (gr. Mr. A. Galt), being 1st among nine competitors. The 1st prize in the class for 12 vases of any variety of cut flowers was taken by J. B. TAYLOR, Esq., his examples including Gloriosa virescens, Bougainvillea glabra, Carnation Raby Castle, Roses and Allamandas. The same exhibitor was also 1st for six vases of hardy flowers. Mr. W. PALMER, Andover Nurseries, was 1st for nine vases of Sweet Peas. Five exhibits were seen in the class for six vases of Asters; Mr. A. A. JONES, Caversham, won the 1st prize. The best decorated table was arranged by Miss G. PALMER, who used Sweet Peas of pink and blue shades, with Asparagus and Smilax. Miss JOHNSON had the best basket of sweet-scented flowers, and Mrs. H. W. DUNLOP the best decorated epergne.

FRUIT.

The fruit classes are usually well filled at Reading, and this year was no exception. In the class for six dishes of fruit there were six exhibits. G. W. FLEMING, Esq., Romsey (gr. Mr. W. Mitchell) was placed 1st, and he also won for three bunches of Black Hamburgh Grapes and for three bunches of any white variety of Grape. J. B. TAYLOR, Esq., was first for any other black Grape with the variety Madresfield Court. A dish of Barrington Peaches staged by S. MONCK, Esq., Coley Park (gr. Mr. Booker), secured the 1st award for these fruits. Lady SUTTON, Newbury (gr. Mr. J. Howard), showed the best Nectarines in a dish of the variety Pineapple. Plums were a very strong class. S. B. JOEL, Esq., gained the premier award with fine samples of Magnum Bonum, Jefferson's, and Kirke's. J. B. FORTESCUE, Esq., Maidenhead (gr. Mr. C. Page) was 1st for three dishes of dessert Apples. In the class for culinary varieties the Earl of CLANWILLIAM was 1st amongst 12 exhibitors. S. MONCK, Esq., had the best dessert Pears. Classes were also provided for Melons, Tomatos, and Cucumbers.

VEGETABLES.

Two competitors only contested the open class for Messrs. Sutton and Sons' prizes, and both were very excellent exhibits. Lord ALDENHAM, Elstree (gr. Mr. Ed. Beckett), was awarded the 1st place with 55½ points, and he was closely followed by G. D. FABER, Esq., Wallingford (gr. Mr. J. Dymock), with 55 points. For a collection of six varieties, F. D. LEYLAND, Esq., Basingstoke (gr. Mr G. Best), gained the 1st award.

Classes were provided for cottagers and artisans residing within 10 miles of Reading Market Place.

NON-COMPETITIVE EXHIBITS.

Honorary exhibits were numerous. Mr. GEORGE PRINCE, Oxford, staged a splendid group of cut Roses; Mr. F. EAMES exhibited bunches of hardy flowers in great variety. Mr. G. PHIPPEN showed floral designs; the UNIVERSITY COLLEGE, Reading, had an extensive and highly meritorious exhibit of Melons, Tomatos, Cucumbers and Grapes. Other exhibits were staged by Mr. T. RIGG, Caversham, Messrs. T. POWELL & SONS, Bath Road, Messrs. J. HOLDER & SONS, and Mr. S. J. VINDEN, Minster Street.

NATIONAL AMATEUR GARDENERS' ASSOCIATION.

LECTURE ON FERNS.

SEPTEMBER 4.—At the meeting of the above association held on this date at Winchester House, Old Broad Street, Mr. Chas. T. Druery, V. M. H., F.L.S., gave an interesting lecture, illustrated by lantern slides, on the wonders of Fern life, with special reference to the varietal Ferns of Great Britain. The first lantern slide represented an ideal landscape, or rather land and waterscape, of the Coal age, when the Ferns and their allies laid the foundation of our coal measures. The remarkable mode of reproduction common to all Ferns was shown on the screen by a number of unique slides reproducing the drawings of Count Suminski, who first completed the discoveries of the normal life cycle of Ferns in 1846. Mr. Druery then described numerous variations of this life cycle, practically demonstrating that every link in the normal chain of phenomena could be left out singly or in numbers and yet the final result of a new generation be reached. The wondrous fertility of Ferns through their spores was exemplified by a slide showing the total of one season's crop of spores from a single Fern plant in his own collection to be no fewer than 1,120,000,000, each of which is, moreover, potentially capable of producing several Ferns. Extraordinary sports, of which so large a number has been found wild in our British glens, lanes, hillsides, and even roadsides, together with the still more curious and beautiful forms which have been raised from these by selective culture, were next dealt with. A considerable number of fine photographic slides exhibited specimens of these in many species—tasselled, plumose, dissected and varied in innumerable ways, and often so different from the common plain, or normal type that unless acquainted with them one would not credit their origin. In connection with the few cultivated and improved varieties Mr Druery illustrated his own beautiful series of plumose Lady Ferns, the now well-known "superbum" section, by a number of photographed fronds, including one showing the pedigree and demonstrating how immense was the stride between parent and offspring in this particular case. This, however, was almost equalled by another slide showing the origin of some of the most beautiful plumose Shield Ferns. A picture of the lecturer's own British Fernery as it existed at Forest Gate was also shown.

ROYAL SCOTTISH ARBORICULTURAL.

THE members of the Aberdeen branch of this society made their second excursion for the season on Saturday, September 1st, their destination on this occasion being the Huntly district of the extensive estates of the Duke of Richmond and Gordon, in which is situated the famous Bein Hill Wood. There was a good attendance of members, including landowners, factors, and head foresters. The arrangements were ably carried out by Mr. Robert Scott, solicitor, Aberdeen, hon. secretary of the branch, while the party was conducted over the policies by Mr. John Duff, Factor, and Mr. John Rule, Head Forester on the estate.

The members met at Huntly Station, and were driven westwards in brakes by the banks of the Deveron towards Glass. A short halt was made at the Dunbennan Wood for the purpose of ascertaining how Larch trees planted in 1888 were withstanding the fungoid disease so prevalent in many parts of the country. There were evidences of the fungus Peziza Willkommii. On the whole, however, the plantation was found in a fairly healthy condition, with good promise of yielding excellent timber in the future. Interspered with the Larch in this wood are many young Scotch Pines, which showed vigorous growth. It was remarked in passing that the trees bore an exceptionally large number of cones, which were found to contain healthy seeds, but the cones being so numerous, they raised doubts as to the healthy character of the growth of the trees, it being a well-established rule that trees bearing a large number of cones are not so vigorous as those which have only a moderate number. But it was pointed out that cones were this year exceptionally numerous on those Pines. The party thereafter drove to the famous

BEIN HILL WOODS.

On entering the woods the great amount of space between the Larch trees caused comment, the opinion being freely expressed that underplanting could be resorted to with considerable advantage. The grass and vegetation was particularly rich in growth, affording evidence that plenty of light and air reached the undergrowth. The party next rambled through the extensive Bein Hill forest of Larch trees, led by Mr. Rule and Mr. Wilson. Mr. Rule stated that the Bein Hill had been planted from 65 to 67 years, being started in 1839, and completed in 1841. Originally there were 2,258 acres, and subsequently the area planted extended to 2,450 acres. The price of planting, including plants and cleaning, was £1,956. Other expenses were: Ditching, £225; grubbing whins, etc., £54; enclosing the land with stone rickle dyke, £464; road making, £180; expenses of survey, £76; bringing the total cost, including plants and planting, to something like £3,000, or to £1 6s. per acre. In the original planting 6,387,000 young trees were put in, and as the contract included the maintenance of the plants for four years, the contractors put in an additional 100,000 plants, as many of the plants originally planted had been placed in situations unsuited to them. In addition, also, the proprietor had subsequently, at an additional expense, to introduce another 650,000 plants, bringing the total number of plants to about 7,000,000. When the trees were from 20 to 25 years old, signs of disease were apparent, but now the trees are in a fairly healthy condition. While the average cost of planting 65 years ago was 17s. 6d. per acre, or including everything, 26s. per acre, the cost of planting now would amount to about £4 per acre.

The company proceeded to a point in Burnside Croft, where extensive clearing operations are in progress, and where Messrs. Lockhart, Huntly have erected an up-to-date saw mill. The members had the pleasure of seeing the mill in operation.

Mr. John Clark, forester to the Earl of Aberdeen, said that the planting of trees had largely influenced the climate in the neighbourhood.

The excursion was in every way most successful and enjoyable, although the weather was very hot.

NATIONAL DAHLIA.

(By Telephone.)

SEPT. 6 and 7.—The weather in all parts of the country, excepting Scotland, during the past fortnight has hardly been of a type suitable to the well-being of Dahlias. The soil has been much too dry, and the sunshine too hot and exhausting, for such cool and moisture-loving plants. But the gardener is more fortunate than the farmer in being able to somewhat mitigate such circumstances by artificial waterings and in instances where flowers are being cultivated for exhibition purposes, by the use of shades that preserve them from the colour deterioration they would suffer if exposed to the full rays of the sun. The annual show of the National Dahlia Society, however, that has just been opened at the Crystal Palace as these pages are sent to press is nearly, but not quite so full as that of last year, and the quality of the blooms quite as good as was expected.

The two nurserymen's classes for "show" Dahlias were for 48 blooms, distinct, and 24 blooms, distinct, the winner in the former class being Mr. S. MORTIMER, Rowledge Nurseries, Farnham, and he was followed by Mr. W. TRESEDER, Cardiff. The class for 24 blooms was won by Mr. GEORGE HUMPHRIES, Kington Langley, Chippenham.

In the classes for fancy varieties, the best exhibit of 18 blooms, distinct, was shown by Mr. J. WALKER Thame, Oxon, and he was followed by Mr. W. TRESEDER. Mr. GEORGE HUMPHRIES had the 1st prize for 12 blooms.

It is in the competitions for Cactus varieties that exhibitors show greatest interest, and visitors find effects most to be admired. The silver Challenge Cup, value £15 15s., was awarded with the 1st prize for the best collection of 18 varieties in bunches of six blooms each, and the fortunate winners were Messrs. J. STREDWICK & SONS, Silverhill Park Nurseries, St. Leonards, followed by Messrs. J. BURRELL & Co., Howe House Nurseries, Cambridge. Mr. JNO. WALKER won the 1st prize for 12 varieties in bunches of six blooms each, and the class for 48 blooms, distinct, was won by Messrs. STREDWICK & SONS, the 2nd prize being awarded to Messrs. KEYNES, WILLIAMS & Co., Salisbury.

The best collection of 12 Pompon Dahlias was shown by Mr. J. WALKER, and the best exhibit of 24 varieties of single Dahlias, which are always amongst the most beautiful, was from Mr. M. V. SEALE, Sevenoaks.

In the AMATEURS' section a silver challenge cup, value £5 5s., was awarded with the 1st prize for the best exhibit of 24 blooms of distinct varieties of "show" or "fancy" Dahlias or the types intermixed. This class was won by Mr. TOM JONES, Bryn-pen-y-lan, Ruabon, who likewise exhibited the best collection of 12 "show" blooms, distinct varieties.

Class 21 was an important one, in which a silver challenge cup value £10 10s. was awarded to the Rev. ARTHUR BRIDGE, Worth Rectory, Crawley, for the best collection of nine varieties of Cactus Dahlia in bunches of three blooms each.

The above were some of the more interesting competitions.

GARDENERS' DEBATING SOCIETIES.

BATH GARDENERS'.—A supplementary excursion to the recent successful outing of the above society was arranged for the under-gardeners and members who could not join in the previous one. The outing, which took place on Thursday, August 23, was to Longleat and Frome. The party was met at Longleat by Mr. Gandy, Head Gardener to the Marquis of Bath, and he conducted them through the garden and grounds. The party next journeyed to Frome, where they were met by other members who had travelled by special motor. Mr. Iggulden, of Frome, gave the party a hearty welcome and conducted them through his nursery. Two large vineries of Gros Colmar Grapes were much admired. *L. A.*

CRAWLEY AND DISTRICT GARDENERS'.—The third annual exhibition of this society was held at The Elms, Crawley, the weather being perfect. Mrs. Messel, Nymans, Handcross, opened the exhibition at 2 p.m., being introduced to the company by the president, Mr. Jos. Cheal. The quality of the exhibits generally was very good. Mr. H. Hemsley and Mr. R. H. Holton fulfilled the offices of honorary secretaries, and the thanks of all concerned are due to them and to the committee for the success attending the show. The chief awards made were:—Mr. E. Neal (gr. to John A. Nix, Esq., Tilgate), was awarded a Gold Medal for a group of plants and a collection of fruit, the same honour being granted Mr. A. B. Wadds (gr. to Sir Weetman D. Pearson, Bart., M.P., Paddockhurst, Worth), for a group of plants and 50 dishes of Apples, and to Mr. J. Martin (gr. to P. Saillard, Buchan Hill, Crawley), for a group of plants and collection of Fruit; Mr. J. Comber (gr. to L. Messel, Nymans, Handcross), won a Silver-Gilt Medal for a choice collection of fruit; and medals of the same value were also awarded Mr. W. Shepherd (gr. to H. Hobson Finch, Esq., Goff Hill, Crawley), for a group of plants and a collection of fruit; to Mr. C. Daisley (gr. to Rev. A. Bridge, Worth Rectory), for a collection of vegetables; to Mr. J. White (gr. to Mrs. J. Goddard, The Elms, Crawley), for a group of plants, and to Mr. H. Brookes (gr. to Miss Rawson, Deerswood, Ifield), for a group of plants and a collection of fruits. Silver Medals were awarded Mr. J. Guyatt (gr. to F. L. Charles, Esq., Timberham, Lowfield Heath), for a collection of vegetables; Mr. W. Dowsett (gr. to V. Silberberg, Esq., The Manor House, Crawley), for collections of fruits, flowers, and vegetables; Mr. H. Wilkins (gr. to Alfred Beyfus, Esq., Lovell Lodge, Lowfield Heath), for a group of Cactus Dahlias, &c.; Mr. E. Seymour (gr. to C. Fox, Esq., The Old Rectory, Ifield), for a group of Begonias; and to Mr. W. Wilks (gr. to Major Nelson George, Lovell House, Lowfield Heath), for a collection of plants and fruit. Medals were also awarded in the amateurs' and cottagers' sections for best kept gardens. Messrs. J. Cheal & Sons, Lowfield Heath, had a non-competitive exhibit of Cactus, single and Pompon Dahlias, and cut flowering trees and shrubs, which were greatly admired, they also had on view several plans and sketches showing the formation of new grounds and gardens. Mr. Robt. Neal, Bonnett's Nursery, put up a choice exhibit of hardy flowers and Roses. All surplus profits from the exhibition are to be divided between the Royal Gardeners' Orphan Fund, and the Crawley Cottage Hospital.

MARKETS.

COVENT GARDEN, September 5.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday, by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate, not only from day to day, but occasionally several times in one day.—ED.]

REMARKS.—Tomatos, both outside and indoor grown, are a very heavy supply with prices ruling low. Mushrooms have been scarce owing to the dry weather. Apples are very plentiful. English Plums are nearly over, and supplies from California are furnishing dessert varieties. Melons, both English and foreign, are very plentiful. Peaches are now a short supply. Supplies of Nectarines are nearly over. Consignments of vegetables are very short indeed, owing to the dry season. Trade generally is improving. *E. H. Rides, Covent Garden, Wednesday, September 5, 1906.*

POTATOS.

Large supplies of Potatos are still coming from all districts, and trade is very dull. Lincolns, 55s. to 65s.; Bedfords, 60s. to 65s.; Kents, 70s. to 80s., Blacklands, 55s. to 60s. *John Bath, 32 and 34, Wellington Street, Covent Garden*

COVENT GARDEN FLOWER MARKET

I have never before seen so many empty stands. Flowering plants are a short supply, that is of really first-class material. Asters of fairly good quality are seen, but there are many that would not satisfy the best florists. Chrysanthemums vary considerably, some are very good and make satisfactory prices. Two distinct types of these plants are forthcoming, those that have been disbudded and well finished, which always make good prices, and those from plants from the ground and potted, but these latter are of little value. In quoting prices, there may appear much difference, but while the best make from 18s. to 24s. per dozen, many inferior ones are sold at from 4s. to 6s. per dozen, or perhaps less. Good Zonal Pelargoniums can be had; the Ivy-leaved and show varieties are now practically over for the season. Good white Marguerites can be had, but there is none of the yellow kind. Liliums do not sell well; Zinnia elegans double variety is good. Supplies of Campanulas are now nearly finished. Bouvardias are not of very good quality. Spiræa japonica is seen in well-grown plants; there are also some well-flowered specimens of Rose Madame Levavasseur. Ferns, Palms and other foliage plants are well supplied, and may be bought at very low prices. Kochia scoparia comes from several growers. The other day I saw the two sorts growing together; the one received from a Continental firm as K. scoparia is not worth growing, but this firm also sells the desirable variety, under the name of K. trichophila. Hawkers have been doing a big trade with these plants in the suburbs.

CUT FLOWERS.

There is quite a glut of Asters, and though fresh blooms of good quality may make good prices, many are cleared at about 1s. per dozen bunches, or for perhaps even less. Chrysanthemums are over-plentiful. The same remark applies to cut Chrysanthemum flowers as with pot plants, and it is most difficult to give even approximate prices. Very fine blooms may be bought at 1s. 6d. to 2s. 6d. per dozen others are sold at about the same prices per dozen bunches. Liliums are good and plentiful and prices which vary from day to day are low. They were fetching just double the price last Saturday to what they realised on the same day of the previous week, but they were cheaper again this morning. Roses of good quality were offered at very low prices, and it is quite impossible to sell blooms of second quality. Supplies of Carnations are also over-done. The American varieties are very good. Dahlias are seen in large quantities, but Asters and Chrysanthemums being over-plentiful. Dahlias can scarcely pay for their cutting. Physalis Franchetti and Viburnum Opulus (the Guelder Rose) with red berries and red-tinted foliage are very pretty. The white and the purple Scotch Heather sell freely. Asparagus, Smilax and other foliage is over-plentiful and their prices are low. *A. H., Covent Garden, Wednesday, September 5, 1906.*

THE WEATHER.

THE WEATHER IN WEST HERTS.

Two record temperatures. On five consecutive days during the past week the temperature in the thermometer screen rose respectively to 83°, 92°, 91°, 92½°, and 87°. Both 92° and 92½° are higher than any shade temperatures that I have previously recorded here at any period of the year. The nights, on the other hand, were only a few degrees warmer than is usual at this season; consequently the range in temperature was very great. On one day the difference between the lowest and highest readings of the thermometer screen amounted to 40°, which is the greatest range in any one day of August of which I have here any record. On the 3rd inst. the ground at 2 feet deep was 5°, and at 1 foot deep as much as 9° warmer than is seasonable. A tenth of an inch of rain fell on the night of the 4th, but previous to this the weather had been perfectly dry for ten days. No rain-water has now come through the bare soil percolation gauge for over five weeks. On the first six days of the week the sun shone on an average for 11 hours a day, or for 5½ hours a day longer than usual. Calms and light airs alone prevailed. The mean amount of moisture in the air at 3 o'clock in the afternoon fell short of a seasonable quantity for that hour by no less than 26 per cent. On the 2nd the air was drier than I have ever known it here at any period of the year, the difference between the wet and dry bulb thermometers amounting to 25° at 3 p.m.

AUGUST.

An exceptionally hot, dry and sunny month. During the 20 years over which my observations at Berkhamsted extend there has been only one warmer August, and that was in 1899. On the 31st the temperature in the thermometer screen rose to 92°—making this the hottest day that I have yet recorded here in August, or indeed in any other summer month. However, since September began a slightly higher reading has been recorded. As showing the comparative coldness of the nights at this period it may be stated that only two nights previously the thermometer exposed on the lawn fell to within 2° of the freezing-point a remarkably low reading for the time of year. The great range in temperature during the last few days is shown by the fact that on one day the difference between the highest and lowest readings in the thermometer screen amounted to as much as 40° or a greater daily range than in any previous August. Rain fell on but nine days, while the total fall amounted to less than a third of the average rainfall for the month, and was smaller than in any August for 26 years. No rain-water at all came through either of the percolation gauges during the month. The sun shone on an average for 7¾ hours a day, or for as much as 1¾ hour a day longer than usual. Calms and light airs mostly prevailed, but on one or two days the wind was rather high. In no hour, however, did the mean velocity exceed 18 miles. The atmosphere continued singularly dry, the mean amount of moisture in the air at 3 p.m. falling short of the average by as much as eight per cent. On one day the difference between the readings of the wet and dry bulb thermometers at 3 p.m. was 21°—indicating a degree of dryness which has only once before been exceeded during the month of August in the last 20 years.

THE SUMMER.

Taken as a whole this was a very warm summer, but only in August was the heat very exceptional. It proved also a very dry season. June was a wet month, but taking July and August together there was a deficiency in rainfall of 3¾ inches—equivalent to a loss of 16 gallons on each square yard of surface in my garden. There was a plentiful record of sunshine in all three months, the total exceeding the average for the season by 1½ hour a day. *E. M., Berkhamsted, September 5, 1906.*

Obituary.

G. W. LAW-SCHOFIELD.—News has reached us of the death on September 1 of that enthusiastic cultivator of Orchids G. W. Law-Schofield, Esq., New-Hall-Hey, Rawtenstall, Manchester. Mr. Law-Schofield, who was one of the leading growers in the Manchester district, and whose fine productions often appeared at the Royal Horticultual Society's meetings, has suffered from declining health for the last two or three years, but took great interest in his Orchids to the last. In our issue of June 2 last, p. 339, we gave an illustration of his Odontoglossum crispum "G. W. Law-Schofield," which the deceased gentleman considered his best Odontoglossum.

ANSWERS TO CORRESPONDENTS.

AGRICULTURAL COLLEGES: *A. E. K.* You had better apply to the authorities at each college for information upon the literature they distribute.

AMPELOPSIS: *F. B.* The agent's action was unjustifiably arbitrary. Whether he had a right to cut down the plant would depend upon the circumstances which are unknown to us. Consult a solicitor.

ASTERS: *J. K. M.* The Asters may have suffered from a fungous disease or the rotting may be due to an excessive degree of wet. The millipedes sent us are in the habit of feeding upon decaying vegetable tissue, and we do not think they have caused the mischief.

BEAN: *P. M.* One of the coloured varieties of continental origin, probably Firefly.

CARNATION SEEDLINGS: *W. P. C.* None of the varieties is of special merit.

CELERY: *H. S.* The cause of injury is a minute fungus, Cercospora apii. This is a difficult pest to combat, and spraying with Bordeaux mixture is the only known preventive.

CHRYSANTHEMUM LEAVES: *W. B.* The disease is a leaf blight due to the fungus called Cylindrosporium Chrysanthemi. Spray with potassium sulphide every four days at the strength of 1 ounce to 3 gallons of water. The use of liquid manure greatly favours the disease.

CUCUMBERS: *Homeland.* The plants have been killed by over-feeding. Leave out the kainit and reduce the other substances by one half until the plants recover, as those may do that are not yet seriously injured. *J. D.* The plants are attacked with the "spot" disease, Cercospora melonis, that has been repeatedly described in our columns. Burn all the affected leaves and spray the remaining ones with liver of sulphur—½ ounce to a gallon of water, taking care not to wet the paint on the woodwork of the house. Use the same precautions at the end of the season as are recommended *J. H.* for eelworm in Melons.

DAHLIA CLASS: *F. C. S.*—The schedule is loosely worded. If we were to try to determine what was intended by the words "18 Dahlia blooms, Cactus varieties, double, 12 distinct varieties, to be shown in vases" we should probably conclude that it was intended that not fewer than twelve distinct varieties would be permitted, for if exhibitors were limited to twelve varieties and no more, why have eighteen blooms? But the judges had not to do this, they had simply to see that the exhibit was in accordance with the "letter" of the schedule. As the schedule said twelve distinct varieties were to be shown, but did not limit the number to twelve, the exhibitor who had fifteen varieties should certainly not be disqualified, whether the intentions of the compilers of the schedule were what we surmise them to have been or not.

GRAPES: *Constant Reader.* We are unable to find any disease in your specimens, and are inclined to think there is something lacking in the cultivation afforded the Vines.—*E. Y. B.* The foliage distinguished as Number 1 is disfigured by sun-scorching, and is not affected by any disease. Ventilate the house more freely and earlier in the day. The leaves marked Number 2 showed small warts or intumescence on the under side. This is due to there being something wanting in the proportion of heat and moisture of atmosphere and border. The condition will not seriously affect the Vines. The berries received appear to have slight indications of a disease known as anthracnose, but we should like to have further specimens.—*L. G. R.* We cannot offer any advice unless specimens are sent us for examination.—*A. J. C. & A. W.* The bunches are badly "shanked" and some of the berries are diseased with the "spot" fungus. Shanking is usually the result of some defect in the border which prevents the roots from properly performing their functions and thus the vines receive a check. See to the borders in the autumn and put them and the drainage material in a proper condition. Avoid overcropping the vines and thin out the growths. The berries that are marked with a depression should be cut out and burned, and the vines be sprayed next spring with potassium sulphide, ½ ounce to one gallon of water. Be careful that the liquid does not reach the paint, which it would turn black.—*W. S., Low Wood Hall.* You have evidently got an epidemic of Botrytis cinerea, which strongly suggests that there is a lack of ventilation in the house early in the day, as this fungus only infects leaves or fruit during the early part of the morning, and when there is a certain amount of moisture on the surface of the parts attacked. Spray with a rosy-red solution of Condy's Fluid to check the spread of the fungus.

IVY-LEAVED PELARGONIUM: *R. F.* The injury is caused by caterpillars. Examine the foliage at night. You might syringe the plants with a solution of Quassia Extract in water.

MALFORMED BEGONIA: *G. N.* Many thanks. We have seen similar instances.

MELON ROOT: *J. H.* The clubbing is caused by a very bad attack of eelworm. You should remove and burn all particles of the roots and stems of the plants when you have harvested the crop, and thoroughly sterilise, by baking, the soil in which they have been grown. This soil should not be mixed with the old potting loam, but had better be placed in some distant part of the garden. In the autumn thoroughly cleanse the house, using water with a little carbolic acid (POISON) in it. Do not grow Melons or Cucumbers in the same house for a season or two afterwards, if another house can be utilised for the purpose.

NAMES OF FLOWERS AND FRUITS.—We are anxious to oblige correspondents as far as we consistently can, but they must bear in mind that it is no part of our duty to our subscribers to name either flowers or fruits. Such work entails considerable outlay, both of time and money, and cannot be allowed to encroach upon time required for other matters. Correspondents should never send more than six plants or fruits at one time; they should be very careful to label them properly, to give every information as to the county the fruits are grown in, and to send ripe, or nearly ripe, specimens which show the character of the variety. By neglecting these precautions correspondents add greatly to our labour, and run the risk of delay and incorrect determinations. *Correspondents not answered in this issue are requested to be so good as to consult the following numbers.*

R. W. 2, Jargonelle; 5, Fondante de Cuerne. We cannot name the other fruits, for they are small and ill-developed.—*A. S.* Red Astrachan.—*A. W.* 6, Beauty of Bath.—*Pinehurst.* Calville Rouge Précoce.—*Milford.* 1, Clapp's Favourite; 2, Fondante de Cuerne; 3, Lord Suffield; 4, Hormead's Pearmain; 5, New Hawthornden; 6, Lord Grosvenor; 7, Keswick Codlin.

NAMES OF PLANTS: *H. N.* Mesembryanthemum species, but which one cannot be determined from the flower received.—*W. H.* 1, Echinops Ritro; 2, Helianthus divaricatus; 3, Buphthalmum speciosum; 4, Chrysanthemum Parthenium var. fl. pl.; 5, Rudbeckia speciosa; 6, Helianthus laetiflorus.—*A. W.* 1, Philadelphus grandiflorus; 2, Fraxinus sp.; 3, Phillyrea decora; 4, Cotoneaster frigida; 5, Symphoricarpus orbiculatus variegatus. Another time send the specimens when they are in flower.—*A. C. J.* 1, Solidago Virgaurea; 2, Teucrium fruticans; 3, Kerria japonica; 4, Daphne mezereum; 5, Forsythia viridissima; 6, Ercilla volubilis.—*W. K.* 1, Leucothoe Catesbæi; 2, Danaë Laurus (Alexandrian Laurel).—*Monrath.* Urospermum Dalechampii and Gaultheria trichophylla.—*A. D. W.* Acer Pseudo-platanus var. purpureum.—*L. H.* 1, Solanum, probably S. Fontanesianum; 2, Campanula isophylla.—*G. Chad.* 1, Solanum capsicastrum; 2, Daphne odorata; 3, probably Erica hyemalis; 4, Acacia armata; 5, Erica, send when in flower; 6, Euphorbia (Poinsettia) pulcherrima; 7, Eurya latifolia variegata; 8, Cassia corymbosa; 9, Abutilon Savitzii; 10, probably Salvia, send flowers; 11, Zebrina pendula (Tradescantia zebrina of gardens); 12, Achimenes, send when in flower; 13, Ophismenus Burmanni variegata or Panicum variegatum of gardens.—*Alpha.* Crinum Moorei. It is well represented in gardens, and is not an expensive bulb.—*W. C. M.* Statice sinuata; a half-hardy herbaceous plant.

NECTARINES SHRIVELLING: *C. B.* The stone has formed well enough but the trouble complained of has been caused by the fruits having been wetted when exposed to the sun's full rays, with the result that they have become scalded. The injury thus sustained would be quite sufficient to account for their dropping prematurely. No doubt an excess of moisture on the growths with insufficient ventilation was largely the cause of the mildew appearing on the plants earlier in the season.

PEAR TREE: *C. S. & S.* What you have described as silvery grey scales are the coverings made by some insect to protect its eggs. The "louse-like scales" are the pupæ cases of one of the "snowy flies" belonging to the genus Aleyrodes, from which the perfect insects (the small white flies which were seen flying away) had emerged. The "silvery scales" had nothing to do with the snowy flies. If the tree is attacked by the snowy flies next year, spray it with paraffin emulsion.

THE NURSERY BUSINESS: *H. J. M.* We cannot recommend you to commence a business the practical details of which are absolutely unknown to you. It is true that many have succeeded in like circumstances, but in such cases the success has been due to the honesty and business capacity of the manager who has directed the work rather than the financier. Your letter is sufficient evidence of your business-like character, but we think you and your friend also would be well advised to obtain a situation, for twelve months at least, in a first-rate nursery business of the type you wish to establish.

TOMATO FRUITS: *T. B. A.* These are badly attacked by the "Black Spot" fungus (Cladosporium lycopersici). Remove all fruits similarly attacked and burn them. Spray the plants at frequent intervals with potassium sulphide, in the proportion of one ounce of potassium sulphide to two and a half gallons of water. See illustration in *The Calendar of Garden Operations*, which may be obtained from the publisher of this journal, price 7½d. post free.—*A. S. & Son.*—The diseased plants should be uprooted and burned. The hard, discoloured patches in fruits obtained from other plants are caused by a lack of one of the necessary food elements in the soil. Furnish the plants with some manure that is rich in potash.

VIOLETS DISEASED: *Anxious.* The leaves are injured by the Violet disease, caused by a fungus Ascochyta violae. This has often been described in our columns. The best plan is to burn the old plants and obtain new stock from a healthy source, taking care not to plant in the same soil again. The flower you enclose is Mimulus (Diplacus) glutinosus.

WEEPING ASH: *B. R. D. & S.* The insect on Ash is the common ashbark scale (Chionaspis fraxini). It is a common and widely distributed species and is sometimes injurious to "osiers," but we have never known it to cause the death of a tree or affect the foliage in the manner that the leaves received from you have suffered. We think that the leaves are attacked by a fungus which is the real cause of the disease, but will further examine them. The scale may be easily eradicated; make an application of paraffin emulsion by means of a scrubbing brush to the stem and main branches where the scale is probably most numerous.

FRUIT GROWING IN CANADA.

THE Editor, in his remarks in the issue for July 28, seems to suggest that hybridists and cultivators should persevere more in the raising of late-flowering varieties, and endeavour to secure more sheltered situations on which to plant their orchards. The latter subject might perhaps be given more careful attention, but the choice of a site is very difficult. We often find an exposed situation, especially if it is of good elevation, more successful than a lower one with shelter, and this year it has been very much the case in this locality. As regards late-flowering varieties, such as Court pendu-plat, I have no great faith; they would, of course, have a shorter season of summer weather in which to ripen their fruits. For my own part, I would prefer to keep the varieties we have, and hope rather for some mitigation of cold during the months of April and May. Judging from what has been done in the past, scientists may reasonably be expected to do a great deal more, and we are loth to give up hope that in their respective laboratories someone may be fortunate enough to discover a clue, which may lead to giving us complete immunity from the vagaries of those frequent and destructive spring frosts.

But whilst these problematic improvements are still *in nubibus*, are we to wait cavilling over where to plant, whether we should root-prune, top-prune, summer-prune, pinch, winter-prune, or for the arrival of some long-looked-for and wished-for panacea which will carry us safely through all our pomological difficulties? Whilst we are waiting for all these much-hoped-for Utopian evolutions to come about, with often years of consecutive failures in between, our trans-Atlantic American and Canadian kinsmen, with their unlimited land areas, climatically and terrestrially adapted for high-class fruit cultivation, are extending their plantations with almost magical quickness, are pouring their fruits into our markets in unlimited quantities, for which they carry away heaps of our money, whilst we are compelled, helplessly, to stand by and see the gold flowing out of our country.

Were I a young man with the world before me, and had made up my mind to be a fruit grower, I would betake myself to one or other of those well-known fruit-growing countries, of which there are great choice, when fruits of many varieties can be grown with certain results. I have sent several young fellows to America and some to Canada, and all have done well.

The only difficulty that I am aware of which prevents others making up their mind to go is in the foolish reluctance of "cutting the painter" between the old country and friends they would leave behind. This is more imaginary than real, for in these days of quick, comfortable, and cheap passages an occasional home-coming is not beyond easy attainment; some of my friends, with their families, have been home and gone back again. Those who cannot make up their minds to go must just stay at home and continue to swell the ranks of the great unemployed, or of the miserably remunerated legions of gardeners waiting for appointments which may never turn up. One thing may be accepted as certain, namely, that there are not places for all those who are expectingly waiting for them. When a young man realises the truth of these facts and seriously considers the infinitely small chance he has of ever getting anything in this country worth waiting the best part of a lifetime for, he will then be in a position to think what he had better do with himself.

I have a little book before me, which has for its title "3,800 Miles Across Canada." It is written by J. W. C. Haldane, who graphically and instructively describes the country; it also has an excellent map, showing the country all the way through from Newfoundland in the Atlantic to Vancouver in the Pacific. This book is liberally illustrated, and so well describes the resources of the country to all whom it may concern, that anyone desirous of going thither would do well to provide himself with a copy.

Although Canada has its well-known fruit-growing belt, or zone, extending from the east side of the Dominion to that of the west, yet there are some provinces more highly favoured than others, and such an one is Ontario, of which Mr. Haldane gives the following description:—"Ontario forming as it does the very heart of the Dominion, its progress, wealth, and population entitle it to be recognised as the most important of them all. Its area is 220,000 square miles, or 78,000 more than that of the British Isles. To many it may appear strange that in a climate supposed to be so cold in winter as the adjacent Niagara district, fruit-growing on a gigantic scale could be carried on, yet so it is. Not only are Peaches, Grapes, Apples, Pears, Plums, &c., produced in enormous quantities, but so excellent are they that at the world's Colombian Exhibition at Chicago the fruit of this locality secured the greatest number of awards."

Leaving Port Arthur, on Lake Superior, a most interesting run of about 1,000 miles on the Canadian Pacific Railway, through the prairie provinces of Manitoba, Assiniboia, and Alberta, which chiefly form the Great Central Plain of Canada, the Crow's Nest Pass on the Rocky Mountains is reached, and here the province of British Columbia is entered—a country about twice the size of France. The district of this country to which I more particularly wish to draw attention lies in the south-east corner, known as the Kootenay or Selkirk country, and is watered by the rivers Kootenay, Columbia, and numerous other smaller rivers and lakes.

Mr. St. Barbe, of Nelson, in describing the advantages which the Kootenay Valley has over the rest of the provinces as a fruit-growing region, says there are two; the first is the climate, which permits the cultivation of fruit without irrigation, but if water be needed, it is everywhere available. The second advantage is nearness to market. Taking Nelson as a centre of the valley, it is thirty-six hours nearer to Winnipeg than any other fruit-growing place. The fruit is collected from each ranch by steamers, which ply continually along the lakes, and is taken by them to the railway, where it travels in a refrigerator car and arrives in perfect condition at Winnipeg, Calgary, Edmonton, or other destination. It is in consequence of its prime condition that Nelson fruit is in greatest demand.

Mr. St Barbe goes on to say:—The fruit-grower's life is an ideal one. He does not require a large extent of land to work. Twenty acres will keep a family, and it is better to begin with too little than too much. The climate is excellent; seldom does the thermometer fall to zero in winter, and rarely climbs to 90° in summer, while the rainfall, from 25 inches to 30 inches, just supplies sufficient moisture for the crops. The scenery is everywhere as fine as any in the world, and in Nelson the settler will find many of the comforts of civilisation. The sportsman will find in the waters of the lakes and rivers an abundance of trout and char. In the hills are deer, bear, and grouse. Chinese pheasants, and quail, which abound in Vancouver Island, are being introduced, while not far off are elk, moose and mountain sheep.

To a man with not less than £300 or £400, the Kootenay is an ideal place of settlement. That amount of capital will enable him to buy twenty acres of the very best land and build himself a comfortable cottage thereon. If he has a family he will find schools for his children near at hand.

In the above district all kinds of fruits common to temperate climates are raised—Apples, Pears, Tomatos, Plums, Cherries, Strawberries, Currants, &c. Strawberries are one of the staple crops. Many thousand crates of 24lb each have been shipped out this year. There is a local demand for this fruit, but its chief market is in the towns of the north-west, where the market is an insatiable one, for though the prairies grow the finest wheat in the world, they will not grow fruit.

At Vernon, about 100 miles to the north-west as the crow flies, is the 13,000-acre ranch of Lord Aberdeen, on which a few years ago there were 12,000 fruit trees.

I am afraid this paper is encroaching far too much on the valued space of the *Gardeners' Chronicle*, but I must ask the Editor to allow me to make a short quotation from an article on fruit-growing by Mr. Maxwell Smith, the Dominion fruit inspector. In the course of his paper, Mr. Smith points out that although it is less than sixteen years since the first car-load of fruit was shipped out of British Columbia, progress has been fairly rapid, and people are now beginning to realise something of its possibilities as a fruit-growing province. In the season of 1904 the fruit of British Columbia was valued at 600,000 dollars, and the area under cultivation estimated at 14,000 acres. In 1905 the area under fruit had been increased to 20,000 acres, and the total revenue derived therefrom was nearly one million dollars. In the same year something like 500,000 dollars were expended in the purchase and improvements of fruit lands. *W. Miller, Berkswell.*

FOREIGN CORRESPONDENCE.

LILIUM SULPHUREUM.

I AM sending you a photograph [see fig. 77] which was taken by Mr. C. Sprenger in his garden, near Naples, of Lilium sulphureum, which for one month was the admiration of all visitors. Liliums are not grown well generally in Naples except L. candidum, tigrinum, speciosum, and umbellatum, but this fine species succeeds here in the most satisfactory manner. Three years ago some very small bulbs were received from Upper Burmah, and were planted in a mixture of peat and loam at the foot of a wall in a half shady place with plenty of water during the summer; they have made a good growth. The first flower appeared in the second year and was identified as L. sulphureum. This year, in spite of the ashes from Vesuvius, they came up at the end of April very fast, and have now attained a height of more than two meters, the largest having eight flowers. These are widely open, waxy-white with a golden yellow throat and large crimson stamens and greenish pistil; the flower is not very fragrant, but much finer, and not so heavy as the Madonna Lily. Multiplication is rapid and easy by means of the bulbils in the leaf axils. Lilium sulphureum is one of the most beautiful flowers of its kind and a rival of Lilium auratum, but certainly of easier cultivation, and it is certain that this Burma Lily will be grown in the future in most gardens. The single flower here with a heat of 31° cent. was well open during a week, but in England it would last much longer. *William Mille, Naples.*

FIG. 77.—LILIUM SULPHUREUM FLOWERING IN MR. SPRENGER'S GARDEN, NAPLES.

ORCHID NOTES AND GLEANINGS.

MESSRS. J. MCBEAN & SONS, COOKSBRIDGE.

ODONTOGLOSSUM CRISPUM in the highest condition of good cultivation and in the finest normal and spotted varieties are the special feature in Messrs. McBean's well-managed nursery. From the first Mr. A. A. McBean, who specially attends to the culture of the plants, seems to have understood their requirements, and success attended his efforts throughout until now when the Cooksbridge culture and stock is generally admitted to rank with the very best in the whole world. Success in growing Odontoglossums depends largely on providing suitable houses for their accommodation, and in this particular Messrs. McBean were careful, and their improved methods of arrangement have been reported on several times in the *Gardeners' Chronicle*. Briefly, it may be said that their houses are well ventilated, without being "draughty"; rain-water tanks of great capacity are provided in the base, for rain-water is one of the chief necessaries in Orchid culture; the floors of the houses are of natural earth surfaced with ashes and with teak trellises for walks, and the staging is constructed in the best style, so that each plant has the benefit of fresh air all around it just as if it were suspended. The framework of the staging is put together on the place from "angle-iron" and "T" iron, which can be purchased in quantity and set up on iron standards with water-holding saucers at the bottom to assist in keeping insects from the plants. In the larger houses there is a central, skeleton iron stage of four tiers, the lower ones being only wide enough to take a single row of plants, and the top part several rows. There is a staging of similar construction all round the interior of the house. For the accommodation of the plants red tiles used to be placed on the iron staging, but these Messrs. McBean have now discarded in favour of teak bars 2in. by 1in., and which are cut to fit the parts of the staging on which the plants are to stand and are always movable and adjustable to suit the size of the plants to be placed on the stage. Thus in the lower rows of the central staging for single rows of plants the teak blocks are only 6in. or so in length, and two of them are allowed for each plant, the air from beneath consequently circulating all round it almost as freely as if suspended. There is another reason for the use of teak instead of tiles, viz., that in Mr. McBean's opinion the teak staging is not so cold in winter.

For the purpose of shading lath blinds are used, with an additional thin net or tiffany shading over the lath blind on the sunny side. There are many important points in the arrangement of the Orchid houses at Cooksbridge which would be of the greatest importance to some who are not so successful in their culture, and Messrs. McBean are always pleased to assist others to the benefit of their experience.

The stock being so great the operation of potting, which is now in full swing has to be carried on more or less throughout the whole year: July, November, and December being the months in which only absolutely necessary potting is done, the main potting being completed if possible by the end of September. For potting material good fibrous Orchid peat and sphagnum-moss are still held to be the best, but experiments are being made with Polypodium fibre. Broken flower-pots or "crocks" for the bottoms of the pots are not used, but sterilised bracken rhizome is utilised instead.

The affording of water is one of the most important matters. If the plants are over-watered, as they unfortunately are in many collections, they root imperfectly. The Cooksbridge Odontoglossums never look wet, for as soon as watered the superabundant moisture passes away. They are not, however, allowed to get dry, but are carefully picked out and watered before that stage is reached. Plant after plant which Mr. McBean turned out of the pots for an inspection of the roots showed the pots full of them, the older roots being still white and healthy while the new ones are forming.

But to return to the plants. The same health characterises the whole of them, and in every house the same great sleek bulbs and spotless fleshy green leaves are to be seen. Many of the specimens in the larger houses are of enormous size, and the tale of their progress in many cases is interesting; but the best evidence of success perhaps is given in the case of fresh importations which rapidly assume the appearance and size of old-established plants. A pleasant example was seen in a batch imported in 1904, but which could not be distinguished from the plants of much earlier importations, the 1904 plants having two or three fine leafy pseudobulbs and new growth again forming.

It is not the O. crispum season of flowering yet, still there were many very handsome forms in flower, although seventeen dozen spikes were said to have been cut on the previous day. The spikes in many cases bore fourteen or fifteen fine large flowers, the typical white or blush-tinted varieties predominating. The same appearance of extraordinary size and vigour characterised all the plants, and especially in the three largest span-roofed houses, one of which has the side staging filled with selected varieties both white and blotched, many of which have already made a stir in Orchid circles, while yet others have not been publicly shown. Among the former are the famous O. crispum "Persimmon," now in bud; O. c. Pittianum, O. c. Abner Hassel, O. c. Annie, O. c. Lindeni, with three leading growths; the marvellous O. c. F. K. Sander, and representatives of most of the best blotched forms; while among those which have not yet made their *début* are several of which drawings had been made, and which should take high rank.

Some of the plants in the select division are not the property of Messrs. McBean, but have been entrusted to their well-known skill by some of the leading Orchid amateurs. The central row in some of the houses is of Oncidium macranthum, which produces enormous pseudo-bulbs and a great profusion of flowers. One then in bloom was the fine O. m. hastiferum, and another had a spike only about a foot in height and with four very large flowers of a clear Buttercup yellow with sepia brown tint on the sepals. Odontoglossum Edwardii does equally well, and patches of finely-grown Cochlioda Noezliana, Odontoglossum Harryanum, O. luteo-purpureum, and O. Pescatorei of a very fine type, were noted. In one of the houses a distinct form of Odontoglossum crispum with the lip almost entirely reddish-purple, after the manner of O. c. roseum and with spotting on the sepals, was remarked.

SEEDLING ODONTOGLOSSUMS.

Messrs. McBean have lately taken up the raising of hybrid Odontoglossums, and already a small batch is approaching the flowering size, while many thousands are in the germinating and store-pot stage. The crosses have mostly been made from finely blotched O. crispum on the one side, and on the other some species likely to give a novel combination. The seeds are sown on the surface of the compost around plants of ordinary O. crispum, which are simply suspended near the glass of the roof and they germinate freely.

THE INTERMEDIATE HOUSES.

Specialities other than Odontoglossums are to be found in the warmer houses, in one of which is a large quantity of chiefly white forms of Lælia anceps, L. a. Schroderiana predominating. Among the coloured forms the superb L. a. Fascinator, which secured an Award of Merit at the Royal Horticultural Society, is the finest. A large batch of Cattleya Dowiana aurea had quite three-fourths of the sturdy plants with flower sheaths, and a fine lot of C. Trianæi, including a plant of the white C. T. Amesiana, were equally good. A stage in this house contained vigorous specimens of Cymbidiums; also of Dendrobiums in many rare varieties; Lælias and Lælio-Cattleyas, some few in flower; Oncidium incurvum with many spikes; Cattleya Schroderæ, a batch in sheath; some good Brassi-Cattleyas, and a vigorous lot of Cypripediums, with a fine C. triumphans; a very handsome cross between C. Argus and C. Harrisianum superbum, and a few others in bloom, including a large specimen of C. Lord Derby, and a good one of C. James II. Veitch.

Of plants other than Orchids noted were a large batch of finely-coloured Saxifraga sarmentosa tricolor, some handsome specimens of the white-variegated Dracæna australis Doucetii, some well-furnished Araucaria excelsa, and nice plants of the handsome Asparagus myriocladus.

FIG. 78.—THE PRIMULAS OF CHINA: WILD PLANT OF PRIMULA SINENSIS COLLECTED IN ICHANG BY DR. HENRY.

THE PRIMULAS OF CHINA.

As is known to plant-lovers generally, the genus Primula belongs essentially to the temperate regions of the Old World. Messrs. Pax and Knuth, in their recent monograph enumerate 208 species, and two others are given in the addenda. Of these 210 species, no fewer than 201 occur in Europe and Asia. Of the remaining nine, seven are found in North America, one (P. imperialis) in Java, and one (P. simensis) in Abyssinia. The latter is by some authorities considered to be only a form of the Arabian P. verticillata.

An analysis of the distribution of the Old World species, shows that 76 species are endemic in China, 46 species in the Himalaya, 31 species in Europe, and 10 in Japan. The remainder are scattered from Asia Minor to Afghanistan, and throughout Central and Northern Asia. Six species (P. Listeri, P. denticulata, P. nivalis, P. involucrata, P. sikkimensis, and P. geranifolia) only are common to China and the Himalaya, and one species (P. Forbesi, see fig. 79), is found in Yunnan and Upper Burmah. Three species (P. algida, P. sibirica, and P. farinosa) are widely spread in Northern Asia, and forms of these extend to the Chino-Himalayan regions. Two species (P. borealis and P. farinosa, see fig. 80, p. 193) extend practically all around the northern regions of the world, while a form of P. farinosa is isolated right away down in the mountains of Patagonia and the Falkland Islands. But, perhaps, the most astounding fact of all is that no species of Primula is common to China proper and to Japan!

As I have elsewhere (see *Journ. R.H.S.*, vol. xxix., part 1, p. 657) indicated, the popular belief that the floras of China and Japan are one and the same is erroneous. Later I hope to substantiate this with proper details and analyses. For the time being it is sufficient to draw attention to the remarkable fact of the dissimilarity in the species of Primula from the two regions.

With 129 out of the 210 species recorded in Pax and Knuth's monograph, it will at once be seen that the headquarters of the genus is to be found in the wild and rugged regions of the Indian and Chinese Alps. The European groups to which the common Primrose, Cowslip and Auricula belong are not represented in China. In fact, leaving aside the *Farinosæ*, no group of European Primroses has representatives in the Chino-Himalayan regions.

Until comparatively recently, China's wealth in species of Primula was entirely unsuspected;

and the same is true of many other genera. It is to those unselfish and indefatigable workers for science Pere David, Pere Delavay, and Dr. Augustine Henry—that we owe our first real knowledge of the marvellously rich flora of Central and Western China. Pere Delavay was the first to discover and make known 50 per cent. of the Primulas at present recorded from China! During his own wanderings in China, the present writer collected some 50 odd species of Primula. A large percentage of these are new to science, but only those that have flowered under cultivation have as yet been described. Five of these new species are taken up by Pax and Knuth, and to these must be added four others, making a total of 85 endemic species at present recorded from China.

With the exception of P. Maximowiczii, which is found in the neighbourhood of Peking, we have no record of any Primrose occurring in China east of Ichang (long. 111° 30′ circa). However, it will be passing strange if the botanically unknown mountains of Hokien and Hunan do not yield species when properly investigated. Even in Central China comparatively few (13) species have been found. Indeed, whilst the genus is widely spread in China, and ranges practically from the sea level to the limit of vegetation, the great concentration of species occurs in the highlands of the extreme west. With certain exceptions, the Chinese Primulas are very local in their distribution. For example, P. sinensis is confined to the limestone cliffs in the immediate neighbourhood of Ichang (see fig. 78, p. 191), but P. obconica extends from Ichang westwards for a thousand miles. These two species also occur at lower altitudes than any other species of Chinese Primula, Ichang being only 129 feet above the sea-level.

The altitudinal limits of any one species is usually sharply defined, and it is most interesting, when traversing the mountains, to note how one species displaces another as any considerable ascent is made. The order of their appearance is first an odd plant or two leading up to the ascent to a vast colony at the altitudinal optimum. Above this point the numbers dwindle, and finally the species disappears and another puts in an appearance. In various parts of this country thin woods carpeted with Primroses and meadows with Cowslips are common and familiar sights. Only by keeping such sights as these in mind is it possible to appreciate the colonies of Primulas in Western China.

As hinted above, Primulas are essentially social plants, forming at their altitudinal optimum vast colonies to the partial exclusion of other plants, and, when in flower, often constitute a dominant feature of the vegetation. In the Alpine regions of Western China, which are simply a continuation or extension of the great Himalayan Alps, Primulas are rampant. I have walked for days through woods carpeted with the lovely violet-purple flowered P. ovalifolia and P. sonchifolia, and Alpine meadows ablaze with colonies of various species. A Primula (P. obconica) was one of the first plants to greet me on my arrival at Ichang and in Eastern Tibet, at 16,100 feet above the sea, on a spur of a virgin snow-clad peak, a Primula (P. dryadifolia) was the last plant I could find on the blue quartzose and granite boulders of a moraine.

The colours of the flowers, and especially in the Alpine species, are usually vivid and intense. They range from soft yellow, through the varying shades of pink, red, and purple, to the loveliest of blue. And the delicate fragrance of many I might say majority adds a further charm. *E. H. Wilson.*

(To be continued.)

FORCING FRUIT TREES IN POTS.

(Concluded from page 184.)

Time of Beginning to Force.

In our case, we place a few trees (Nectarines only) into a house that is closed about December 1. This is done in order to secure a few dishes of fruits, if possible, in advance of the first early house, in which the trees are started about the middle of the same month. In such a house as the latter, three or four, or even more, varieties can be started, so as to form a succession. This year we have worked our extra early Nectarines through the vineries, first in the first early, then in the mid-season, and afterwards in the late vinery for ripening; this has answered very well, but I do not advise too many trees to be so treated. Our Cherries are never really forced artificially, being under glass the buds naturally develop earlier than they would if out of doors. Then we commence to keep the atmosphere of the house close, but do not employ fire heat until the fruit is fairly set, so long as we can be sure of the atmospheric temperature of the house not falling below 37°, or 5° above the freezing point. We never quite close the Cherry house at all unless it is very severe weather indeed, and never close it in any case when there is a little warmth in the water pipes. Cherries are most impatient of any excitement at any stage until the stoning is completed. In our Cherry house we can keep a buoyant atmosphere by having both side and top ventilators open. For Peaches, Nectarines, and Plums, we keep a lower average, night temperature than is usually recommended. This allows of a wider range between the minimum at night and the maximum by day. This is the only variation made. I would rather see the temperature indicated on our thermometers a degree or two below 40deg., than for the record to be nearer to 50 deg. when the trees are in full flower, i.e., the first thing in the morning. In the home of the Peach (Persia and Eastern Asia) the night temperatures are low, even in the earlier part of the summer, and long after the fruits are set. In the day time, however, it is known to be uncomfortably warm. We get this condition in our own case by closing the house early when the weather is favourable.

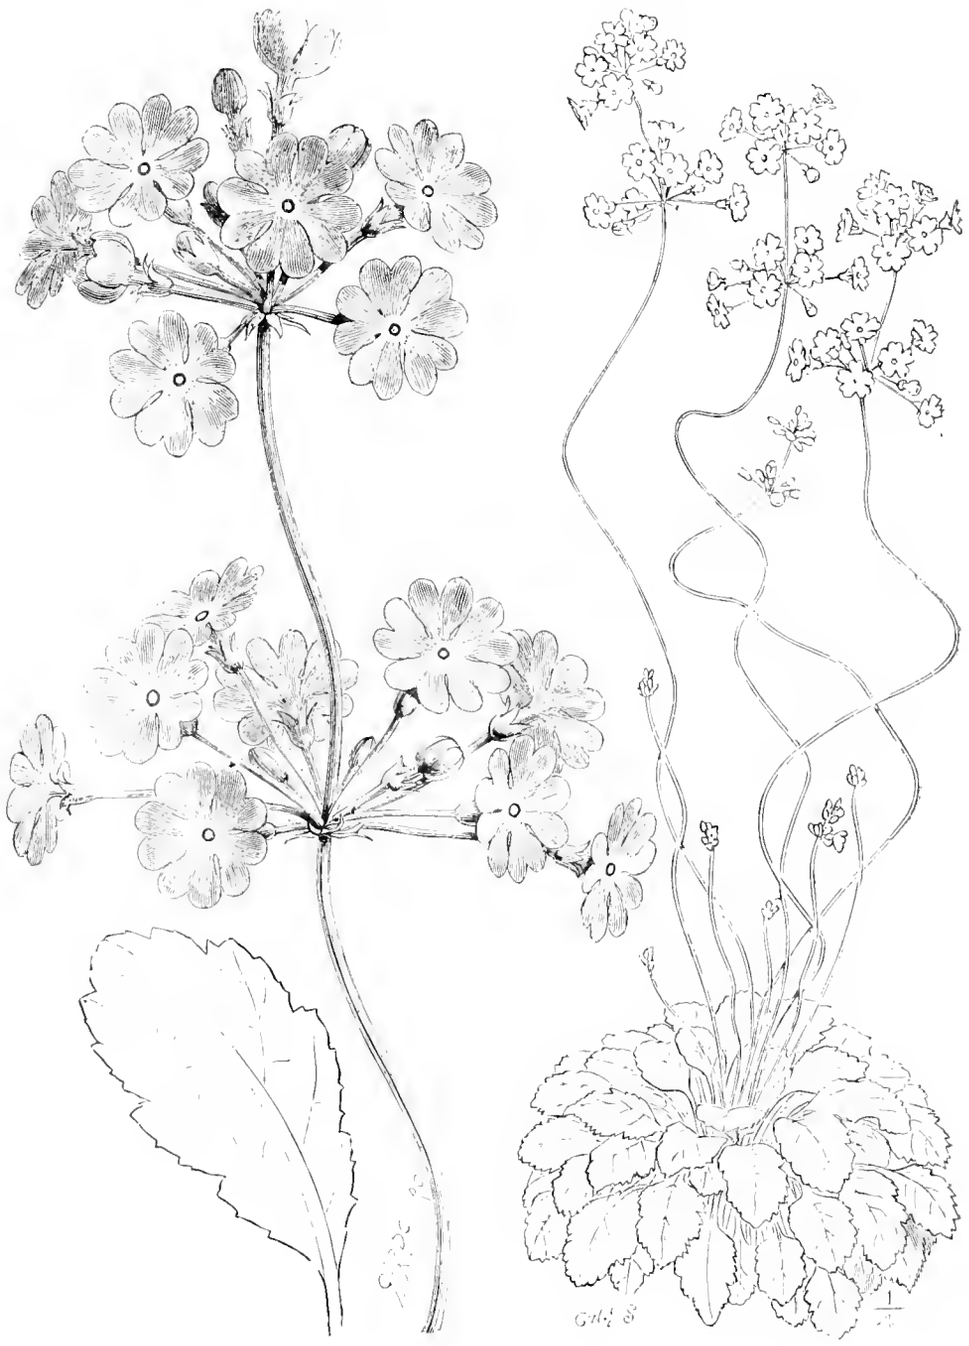

FIG. 79.—THE PRIMULAS OF CHINA: P. FORBESII.

POLLINATION AND FERTILISATION.

As all fruit growers know, this is the anxious time in the cultivation of fruit trees under glass, but not to such a degree as out of doors, in the kind of weather we experienced last spring. Formerly we depended upon the careful manipulation of the pollen masses by means of a camel's hair brush or of a rabbit's tail. We have discarded these means now and adopt what is no doubt an older plan, which is as follows: we have a hive of bees in each house when the trees are in flower, and find this to answer admirably. Upon a fine day it is a pleasure to see the bees actively employed in their work; in the Cherry house they seem to be specially at home and busiest of all. Until we resorted to bees for effecting pollination, we could not secure a good crop of Early Rivers Cherry, but now there is no difficulty. Perhaps on this point the experience of others may be different.

PRUNING.

We adopt a different system with trees in pots to that we practise on those planted out. We do not prune, save to a slight extent, either Peaches, Nectarines, or Plums, whilst the trees are dormant. We prefer to prune, so much as may be required when the fruit is set; this dispenses with and takes the place, almost perfectly, of the well-known process of disbudding. If the object be to make a pot tree as large as possible, less pruning and more disbudding would be better. There will not be any over vigorous, or very sappy, shoots to be dealt with under pot culture. It is an easy matter to regulate the branches by tying as occasion may arise. In doing the pruning care is exercised not to leave any wood above the bud that can die back. We prune close to the bud and the wounds eventually heal over. Pinching is done when the shoots get to a moderate length, and according to the particular tree being dealt with—usually from 6 to 9 inches. Of course, by pinching the stronger shoots first, more strength is thrown into the weaker ones. In making or building up a tree of pyramidal shape, a leader must be secured; this can be kept in position with a slight stick fixed to the stem. In some instances a stake is of use to support or keep the tree in a good shape.

RIPENING AND GATHERING.

As the fruits commence to develop a fairly good colour, syringing is discontinued. This can be done with greater safety in the case of pot trees, because throughout the growth up to that period it is easier to ply the syringe to every part of the tree than it is in the case of trained trees. There is also another reason for discontinuing the syringing early, viz., to guard against any tendency in the fruits to crack or split. For instance, in the cases of Cardinal, Early Rivers, and Lord Napier Nectarines, this will sometimes occur; as a case in point, during two or three wet or dull days, when the final swelling is in process. Perhaps syringing has been done early in the morning and the moisture has clung to the trees for some considerable time. This will induce splitting and thus disfigure the fruit. Most fruit growers have noted, no doubt, that Lord Napier Nectarine has a peculiarity at times of assuming a rusty appearance. In my opinion it is caused by this excess of moisture, with possibly a sudden outburst of sunshine upon it. Cardinal Nectarine, it should be noted, is not recommended as a trained tree out of doors. I think it is the tendency to split that is the cause of this. Under pot culture, by exercising care, we have no trouble at all with this variety.

In gathering the fruits from our pot trees we adopt the plan (in order to avoid any bruising at the base of the fruit) of snipping off each fruit carefully with a pair of Grape scissors. There is a tendency in the case of trees in pots for the fruits to swell hard back upon the stem. It also occurs in the case of trained trees, and is specially noticeable in Early Rivers Nectarine. Now, if these fruits are twisted even in a slight degree some amount of bruising must ensue. By the use of a strong pair of vine scissors this is completely obviated. In any case it is better than taking the fruit completely into the palm of one's hand, with the possibility of inflicting a bruise.

TREATMENT OF TREES AFTER FRUITING.

As soon as the fruits are all gathered the houses are freely ventilated, and after a few days of this treatment the trees are ready to be turned out of doors for the summer season. A position that is moderately exposed is better for this purpose. In order to save some amount of watering during the warm weather the trees are all plunged to the rim. There need not be any fear in doing this for the pots will be full of roots, and the beneficial effect of the plunging will be apparent in the amount of young roots that will have made their way into the soil. When the trees are lifted in the autumn, we place them somewhat more closely together than when under glass and keep them loosed or syringed frequently.

CROPS TO FOLLOW.

Crops in succession may be easily varied to suit every individual case. We follow on with later trees in pots, also largely with Figs in pots, with Melons, Tomatos, and later still with Chrysanthemums. No house that is devoted to pot fruit trees need be empty any longer than it takes to give it a cleaning down. From start to finish, the pot trees that are forced will take up about seven months, thus there will be abundance of time to have first a crop of Tomatos or Melons, and then the November Chrysanthemums.

INSECT PESTS.

These are the same as in any other phases of fruit tree culture, but so far as my experience serves me, insects are not so troublesome from the reason I have already given, viz., the accessibility of the trees to the beneficial effects of the syringe. We make it a rule to fumigate the house as soon as the trees are stood out for forcing, and again before the flowers expand. Thus, various forms of aphides are kept in check. Red spider rarely if ever causes any trouble, nor does the maggot in the Cherries; the syringe stops the former and fumigation the latter.

TIME TO START FRUIT CULTURE IN POTS.

The best time to start with fruit trees in pots is the autumn when the trees can be selected to suit any given case as regards height, &c. See that they are well ripened and promising well for a crop. If these are received from the nursery by the end of September the potting can then be done early in October. In dealing with fresh trees do not be induced to defer the potting for a season, rather reduce the balls and pot afresh into pots of the same size. *Jas. Hudson, Gunnersbury House Gardens, Acton.*

FIG. 80.—THE PRIMULAS OF CHINA: P. FARINOSA.

(For text see page 191.)

NOTICES OF BOOKS.

A FIRST COURSE IN PRACTICAL BOTANY, by G. F. Scott Elliot. Blackie and Son.

PRACTICE must sink into ruts and grooves unless moved onwards by theory, whilst theory without something practical at the back of it can be of no advantage. The book before us opens with an aphorism which supplies the clue to the whole of its contents. It is, we are told, the result of five years' continuous trials at the Glasgow and West of Scotland Technical College, during which a combined course of flower study experiments, microscopic work, and explanation has evolved itself. The earlier chapters are devoted to the selection and collection of plants and other objects which may be required later on, and comprise hints as to the acquisition of microscopes and other apparatus. These materials provided, an ordinary flower is taken and its parts indicated. Before this information can have been digested the reader is informed that "the primæval flower was of a very different character. It consisted of a long stalk, with green leaves arranged one above another in a spiral, like ordinary leaves on a branch. The uppermost of these leaves carried on their edges female reproductive bodies or ovules; those in the middle carried male spores, also on the edges; whilst the lower were like ordinary leaves." This is commencing at the beginning, but to make the student plunge into the prehistoric before he can have grasped the actualities of the present, seems a questionable procedure. The book is clearly more suited for the teacher than

for the novice. The personal explanations that a competent instructor should afford his class would be a valuable addition to the information contained in the book. As early as the "third day" the student is introduced to the intricacies of nuclear division to chromosomes, centrosomes, and other minutiae which only an advanced student can hope to see for himself. For 25 "days" the author goes on explaining the morphology and mode of life of plants, with numerous illustrations and copious bibliographical references. No doubt the pupil who systematically follows the directions here given, especially if, as we have said, he has the advantage of the constant help of the teacher, would acquire a very extended knowledge of plants and of plant life.

But at the end of it all he would be forced to appreciate how very limited is the extent of his knowledge. "We must," says the author, "read, experiment, use the microscope, or, what is far better, our own eyes, and in the open air, but it is also a duty to think, and a very little thought reveals an insoluble mystery everywhere . . . the simplest fact in the life of the commonest weed is essentially as mysterious as ever." This is, no doubt, true, but it is not encouraging to the student, who requires to be assured that, although he cannot expect to comprehend the whole truth, his labor is not in vain, but that every step forward that he makes will in one way or another be of substantial advantage to him.

LE CAOUTCHOUC EN INDO-CHINE. (Rubber Trees in Indo-China) Par Camille Spire and A. dré Spire. Paris, Challamel.

THE production of rubber is of such vast commercial importance that it is no wonder that scientists and cultivators are alive to the necessity of obtaining full information as to the sources of supply and the methods of cultivation appropriate to particular species and varying climatic conditions. The book before us is written mainly by two brothers, one of whom is responsible for the botanical details, the other for the industrial and commercial portions. The country dealt with includes Cochin China, Cambodia, Tonkin, and other territories under French influence. The species described belong, for the most part, to the order Apocynaceæ. Botanical descriptions, including anatomical details, are given, and the book is illustrated by 35 plates. The latter portion of the volume is devoted to the chemistry of the subject, the method of collecting and preparing the latex, and to commercial details. The book is well got up, with ample facilities for the reader in the shape of indexes and tables of contents, so that it forms a valuable addition to the already extensive literature of the subject, the more so as it deals with a country comparatively little known to other than French explorers and men of science.

THE NEW EARTH. A Recital of the triumphs of modern agriculture in America, by W. S. Harwood, New York. The Macmillan Company.

THIS is a very readable account of what is being done by the Department of Agriculture in Washington and the several agricultural stations in the United States. If it were not written in such a "high-falutin" style, we might imagine shall we say guess?—that the book might fulfil the very useful purpose of making known to the general public the general trend of cultural science and its application to practice, but we fear the pen of a ready writer will in this case fail to carry conviction. What would an ordinary market gardener or "truck-farmer" think when he reads such a passage as this (p. 10)—"Then the soil for his Lettuce and Peas and Beans and Onions and Radishes must be of a certain well-defined structure. It must have at least one billion nine hundred and fifty millions of particles in a cylinder one-fourth of an inch in diameter and half an inch long, the little cylinder thimble, the approximate measure of a gram." Some vegetables will require two billion additional particles in each "gram" of soil, whilst if he is to grow Wheat he will require ten billion two hundred millions of particles, and so forth. Far be it from us to attempt to dispute the accuracy of these figures: we admit that they are far beyond our powers of computation. Then we have a chapter on soil inoculation, which has not yet proved a complete success on this side of the water. A section on the breeding of a selection of Wheats follows, but, in view of the recent Hybridisation Conference and the discussions thereat, it is not necessary for us now to follow our author. Insect-pests and weeds next come under review, and then a whole chapter is devoted to Luther Burbank and his work, "Greatest of All Plant Breeders." We are ready to believe that Mr. Burbank has worked on an unusually large scale, and has achieved, as such a worker must do, some important results, but the extravagant laudation that has been bestowed upon him has naturally led to a certain amount of scepticism. His methods are not new: they are the same as have been followed, and are made use of by all our seed-farmers and experimenters. Moreover, the few results that have as yet been seen on this side of the Atlantic do not justify the high-flown language which has been used concerning them. We have heard it said that Mr. Burbank himself is averse from self-seeking and notoriety, and that the adulation bestowed upon him and his works is distasteful to him. If this be so, it is a pity he does not save himself from his friends, and give to the world a plain statement of what he really has done and of what he hopes to do in the future. In existing circumstances it looks as if sometimes Mr. Burbank's name was attached to productions for which he is himself in no way responsible. If that be so, that is another reason why he should protest against the improper use of his name. Other chapters in this book are devoted to horticultural progress, forestry, dairying, husbandry, the work of the Agricultural Experimental Stations, &c. The writer, as we have said, has a fluent style, which makes his book easy and pleasant to read, but it would carry more conviction to his readers if the style were a little less ornate.

The Week's Work.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower to Sir TREVOR LAWRENCE, Bart., Burford, Surrey.

Odontoglossums.—Much time will be required during the next few weeks in carrying out the necessary repotting, &c., of the cool-growing Odontoglossums. September is the best month in the year to disturb their roots, as during the following period of cool nights a very suitable atmosphere can be maintained in the house, which is of the greatest assistance to each plant in getting thoroughly established before winter. Many of the young growths which have started will soon produce new roots, and having fresh compost will quickly get over the operation. At the present time some plants have flower spikes, and others have not yet started to grow; these should not be disturbed at this season, deferring the repotting until the new growths have made sufficient progress to produce roots from their base. These remarks apply chiefly to those of the O. crispum section, and to such well-known species as O. Harryanum, O. Hallii, O. luteo-purpureum, O. Pescatorei, O. triumphans, &c.; also to many hybrids which have been raised from these and other species. It may be advisable to caution beginners in Odontoglossum culture against using pots that are out of proportion to the size of the plants, as over-potting generally ends in failure, especially if at any time there is overliberality in regard to affording water at the root. The pots used should be quite clean and dry, and they should be drained to about one-fourth of their depth with clean crocks or pieces of well-dried fern rhizome, which have been taken from the peat. Over this a thin layer of rough moss should be placed to make the drainage secure. A suitable compost for these Odontoglossums consists of good fibrous peat and freshly-gathered sphagnum-moss in equal proportions. Mix it together in a rough state and then with a pair of shears cut it up, but not too finely. A little leaf soil may be added according to the discretion of the cultivator; also a moderate quantity of small broken crocks and coarse silver sand. When preparing the sphagnum-moss pick out all leaves, grass, and other rubbish, and closely examine it for slugs and snails; should any of these insects be found, wash the moss thoroughly in tepid rain water; by this means many eggs will be got rid of which are unseen by the naked eye. Pot the plants moderately firm, keeping the base of the young growths just below the rim of the pot, and when the operation is completed, prick in a few heads of living sphagnum-moss over the surface. For a few weeks after repotting it is advisable to water the plants very sparingly, applying it through a fine rose-watering can, and giving only just sufficient to induce the moss to grow; a decidedly moist atmosphere should be maintained, and as much fresh air admitted to the house as possible, especially when the external atmosphere is warm and moist. Carefully shade the plants from all strong sunshine. Any old plants which are unhealthy should be turned out of their pots, the roots well washed, and all dead parts removed; they should then be repotted into pots just large enough to hold their roots. Such weak plants require to be managed much in the same way as imported plants, keeping the atmosphere surrounding them as moist as possible, and affording but very little water to the roots; they will also require more shade than those which are in a sound, healthy condition.

Propagation.—When repotting the bulbs of the plants, it is not necessary to allow more than two or three back pseudo-bulbs to remain on each leading young growth; the old pseudo-bulbs that are removed may be placed in crocks or laid upon damp moss, and some of them will produce growths, after which they may be repotted. Where it is desirable to increase the stock of some special or valuable variety, the plant should not be disturbed by repotting unless it is absolutely necessary, and in such a case the less the roots are disturbed the better. If a plant, for instance, has four pseudo-bulbs, the rhizome may be severed between the second and third bulbs, leaving two bulbs on each piece. The back bulbs, if plump and healthy, will soon produce a new growth, and when young roots appear the plant may be removed and potted separately.

PLANTS UNDER GLASS.

By B. CROMWELL, Gardener to T. SUTTON TIMMIS, Esq., Cleveley, Allerton, Liverpool.

Caladiums.—As the foliage shows signs of dying away, so should the supply of water at the roots be decreased until the bulbs are thoroughly matured. It is important that the plants going to rest should be ripened off in the sun; the bulbs thus treated show a marked difference when started again in the following spring to those which matured, so to speak, under the shade of other plants. When the foliage has quite dried away, and not till then, place the plants under the stage in a house where the atmospheric temperature is not lower than 60°, taking care to put them where no drip will reach them.

Achimenes.—Remove these from the conservatory as they pass out of flower, and place them in pits where they will be fully exposed to sunshine; gradually diminish the amount of water until the foliage has died away, after which place the pots on their sides and keep them in an atmospheric temperature that will not fall below 55°.

Bouvardias that have been planted out during summer should be prepared for potting up by cutting round the roots of the plants with a half-round trowel a few days previous to lifting. After such treatment, the plants will not suffer so severe a check. When the plants have been potted, keep them in a shaded pit in an atmospheric temperature of 50° to 55°. Syringe them freely until they have become established in the new soil.

Begonia Gloire de Lorraine.—The leading shoots should be tied to very neat sticks, unless the plants are intended to be suspended in pans or baskets, for which purpose they are well

adapted. If cultivated in baskets, such baskets should be lined with wood-moss to screen the wires. One plant may be placed in the centre of the basket and three other smaller plants should be put around the sides, and they will then droop over. Syringe the moss frequently, and stimulate the growth of the plants by a weekly application of manure and soot water. The atmosphere of the house should be kept moist, otherwise the foliage will become hardened, and assume a rusty appearance on the under sides of the leaves.

Codiæums.—If these are propagated during the present month and kept in small pots during the winter, they will make excellent plants for table decoration or for grouping next summer. Select only the very best coloured shoots for this purpose. I attach much importance to the careful selecting of thoroughly matured wood with an even blend of the rich colours in the cuttings when they are taken from the parent plant; the chances are that the high colouration will be maintained in the future life of the plant, whereas from immature cuttings there are seldom deve'oped those rich tints which are so much admired. The cuttings should be immersed in a tank of water for a few hours previous to insertion in small pots; this will clean them from any red spider which may be lodged in the corrugated leaves (especially in the narrow-leaved section), and cause the leaves to absorb a certain amount of moisture, which will materially assist in keeping the cuttings fresh, without having to maintain an undue amount of atmospheric moisture in the propagating pit, which in dull weather has a tendency to cause the tips of the leaves to decay.

FRUITS UNDER GLASS.

By T. W. BIRKINSHAW, Gardener to Lt.-Col. SIR CHAS. HAMILTON, Bart., Hatley Park, Bedfordshire.

Plums.—Fruits of early varieties under glass have now all been gathered, but the mid-season and later kinds will be yielding a supply which will be appreciated, as the crops outside are, in most places, very thin this season. Ventilation must be freely provided so that the trees will receive an abundance of fresh air about them both during the day and the night-time. They must not be allowed to suffer from lack of water at their roots. Continue to damp all available spaces in the house, but avoid wetting fruits that are ripe or ripening.

Cherries.—Trees that have finished fruiting should be freely syringed, in order that the foliage may be kept clean and healthy. See that the roots are well supplied with moisture, giving manure water occasionally, as this will greatly assist the trees.

Melons have done remarkably well this season, and the recent tropical heat has hastened the development of later batches. It has been necessary to afford them temporary shade during the day-time to prevent the foliage from scorching; but they will not require this protection any longer. Care will be necessary from now, onwards, to obtain the best flavour in the fruit. The temperature while the fruits are swelling should range from 70° to 80° during the day-time, with 65° to 70° at night. Stimulants should be given about twice each week. Mildew sometimes attacks the plants, and should it appear it can be checked at once by dusting the foliage with sulphur. Plants that are showing fruit should have their foliage well thinned out, and their blooms pollenised daily. When they have "set" give each plant a top-dressing of some rich material, and close the house in which they are growing early in the afternoon.

Melons in Frames.—In some gardens the only means of growing these fruits is in frames, but with careful management good-sized and well-flavoured fruits can be obtained in these structures. In the case of frames on manure beds, care must be taken that water is not given to excess. Less ventilation will suffice after this date, and as the nights become cooler, it may be an advantage to cover the frames with mats. Maintain a temperature as nearly as possible the same as that given for Melons in houses. Close the lights early to conserve the sun's heat as much as is possible.

Pines.—The fine, open, sunny weather of this summer has been in favour of these fruits. Pines that are now finishing their ripening should be kept drier at their roots. Ventilation must be carefully afforded frames in which young plants are growing, and cold draughts must be prevented as far as is possible. Towards the end of the month it may be necessary to place mats on the frames at night-time to afford additional protection. Plants, either in or out of pots that have few or no roots should only be slightly watered, and be sprayed at closing time on fine, warm days only. Bottom heat, provided by means of fermenting materials, will be found difficult to maintain at the requisite temperature, and the bed will require frequent additions and renewals of the fermenting materials. Suckers should be rooted as they become ready.

THE FLOWER GARDEN.

By HUGH A. PETTIGREW, Gardener to the Earl of PLYMOUTH, St. Fagan's Castle, Glamorganshire.

Propagation.—The propagation of next year's stock could have been started quite a month ago, but in few places can the work be commenced in earnest much sooner than the present time on account of disturbing the beds and borders. The work should now be pressed forward without delay. Pelargoniums can be rooted either in shallow boxes, or in 6-inch pots, in which the cuttings can be inserted moderately thickly. Care must be taken to apply water sparingly, as at this time of the year dampness at the surface of the soil must be guarded against, and very little watering will be required until the cuttings are rooted. A sandy, open soil, and not very rich, with a warm, moving atmosphere, and cuttings not over succulent, are essentials to success in propagating these plants. Of new bedding varieties tried this year "King Edward VII." is by far the best, and in the darkness of its crimson flowers, the profuseness of its blooming, and its sturdy habit, it excels "Henry Jacoby," which it much resembles. Though for general bedding purposes raising seedlings of the bedding Lobelia in February is to be commended, it is often advisable for special purposes to raise plants from cuttings for the purpose of propagating from them early in the spring, and now is a suitable time to insert these in boxes. Another good plan is to pot a number of desirable sorts as stock plants for spring propagation. Mrs. Clibran, a variety having a good habit, and flat, dark blue flowers, is an excellent kind for carpet bedding purposes. The new double-flowered variety of Lobelia is certainly an acquisition, and is readily propagated by cuttings throughout the winter. It has rather strong growth and before being planted in the beds it should be starved in small pots, which will cause it to flower profusely. Verbenas may be propagated as soon as suitable growths can be obtained. The cuttings should be inserted in small pots and be given a little bottom heat. As soon as they are rooted they should be given cooler treatment. The best means of increasing the Verbena is from cuttings in the spring, for which purpose it is necessary to have store plants in pots. These stock plants should now be pruned closely and be afterwards given a shift into larger pots containing rich soil. They should be kept in a cool house through the winter, and in the spring good cuttings will be obtainable. Plants raised from these will be better than those struck now. Old plants of Heliotrope should be potted and cuttings be rooted from which to propagate in the spring. Mesembryanthemum, Centaurea, Tropæolum, Petunias, Salvias, &c., all strike very readily, but Alternantheras, Iresines, and Coleus require a little heat to cause them to form roots quickly. Cuttings of Phlox decussata struck now in cold frames and planted out next spring will make dwarf flowering plants during the summer, and these are often preferable to taller plants obtained by simply dividing the roots in the border. Cuttings of the best coloured hybrid Pentstemons and others of P. Menziesii Newberryii should now be rooted. Plants raised every year are better than old plants that have survived the winter. A fortnight or three weeks hence will be soon enough to propagate Violas and Calceolarias from cuttings.

THE KITCHEN GARDEN.

By J. GIBSON, Gardener to His Grace the Duke of PORTLAND, Welbeck Abbey, Notts.

Parsley being always in demand, care should be taken at all times to ensure that there shall be no break in the supply. In order to ensure this during winter, there must necessarily be some protection afforded against excessive rain, frost, and snow, and nothing provides this better than do frames. The best results are obtained from young plants which have been transplanted in early summer, grown on strongly, and lifted early in autumn and placed rather closely together in a cold frame. This lifting should be carried out in time for the plants to recover the shift and make good growth in their new quarters before winter sets in, thus allowing the earlier leaf-age to be gathered off in order to induce the formation of new leaves. When left until too late, the old leaves have to be used instead of fresh and crisp growths. The close-growing and finely-curled varieties are much the best for this purpose.

Winter Lettuces.—Continue to plant good batches of Lettuce to stand for winter supply. Put them out in such soil that the plants when lifted for transferring them to frames will have a quantity of soil adhering to their roots. Small quantities of seed may still be sown, and from the present time onwards I strongly recommend Commodore Nutt and Golden Ball as varieties that will "turn in" quickly and be most useful at about Christmas time if grown singly in pots. If the pots are placed on shelves in any of the fruit houses when the cold weather sets in, the plants will continue to grow usefully.

Mint.—Dibble some young, healthy, and clean tips of Mint thickly into 6-inch pots and also in boxes. These, grown in an intermediate house later on, will yield a far better supply than would be obtained by lifting old roots from the open ground and forcing them in the usual way. Tarragon may be treated in the same manner.

THE HARDY FRUIT GARDEN.

By W. A. COOK, Gardener to Sir EDMUND G. LODER, Bart., Leonardslee, Sussex.

The Protection of Apples, Pears, and Plums is very necessary this season, as the birds are attacking them badly, and they do not finish one fruit first, but seek out all the best fruits and begin to eat them, the wasps and other insects doing the rest. All the best varieties of fruit should have a net thrown over them. If a large net be cut up to the requisite sizes, the pieces will last for several seasons, and will also serve for protecting bush and standard Cherry trees earlier in the season. Trees growing against walls are, of course, much easier protected, and for them it is not necessary to cut up the netting. Protection should be afforded without delay, remembering that it is useless to grow fruit to a certain stage and then neglect it. Autumn fruiting Raspberries will require to be protected with wasp-proof netting. These Raspberries should be given a plentiful supply of liquid at the roots during hot weather; they respond very readily to liberal feeding, and a good supply of such fruit is very appreciable. The variety Belle de Fontenay appears to be the best of this section. If Plums are not carefully protected they will soon become a prey to wasps, especially the varieties Coe's Golden Drop, and Jefferson's.

Mulberries should be gathered as soon as they turn colour or the birds will have them. These trees, with their dense foliage, generally harbour a quantity of birds. The fruits are very good after bottling, and afford a nice change in winter. The trees may be afforded a soaking with water, for there is something charming about old Mulberry trees, and they merit a little attention occasionally.

Quinces are fruiting finely this hot season, especially upon trees growing in moist situations. The fruits of these should be left on the trees until late in the autumn, they always hang well and are very ornamental.

Walnuts should be stored as soon as they will fall out of the shell readily. These nuts keep very well if packed in boxes of wood-dust or in some other material that will keep the moisture in them without being of itself wet. If there are no rooks about to steal them, the fruits are much better when allowed to fall from the tree when they have perfectly matured. Generally when the trees are thrashed they are not matured and do not in consequence keep so well.

Gathering Fruits.—Continue to gather fruits as they become fit. Several varieties of both Apples and Pears will now be ready, among Pears Marguerite Marillat, Souvenir du Congrès, Henri d'Amanlis, and the later fruits of Williams' Bon Chrétien will, at any rate, require looking over, selecting the earliest fruits for gathering. A fruit should be very carefully lifted up in the hand from its pendant position to a horizontal one, when, if it is ripe, it will part very easily from its spur. Early ripening Apples will need treating in the same manner.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication *as well as specimens and plants for naming, should be addressed to the* **EDITOR, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Special Notice to Correspondents.—*The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.*

Illustrations. *The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c., but he cannot be responsible for loss or injury.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.*

Local News.—*Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

APPOINTMENTS FOR THE ENSUING WEEK.

SATURDAY,	Sept. 15	German Gardeners' Soc. meets.
MONDAY,	Sept. 17	Nat. Chrys. Soc. Com. meets at Essex Hall, Strand (3 p.m.).
TUESDAY,	Sept. 18	London Dahlia Union Exhib., Botanic Gardens, Regent's Park (2 days).
WEDNESDAY,	Sept. 19	Nat. Rose Soc. Autumn Exhib. at Hort. Hall, Westminster.
THURSDAY,	Sept. 20	*Evening News* Chrys. Exhib. at Hort. Hall, Westminster.

Average Temperature for the ensuing week, deduced from observations of Forty-three Years at Chiswick 57·2°.

Actual Temperatures.—

London.—*Wednesday, September* 12 (6 p.m.): Max. 71°; Min. 54°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—*Thursday, September* 13 (10 a.m.): Bar., 30·1; Temp., 66°; *Weather*—Fair, but overcast.

Provinces.—*Wednesday, September* 12 (6 p.m.): Max. 66° Guildford; Min. 55° East Coast of Scotland.

SALES.

MONDAY and WEDNESDAY—
Sale of Bulbs at Stevens' Rooms, King Street, Covent Garden, at 12.30.

MONDAY to FRIDAY—
Dutch Bulbs, at 67 & 68, Cheapside, E.C., by Protheroe and Morris, at 10.30.

TUESDAY—
Sale of Greenhouse plants at The Nursery, High Street, Clapham, by Protheroe & Morris, at 12.

FRIDAY—
Imported and Established Orchids, at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 12.45.

The Forest Trees of Switzerland. The ordinary tourist in Switzerland is so impressed by the sublimity of the mountains and their accessories that he pays little heed to the trees. He does not see that these often barren slopes have been denuded of their covering by the negligence and carelessness of the inhabitants, and yet the country is so dependent on timber for constructional purposes or for fuel that it might have been supposed that measures of protection and conservancy would have been taken long ago. Take, as an example, the slopes above Grindelwald and Zermatt, where remains of forests of the Arolla Pine (Pinus Cembra) still exist, and where many a storm-tossed veteran may still be met with. These are eminently picturesque, but it would be more satisfactory to see an undergrowth of seedlings of various ages springing up to replace them.

We do not say these do not exist, but they are not present in quantities anything like adequate to the future demand. It is comparatively rare to see young saplings, and no means are, or were, taken to protect the young seedlings from the browsing of goats, horses, and other animals. Near the Tête Noire are remains of magnificent Larches, but here, again, little foresight seems to be exercised. With the Red Spruce—Picea excelsa—the case is, or seems, different; more care appears to have been exercised in order to provide a continuous supply of timber, and a like remark probably may be applied to the Silver Fir. Remains of fine forests of deciduous trees, Oaks in particular, as in the district above Lausanne, are to be met with. On the lower grounds also noble Lime trees may occasionally be encountered as near Lausanne as Pregny, Prilly, Fribourg, Thun, and elsewhere. These trees often commemorate some historic event, and are accordingly cherished by the inhabitants. Striking and impressive as are these noble trees, they are, of course, of no value for forestry purposes, unless it be to show that soil and locality are favourable to the growth of trees. With the view of calling the attention of his countrymen to the need of afforestation, and of protection for what is still left, as well as with the intention of indicating to planters what are the most decorative trees to plant for pictural purposes, M. Correvon has recently published a volume entitled "Nos Arbres."* The author writes as an enthusiast, and occasionally soars into poetic heights.

As, however, he writes with ample knowledge of his subject, this may be forgiven, and, indeed, it may be said that the whole volume is pleasant to read by those to whom the language presents no difficulties. M. Correvon writes agreeably of historical trees, of the consequences of the reckless destruction of forests and the means to be taken to remedy the disasters and prevent their recurrence in the future. He then passes in review the principal trees of Switzerland, not confining himself to those that are native to the soil, but extending his purview so as to include those exotic trees that are hardy and which may be useful for purposes of replanting or for the sake of picturesque effect. The common Pear forms a large timber tree in the Valley of Engelberg, and its fruits are not to be despised when made into a compote. In Caulon Valais, as in the Jura, we have met with fine specimens both of Apples and of Cherries, so that it is clear that those who plant for utilitarian purposes only, need experience no difficulty in fulfilling their requirements, and the Spruce, the Silver Fir, the Cembra Pine, and the Larch are ready to hand for economic purposes.

* Geneva, Atar, Corraterie 12.

Our Supplementary Illustration to the present issue affords two distinct views of the Hollies growing in the Royal Botanical Gardens, Kew. One of the pictures shows a number of fine, naturally-grown specimens in the Holly collection; the other a portion of the unnatural-looking, severely-clipped specimens contained in the formal or Italian Garden near the Palm House. A glance at the two views is sufficient to show that for general decorative purposes the naturally-grown Holly is most to be admired. For special positions, the formal sugar-loaf-like specimens are allowable, but it is to be regretted that in too many gardens the only method of pruning that is practised upon Hollies is that of clipping the growths hard back, as if every tree was really part of a hedge. The result of this is to be seen in the very formal-looking trees that are to be found in most incongruous surroundings, where naturally-grown examples would have produced an excellent effect. For the decoration of the garden and pleasure grounds, the common Holly in its numerous varieties is the most useful of all evergreens, as it is capable of growing almost anywhere in the British Isles and in almost any kind of soil. The varieties afford great differences in the size, shape, and colour of the leaves, and in the size and number of spines. In some forms, such as atrovirens, Hendersoni, maderensis, nigrescens, Wilsoni, and Shepherdi, or Hodginsii, as it is often called, the leaves are large and more or less oval; in camelliæfolia they are often 5 to 6 inches long, 2 inches wide at the base, tapering at the apex to a point. In ovata they are medium sized and ovate, the largest being scarcely 2 inches long; in Donningtonensis the leaves are about 3 inches long and very narrow; in Handsworthensis they are very small, and in ferox, the Hedgehog Holly, intensely spiny. Many varieties have gold and silver variegated leaves as Golden Queen and Silver Queen. The Milkmaid Hollies, aurea medio-picta, and argentea medio-picta, have the centres of the leaves gold and silver-coloured respectively, while the margins are of deep green. In such sorts as camelliæfolia, nigrescens balearica, &c., spines are but seldom found, while many others are more spiny than the common type. Ilex Aquifolium is represented at Kew by about 80 varieties, a few of the handsomest specimens being I. A. nigrescens, 30 feet high and perfect in form; altaclarensis, 25 feet by 20 feet; Golden Queen, 15 feet high; camelliæfolia, upwards of 30 feet high; and platyphylla, 20 feet high. In addition to I. Aquifolium, numerous other species are represented by fine specimens, such as I. cornuta, I. crenata, I. dipyrena, I. integra, I. latifolia, I. opaca, and others. The collection of Hollies is to be found behind the Temperate House, and of most sorts there are two or more representatives. The larger specimens are grown on the outskirts of lawns, a circular patch of open ground, 10 feet in diameter, being left around each plant. The younger and smaller specimens are in large corner beds on the same lawns. Every second year they are examined, when the leaders are set right, and any necessary pruning done. This pruning consists of thinning out, rather than of cutting back shoots, the object being to prevent anything like a stiff appearance. The variegated varieties are examined annually for the purpose of removing branches that are not of the correct colour. The formal trained Hollies near the Palm House are pruned into shape once a year, the work usually being done in August. The pruning is performed with knives or secateurs, to avoid mutilating the leaves, as is done when shears are used. The largest specimens near the Palm House are of Ilex Aquifolium, the smaller ones being gold and silver-coloured varieties. All of these are very old plants, and men who have been at Kew for upwards of 30 years, state that they can see very little difference in the size of the specimens during the time they have known them, which shows what an amount of clipping Hollies may be subjected to without causing them serious injury. A descriptive account of the varieties of Holly which existed at that time, by the late Thomas Moore, with illustrations of the leaves of most of them, was commenced in the *Gardeners' Chronicle*, Oct. 3, 1874, p. 432, and completed in the issue for Nov. 11, 1876, p. 616.

An Autumn Rose Show.—We may remind our readers that the third autumn show, under the auspices of the National Rose Society, will be held in the Royal Horticultural Hall, Westminster, on Wednesday next, September 19, and will be for one day only. An interesting feature of this year's show will be the class for "hips" and foliage of nine distinct species or varieties of Rose. Some Roses, of which R. rugosa is an excellent example, have exceedingly decorative fruits, and the exhibits will be instructive to the public. The President's cup will be awarded in this class.

BOTANICAL MAGAZINE.—The following plants are described and figured in the number for September.

FICUS KRISHNÆ C. DC., tab. 8,092.—A species nearly allied to F. bengalensis. Its native habitat is not known, the cultivated examples having arisen from a branch obtained from a private garden in Calcutta. It is described as a small tree with grey bark, and is especially remarkable on account of its cup-shaped leaves, having the upper surface of the leaf outside; the inside of the cup thus being formed by the under side of the leaf. Interesting particulars of this new species, which the Indians are said to invest with a sacred character, are given by Dr. PRAIN, and a botanical diagnosis is provided by Mr. C. DE CANDOLLE, whose plant formed receptacles in 1905.

CATASETUM GALERITUM VAR. PACHYGLOSSUM, tab. 8,093.—This is a variety differing from the type (as first described in the *Gardeners' Chronicle* by REICHENBACH in 1889, vol. 1, p. 73), in having the front lobe of the lip nearly square, exceedingly thick and obtuse-angled, with very thick borders underneath, leaving a groove in the middle. The figure here given has been prepared from specimens received from Sir TREVOR LAWRENCE, Bart., in February last, and the description is by Mr. R. A. ROLFE.

RIBES VIBURNIFOLIUM, tab. 8,094.—This is a species from Lower California and Santa Catalina Island. The plate here given has been prepared from a plant growing at Kew on a wall in the herbaceous department, where it has grown to a height of 7 feet. Mr. S. A. SKAN describes the plant as a straggling, evergreen shrub, which flowers in March at Kew, and its brilliant red berries persist until the succeeding year.

LINOSPADIX MICHOLITZII, tab. 8,095.—See Mr. RIDLEY's description in *Gardeners' Chronicle*, September 7, 1895, p. 262.

CEREUS SCHEERII, tab. 8,096.—Mr. N. E. BROWN describes this species as having been discovered by Mr. J. POTTS, near Chihuahua, in Mexico, and sent by him to Mr. FREDERICK SCHEER, of Kew, prior to 1850. The plant flowered in 1900 and during the two succeeding years, but subsequently died. A note from the late director of Kew Gardens, Sir W. T. THISELTON DYER, K.C.M.G., states that FREDERICK SCHEER was an independent botanist who for some time resided at Kew and particularly devoted himself to the study of Cactaceæ. He published in 1840 an excellent account of Kew under the title of "Kew and its Gardens." This and other actions were largely effective in averting the breaking up of the collections which had been contemplated, and in their being taken over by the nation from the Crown.

FLOWERS IN SEASON.—Amongst flowers that have been in season during the past month are Montbretias, and, in gardens where they are cultivated successfully, the bright yellow and deep orange-coloured flowers have been produced in greater profusion than usual. A box of flowers sent us by Messrs. WALLACE & Co., Colchester, represent some of the best and most recent varieties raised by Mr. G. DAVISON, of Westwick Gardens, Norwich, who has succeeded in obtaining such excellent and distinct varieties that they form a strain greatly superior to those previously in cultivation. The best of these, and indeed the best Montbretia we have seen, is the variety Prometheus, which grows from 3 to 4 feet in height, and has much branched inflorescences of deeply-coloured flowers, each of which is 3 inches or more across. They are of rich orange colour, with crimson markings at the centre. King Edmund is a rich yellow variety, marked with deep brown-coloured spots inside, and deeper yellow outside. Westwick is a distinct variety, having a ring of crimson colour encircling the clear yellow-coloured centre. The other parts of the petals are of bright orange red on the interior, and deep red on the exterior. Some of the flowers are 3 inches across, and the petals are of good width. Ernest Davison is marked in the centre much in the same way as the previous variety, and the flowers open until they are quite flat; in colour they are a deeper shade of orange than some others, and the exterior is flushed with red. Hereward has much recurved flowers, of pale orange colour. St. Botolph has pure yellow flowers of very large size, but the yellow deepens into orange on the exterior. This variety is described as growing 4 feet high. The deepest coloured of all the varieties is one known as Lord Nelson, and its shading of orange-red and crimson affords a fine contrast to the yellow varieties, such, for instance, as Lady Hamilton, whose yellow blooms have only a suspicion of reddish-orange colour in the centre. This last mentioned variety is among the most charming. Many gardeners complain that Montbretias do not succeed well in their localities, but in districts where the older varieties do succeed, as, for instance, in the Isle of Wight, where they appear in almost every cottage garden, these newer sorts being so extra vigorous may be expected to thrive even more perfectly.

FIG. 81.—MECONOPSIS PELLA FLOWERING IN THE EDINBURGH BOTANIC GARDENS FOR THE FIRST TIME IN BRITAIN.

(For text see page 198.)

NEW INSECT PEST ON LARCH.—The Board of Agriculture and Fisheries desire us to draw attention to the occurrence on the Larch of an insect, hitherto unrecorded, in destructive abundance in this country. The insect in question (Nematus Erichsonii) is a species of sawfly, the larva of which bears considerable superficial resemblance to the Gooseberry caterpillar, and to the caterpillar of the Pine sawfly. The larvæ are about three quarters of an inch long and possess 20 feet. They feed upon the leaves of the Larch from about the middle of July till the end of August. At the present time, therefore, few larvæ are to be found, but trees that have been attacked can be readily distinguished by their more or less leafless condition, and amongst the moss, grass, and leaves underneath such trees the brown cylindrical cocoons will be discovered. Where this is the case the surface-covering of the ground should be collected and burned. So far, serious damage has only been reported from Cumberland, where, however, the health if not the life of an extensive Larch plantation is in danger. It is of the utmost importance that outbreaks should be discovered at an early stage, so that they may be suppressed while still of restricted extent. The Board are preparing an illustrated account of the insect, which will be published in the October issue of their Journal.

PREVENTION OF CORRUPTION BILL.—"This measure received the Royal Assent three weeks ago, and will become operative on January 1, 1907 . . . . There can be no doubt that a measure of this kind has for long been needed. Many men who have been successful in retail business—including, unfortunately, a few persons connected with the trade in drugs—have owed a large portion of their prosperity to the systematic 'tipping' of butlers and other domestic servants. Large commercial contracts have been obtained from public councils and local authorities because the contractors have 'greased the palm' of the salaried officers whose duty it is to ensure that the ratepayers' money is well spent. There are many men in high positions who have at some time or other neglected their duty to their employers for the sake of gain; and it is to be feared that not all buyers in the employ of commercial firms can be regarded as wholly incorruptible. In some instances the acceptance by an employee of a secret commission has not been regarded as a moral delinquency, for the reason that the practice has been so common as to be 'winked at' by the employer. But it should hardly be necessary to point out that even connivance of this kind does not excuse corruptness of motive on the part of those giving and receiving bribes, and it will be of no avail as a defence to criminal proceedings under the new Act."—*Pharmaceutical Journal.*

NEW PUBLIC PARK FOR SHERBORNE.—The late J. K. D. WINGFIELD-DIGBY, Esq., of Sherborne Castle, had announced his intention of presenting a park to the town of Sherborne in commemoration of his son's coming of age on September 5, 1906, but, unfortunately, Mr. DIGBY died on Christmas Day, 1904. His son and heir to the estates has, however, generously redeemed his father's promise and given the land for the park. It may be remembered that a very successful pageant was held at Sherborne last year, with the result that a handsome sum was obtained after paying all expenses. With the greater part of this amount it was decided to lay out as a park the land between the railway station and the town, so generously given by the present owner of Sherborne Castle. The design submitted by Messrs. ROBERT VEITCH & SON, of Exeter, was accepted, and a most attractive park has been made, the work being executed under the superintendence of the late Mr. MEYER. About 150 tons of stone have been introduced to form rockeries, while water has been led in to form a lake, and many hundreds of alpine plants, shrubs, aquatic plants, and ornamental trees planted. The new park is to be known as the Pageant Gardens.

APPLES IN THE UNITED STATES.—A correspondent writing in *The Times* for September 7 gives some interesting particulars of an Apple census which has been taken in the United States, and relates that there are now 200,000,000 fruiting Apple trees in America, and the industry is still being extended each year. Orchards are being planted at a rapid rate in California, Washington, and Oregon. This season the American Apple shippers announce that they will send between 4,000,000 and 4,500,000 bushels of Apples from their ports, the bulk of which are to come to Great Britain. Tons of the Colorado Newtown Pippins will be sent into Covent Garden market, especially during the Christmas season. A well-known firm of fruit-brokers has secured a very large quantity of the largest and finest Apples of their class from this centre, and they will all come to London at Christmas time. These giant fruits will be packed in one bushel boxes, and it is estimated that the London buyers will readily pay 20s. a bushel for

them. Although all the orchards are sprayed, yet the grub of the codlin moth chiefly destroys on an average 20 per cent. of the crop. It is estimated that the lowest computable loss from this one pest alone is £4,000,000 per annum. In addition, it costs an average of 4d. to spray each tree. The American Apple-grower spends something like £3,333,333 on spraying. Despite these drawbacks, Apple culture is the most promising branch of agriculture in the States. The fertility of some of the fully-matured trees is remarkable. An observer in the Colorado Apple districts states that he has seen as many as 50 bushels of fruit gathered from one tree. The general average is a poor one against such a crop as this. In the Newtown growing districts 3s. and 4s. a bushel are paid for best Apples. It is said that in 10 years' time the Apple harvest of the United States will be doubled; nevertheless the home consumption trebles itself every ten years. Over-production is thus impossible.

BEES STUPEFIED BY POLLEN.—Our valued correspondent, Mr. W. E. GUMBLETON, in writing to us of an American single-flowered Dahlia, distributed by Mr. DREER, of Philadelphia, under the name of "Twentieth Century," states that the florets are persistent for twice as long as those of ordinary single Dahlias, and that the pollen has such an effect upon bees that they drop from the flowers to the ground in a quite stupid condition.

four other buds appearing in the axils of other leaves around the base of the flower stalk. The flower scapes are simple, bearing only one bloom, which rises just above the foliage, and is about one and a quarter inches in diameter. Probably, in older and stronger plants, the flower stalks will be longer, as shown in Dr. Prain's figure in the Calcutta *Annals*. The petals are of light blue colour. The stamens are numerous, with yellow anthers, while the filaments are of a dark purple colour, which give the flower the appearance of possessing a round purple disk at the base of the petals when first observed.

The plants were raised from seeds received from the Calcutta Botanic Garden, with other species of Meconopsis, early in 1904. A good percentage of the seeds sown germinated, and, when large enough to be handled, were pricked off into pans in much the same manner as adopted with other species, though, being smaller, they required rather more care. Some were left in these pans, while others were this year potted into small pots, but little appreciable difference could be observed in the strength of those grown by either method.

The mixture of soil used here is one of peat and sand, with a small addition of loam.

A cold frame with a northern exposure until the plants are well established is found to give the best results for this species.

Although this plant has previously been

and curly multifid tassels, and the frond a much larger, rather corymbiferous one, the whole having a peculiarly neat appearance. The term canaliculata has been applied owing to the frond forming a kind of half tube, or channel, due to the inward curvature of the side divisions, as shown in the illustration, by two sections, and from which it will also be seen that the frond narrows at its base. The variety is a noteworthy addition to the many extraordinary sports which have quite suddenly characterised this species in the last few years after decades of cultivation on perfectly constant lines. It has been Mr. May's good fortune to introduce the majority of these as sports originating in his own nursery. The abundance of these varieties occurring within so short a period suggests that Prof. de Vries' theory of the occasional occurrence of periods of mutation or sudden change in specific forms is not without foundation. *C. T. Druery, V.M.H., F.L.S.*

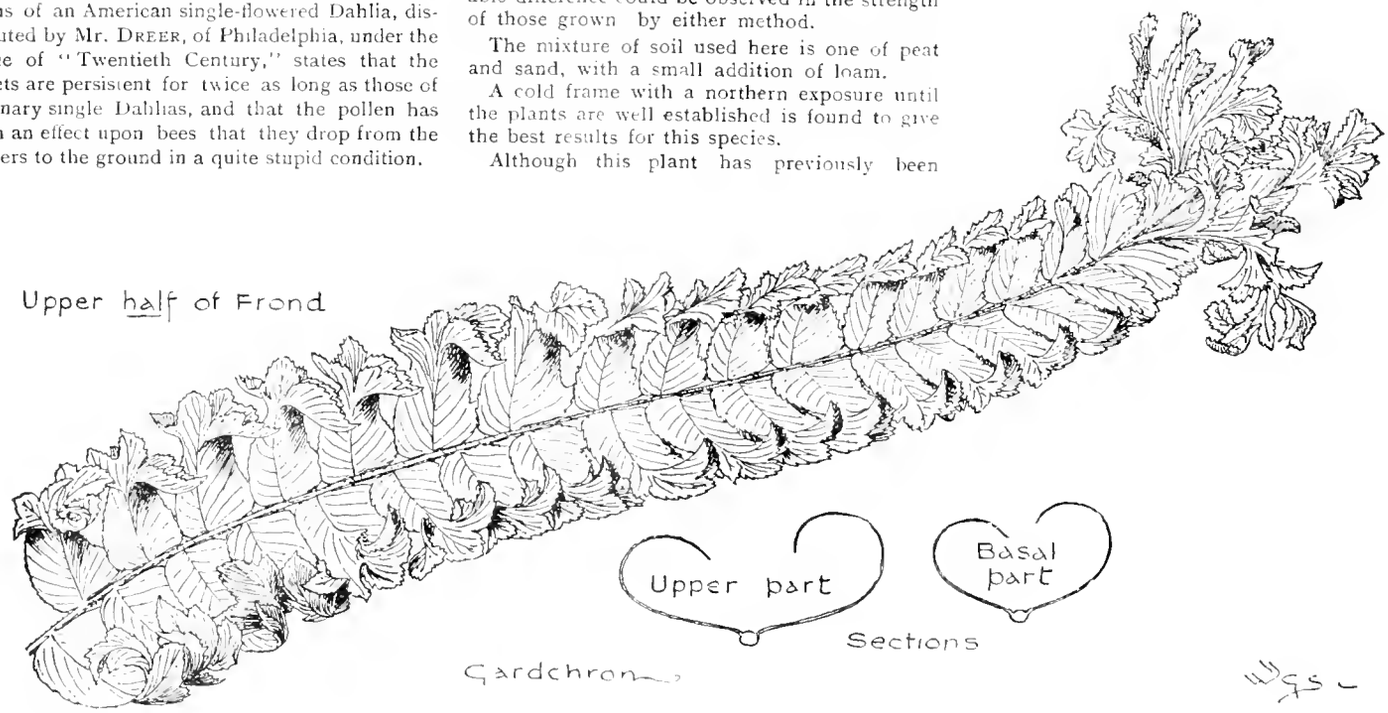

FIG. 82.—MIDDLE AND DISTAL PORTION OF THE FROND OF NEPHROLEPIS EXALTATA VAR. CANALICULATA.

Publications Received.—*Guide to the Experimental Plots at the Rothamsted Experimental Station, Harpenden (1906)*, price 1s.—*The Midland Agricultural and Dairy College*—reports on experiments with crops and stock.—*Kew Bulletin*, containing among other matters, an article relating to diseased Apples and Melons from the Cape of Good Hope, notes on Sydney Botanic Gardens, Irish Gardens, and descriptions of new plants.—*Travaux Scientifiques de L'Université de Rennes, Tome II., 1905.*—*A Year in my Garden*, by Mrs. Arthur Tuckett, published by Melville & Mullen, Melbourne, price 5s.—*A Book of English Gardens*, by M. R. Gloag, illustrated by Katherine Montagu Wyatt, and published by Methuen & Co., price 10s. 6d.—*Practical Trapping of Vermin and Birds*, by W. Carnegie, published by L. Upcott Gill, price 1s.

MECONOPSIS BELLA.

THIS species of Meconopsis is distinct from all others of the genus, and is the only known representative of the group Bellæ. It is a very diminutive little plant of perennial habit, with small radical leaves about an inch or little more in length. These are deeply divided, and have been well described as Corydalis-like by Dr. Prain. They form a small cushion upon the Prain. They form a small cushion upon the soil.

The plant now flowering here (see fig. 81, p. 198) has one opened flower, with

grown, this is the first occasion of its having flowered, so far as is known. Perhaps, with a race of plants raised from British-grown seed, the stock may become more naturalised to our climatic conditions, and consequently stronger. Should this be so the species will soon become more common in our gardens. It is figured in the *Annals of the Calcutta Botanic Garden* in part one of Vol. IX., and is a native of the Eastern Himalaya, at an elevation of 12,000 or more feet. *R. L. Harrow, Royal Botanic Garden, Edinburgh, August, 1906.* [See also an article by Dr. Prain on the species of Meconopsis which was published in the *Gardeners' Chronicle* for June 17, 1905.—ED.]

NEPHROLEPIS EXALTATA VAR. CANALICULATA.

THIS is a recent "sport" introduced by Mr. H. B. May which recently received an Award of Merit from the Floral Committee of the Royal Horticultural Society. It is quite distinct from the numerous other varieties of the species which have originated of late years, the fronds being not merely furcate or cristate, as in previous forms, but they are also symmetrically narrowed. The pinnæ are incurved, bearing somewhat contested

STRAWBERRIES IN 1906.

OWING to the late frosts and the general cold weather in spring time, picking did not commence as early in the season as is usual, and the dry weather during June and July caused the crops to finish rapidly. Many of the "King" berries were frosted, thus the early and the mid-season crops were ready almost simultaneously. Kentish growers appear well satisfied with the season's results, although at one time there was a glut. I find that the variety Sir J. Paxton still remains the favourite, but Royal Sovereign precedes it by about seven days and commands much favour. Laxton's Fillbasket has given great satisfaction, and "The Laxton" has also cropped freely, and, as one grower significantly remarked, "We don't eat them ourselves," the bulk of crop being the chief consideration. The dry season favoured this variety, which is remarkable for its cropping qualities. The Bedford Champion is under trial and will be a great gain in producing those "giant" berries which sell so readily in punnets. Mildew has been rather troublesome in North Kent. In dealing with our own field-grown plants, we crop a limited number only, as we grow principally for a supply of plants. Royal Sovereign

was free from mildew and gave us fine crops; the fruits from Sir J. Paxton were unusually large and handsome; President—still one of the best main garden sorts—was crippled by frost, and the fruits of Vicomtesse Hericart de Thury were smaller than is usual. Some of the older kinds were not so fine as they were in 1905, notably Goliath, Eleanor, Elton Pine, and Waterloo. The heaviest cropper was the pinkish white Louis Gauthier, some of the "king" berries being 2ozs. in weight, and the flavour was most refreshing; British Queen and Dr. Hogg both gave extra large berries; the quality of these varieties compensates for a small crop, as they are still far the best flavoured Strawberries. Of the newer varieties, Trafalgar produced fair results, but I do not think it has come to stay. Laxton's Fillbasket is a variety all gardeners should grow; the crop is enormous and the flavour very rich. The Bedford and Bedford Champion gave a few very large fruits, but have not yet made themselves at home with us; other growers, however, speak well of them. Reward is a very rich, mulberry-fleshed, late variety, but the crop is small with us. These three last named varieties may do better another year. The finest late Strawberry is Givon's Prolific, and I am pleased to find growers in all parts appreciate it, as I was the first to call attention to this remarkable variety, which begins to fruit after other kinds have finished. A client informs me he gathered berries weighing seven to the pound. The flavour is very rich and the leaves cover the fruit, an important point in hot weather. The plants crop for a long period, making our gatherings last over six weeks.

Messrs. Laxton are to be congratulated on their new "Laxton's Latest," an immense mulberry-coloured fruit of very rich flavour and of firm texture and one suitable for travelling. One berry furnished me with four bites (!) which gives some idea of the size of the individual fruits. This and Veitch's President Loubet render the growing of Waterloo unnecessary. Laxton's Latest must not be confounded with Latest of All, which I have discarded owing to its liability to attack by red spider and the fruits not ripening thoroughly. It is scarcely necessary to add that all these late kinds are greatly benefited by a good application of liquid manure directly the flowers have set, the stimulant to be applied well away from the centres of the plants. Old varieties of Strawberries "die hard," and we are asked at times for such old-fashioned kinds as Myatt's Eliza, Keen's Seedling, Black Prince, Laxton's Noble, and others. It is surely a waste of time and land to grow these old kinds, when in newer introductions we have all that can be desired in quantity of crop, vigour of plant, and flavour of berry.

The one lesson we have noted in the dry season of 1906 is, that in order to secure a good crop, deep cultivation of the soil and ample manurings at the time of trenching are essential. We have suffered much delay in the production of young plants by reason of the drought, in consequence of which the runners have not formed freely, but I am of opinion that planting any time in September will give favourable results. The occurrence of rain in certain districts causes growers in those parts to become anxious to have their new beds planted, although the soil may be dust-dry where the plants are grown. It would be far better for the planter to wait for well-rooted runners than to risk planting them when in an immature state.

One difficulty in writing on Strawberries is that the kinds vary on different soils. I have therefore confined my remarks to those varieties that are generally successful everywhere. *George Bunyard, Maidstone.*

NEW INVENTIONS.

A NEW PLANT STAND.

FIG. 83 illustrates an appliance known as Bound's Patent Telescopic Tripod Plant Stand for exhibiting or staging plants at flower shows or in the conservatory, &c. The principal advantage in this stand is its adjustability, for by its means the plant can be raised or lowered at will, and thus be exposed to the best advantage. It will be readily seen that the stand can be closed to occupy a small space, much after the manner of a photographic tripod, whilst its rigidity is remarkable. In one of the groups of Orchids shown at the R.H.S. meeting on Tuesday last, the plants were raised by this means. The makers are Messrs. Wm. Wood & Son, Ltd., Wood Green, N.

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

APPLE EARLY WHITE TRANSPARENT (see p. 154)—I have known this excellent variety for a period of more than 20 years, and I have often

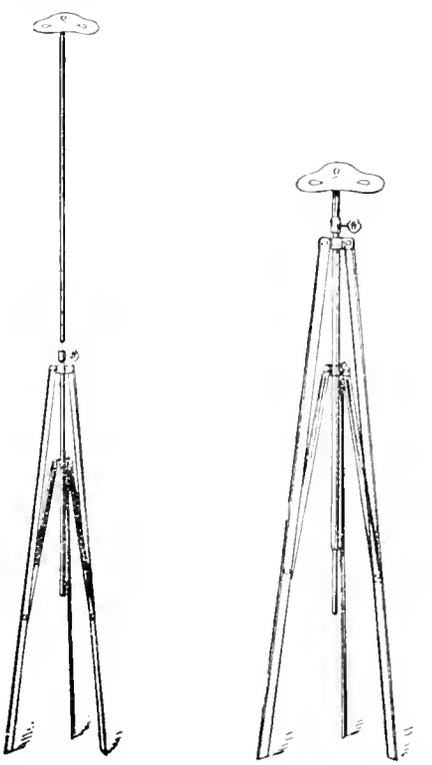

FIG. 83.—BOUND'S TELESCOPIC PLANT STAND, SHOWING ITS MINIMUM AND EXTREME HEIGHT.

wondered why it is not more largely grown; perhaps one reason against its culture is its white transparent skin which is easily bruised. This Apple is one of the few varieties introduced from Poland, but what name it bears in that country I do not know. It ripens during August and September. The tree is hardy and an excellent cropper, differing in the former respect from Calville Blanche, a French variety, whose growths are rather tender, and the tree does not succeed well except in warm localities. Early White Transparent keeps well, and I have had it in good condition as late as the end of February. One seldom hears of or sees that very large Russian kind Winintza Rambour. When well grown, fruits of this variety rival a large specimen of Peasgood's Nonsuch, and both the quality and appearance are first class. Many Russian varieties of Apples have the same white, waxy appearance seen in Early White Transparent. *W. H. Clarke, Oxon.*

PEACH CULTURE OUT-OF-DOORS.—I agree with Mr. Ward (p. 167), that "blister" in Peaches is, to a great extent, preventable, not by netting at the critical period to which *North Devon* alludes, but by having the trees in a clean, healthy condition in early spring-time and by giving them proper attention in early summer. Quite recently I inspected a number of large Peach and Nectarine trees in Mr. P. Veitch's garden at Exeter, and a healthier and more regularly-fruited lot of trees I do not wish to see. The foliage was ample and even, the fruit plentiful, large, and well-coloured, and the trees generally in splendid health. The large trees were trained on a wall 24 feet high, and this they had well covered to a height of 16 feet. The smaller trees were on a wall 8 feet high, and these were equally healthy and equally well-fruited. The larger ones had a clean stem of 5 feet. The Peaches were of the varieties Early Albert, Early Rivers, Waterloo, Hales' Early, Dymond, Sea Eagle, Noblesse, Princess of Wales, and Late Devonian; the Nectarines, Lord Napier, Precoce de Croncels, &c., all of which were bearing good crops of fine fruit. *A. H.*

——On page 184, *D.* states that the late Mr. Lindsay used to grow Peaches in these gardens without any protection, but I may say that for the past 10 years the trees have always been protected with a board coping, and with nets hung from the boards to the ground. Even with this slight protection in this favoured locality our trees are subject to "blister," though only slightly, and after the diseased leaves have been picked off the trees soon recover themselves. This year we have had a splendid lot of Peaches outside, numbering about 3,000 fine fruits. The very hot weather of the past few days completely spoiled many of the fruits, for wherever they were exposed they were burned by the sun. *Henry. H. Jones, Ditton Park Gardens, Slough.*

VITALITY OF SEEDS AND ROOTS.—Last year a clearance was made in a much overgrown and neglected garden that is surrounded by dense woodland, and had in fact become part of the woodland itself. It is known that before these operations were commenced, the garden had been untouched since the year 1860, at least, and that for certainly 25 years it had continued practically an impenetrable thicket, mainly composed of Rhododendrons. Following the admission of light and air consequent on last year's clearance, a great number of garden plants appeared this season, and many have flowered. I give the names of these plants below, from which it will be seen that there are annual, biennial, and perennial bulbous plants among them. The blue Lobelia, which is not hardy, is freely sprinkled amongst the grass and weeds. That this is the first appearance of these plants for many years is, I think, indisputable. The Rhododendrons, Brambles, &c., would permit nothing to grow under them, as those still standing testify, and the more open spots have been too keenly and constantly scrutinised by the keen eyes of botanists to allow any strange plants to appear unnoticed. Owing to the number of species occurring, I think it is safe to say that they cannot have been brought by birds and other natural agencies since last year's clearance; and as they have certainly not been accidentally introduced by man during the recent work there, I can only suppose that they are remnants of the original garden, and have lain dormant as seeds or roots for probably 50 years. This seems almost incredible, and if anyone can quote similar experiences or throw any light on the matter I shall be glad. The list of plants is as follows:—Lobelia (blue, bedding), Opium Poppies (Papaver somniferum), Œnothera biennis, Antirrhinums, Montbretia, Oxalis corniculata (and a yellow Oxalis, 8 inches high), Pansies (garden), Saxifraga granulata plena, Lilium, Mimulus luteus, M. moschatus, Leucoium æstivum, Polygonum cuspidatum, Pulmonaria sp., Black Currant (seedling), Lathyrus latifolius, Campanula latifolia and Pyrethrum aureum. *Harold Evans, Llanishen, near Cardiff.*

FERN-CULTURE FOR TOWN DWELLERS.—In *The Times* of August 25 Mr. Francis George Heath contributed an article, under the above heading, in which, after dilating on the beauty of our native wild Ferns, he advocates their purchase from street hawkers. Naturally such an incitement to the vandalism which all true Fern lovers deplore has evoked protests from several quarters, which Mr. Heath imputed to a misconception of his intention and ignorance of Fern culture, the latter since one of the correspondents maintained that the plants would not flourish. Obviously, however, such advice can only mean one thing, for if the peripatetic, Fern-hawking tramp or costermonger be encouraged by purchasing his plants, the demand can only be met by the denudation of our Ferny lanes, woods, and other favourable habitats, which are already so seriously raided in many places that stringent bye-laws are

needed for their protection from utter extermination, and numerous prosecutions have resulted. No one who has ever seen a collection of the far and away more beautiful types into which the normal forms have sported, could subsequently devote his pen to advocating, in book after book, the culture of the merely raw material whence the true Fern hunter derives his acquisitions. Mr. Heath's books, though with all-embracing titles such as the *Fern Paradise* in the first place and the *Fern World* in the second, treat alone of some forty odd specific forms. Two bulky volumes treat of the number cited, and yet in the *Fern Paradise*, under the head of the common Polypody, there is not the faintest allusion even to such an old and beautiful type as P. v. cambricum, the Welsh Polypody, and the same with all the other species, of some of which there are hundreds of distinct types, some merely curious and interesting, but most of them much more beautiful than the normal, though quite as hardy and as easily cultivated. Even of the forty odd species Mr. Heath only cites about half a dozen in his *Times* article as amenable to town culture, and these are already found in thousands of town gardens in monotonous profusion painful to the connoisseur. As Mr. Heath disclaims the intention of fostering the vandalism in question, we would ask him what is the meaning of the following extract from his *Fern Paradise*, p. 155: "Who could resist the temptation of . . . impounding yon jutting clumps of Fern roots Osmunda, Hard Fern, and Mountain Buckler Fern? . . . . Nature asks no questions, demands no penalties for our spoliation, but freely gives us up these wild and beautiful plants"? And again, p. 189, "No Fern is so plentifully vended in the London streets as are Polypody, for Epping Forest—that delightful strip of greenwood—furnishes the plant in thousands." That was published in 1875; where are the thousands now? What is required to cure this destruction is not the encouragement such pronouncements involve, but the education of the popular mind in the appreciation of the varietal forms. These, as we have said, are generally much more beautiful than the common ones, and their acquisition involves no vandalism since they can be obtained in a legitimate way by purchase from those who raise them from spores or by other propagative means. Most of them are procurable at very moderate prices, and would be, if popularised, cheaper still and within the compass of the poorest, especially as, once acquired, they are practically everlasting if properly cared for. No one who has once formed a collection of these ever grows the common ones again, and we have only to visit the Midlands and Black Country, where varieties are recognised, to see how fine specimens appear in cottage gardens and windows, while the common ones, except when rooted up wholesale by vandalistic villagers or peripatetic tramps for the market, are left severely alone. In conclusion, by way of contrast to the Fern-raiding tripper or other ruthless collector, we may point to the fact that the Fern hunter proper, *i.e.* the variety hunter, is happy if he secures a dozen plants in a week. Having secured them, he may be relied upon to propagate and distribute them, thus multiplying his acquisitions for the general benefit instead of rooting up wholesale with the almost assured prospect that not one in a thousand will become a "thing of beauty," much less "a joy for ever," as in the converse case. Our own last find was a tiny Blechnum (Hard Fern), 30 years ago, in a stone dyke on Exmoor. In two or three years 300 plants were distributed and a fine specimen still decorates our Fernery. *Chas. T. Druery, V.M.H., F.L.S.*

THE EFFECT OF ETHER ON PLANTS.—Numerous experiments have recently been made at the Cornell University to determine the effects of ether upon certain plants under cultivation. Aquilegia, Astilbe japonica and various bulbous plants were treated. Professor CRAIG, who superintended the experiments, reported that Lilacs yielded the best results; Cydonia japonica and Deutzias were less precocious in flowering; Astilbe proved very successful, while on such herbaceous plants as Aquilegias and Kindle has ether appears to have little or no effect. Lilium Harrisi (longiflorum var.) bloomed from one to three weeks in advance of the non-etherised bulbs. Rhubarb under the treatment was ready sooner than the untreated plants, and was far more abundant. Asparagus yielded profuse growth and was increased in stature, but was unusable.

SOCIETIES.

ROYAL HORTICULTURAL.

SEPTEMBER 11.—The ordinary fortnightly meeting of the committees took place on Tuesday last, in the Society's Hall, Vincent Square, Westminster. Dahlias of all sections constituted the dominant feature of the display, and the collections of these flowers produced an effect of the showiest character. Three varieties, all of them belonging to the Cactus type, were selected by the FLORAL COMMITTEE as worthy Awards of Merit. The only other award made by this committee was that of an Award of Merit to a variety of early-flowering Chrysanthemum: this type of the flower is now one of the features at these shows, and they may be expected to become more numerous at each succeeding meeting until November.

The ORCHID COMMITTEE recommended one Botanical Certificate and three Awards of Merit to novelties, the display of these plants being of less extent than usual.

The FRUIT AND VEGETABLE COMMITTEE did not make any award other than medals for collections of fruits, and a remarkable collection of Turnips.

The SCIENTIFIC COMMITTEE did not meet on this occasion.

At a meeting of Fellows in the afternoon, eleven new Fellows were elected, and Mr. T. S. Dymond delivered a lecture on "The Education of the Cottage Gardener."

Floral Committee.

Present:—W. Marshall, Esq., Chairman, and Messrs. H. B. May, Geo. Nicholson, Jno. Green, G. Reuthe, C. R. Fielder, Jno. Jennings, W. Howe, R. Hooper Pearson, Chas. Jeffries, Chas. Dixon, Jas. Douglas, R. C. R. Nevill, W. Cuthbertson, F. H. Jenkins, T. W. Turner, Geo. Paul, J. W. Barr, Ed. Mawley, and C. T. Druery.

Messrs. J. HILL & SON, Barrowfield Nurseries, Lower Edmonton, showed a splendid collection of Gloxinieæ, all the plants being beautifully developed specimens. There were rare species and choice forms of these beautiful ferns, such as G. decarpa, G. d. longipinnata, G. Speluncæ, the climbing G. Mendelli, G. rupestris, G. flabellata, G. semivestita and many others. (Silver Gilt Banksian Medal.)

Messrs. H. CANNELL & SONS, Swanley, Kent, showed some of the large petalled decorative Dahlias, among which we noticed the beautiful Souvenir de D. Donzon, a crimson scarlet variety, and one admirably suitable for a large flower bed. The same firm also displayed a collection of Gaillardias, a nice strain of Zinnias, and some good Chinese Asters. (Silver Banksian Medal.)

Messrs. G. PAUL & SONS, The Old Nurseries, Cheshunt, staged a miscellaneous collection of many interesting plants. Some were ornamental forms of trees and shrubs, others were shown for their fruits and flowers. Hypericum oblongifolium is a showy shrub, and produces its yellow flowers in plenty. The grand-leaved Oak, Quercus glandulifera (Alberti) was noticed, also the curious Rosa sericea pteracantha, with its large ornamental spines. Clerodendron trichotomum was nicely in flower. (Silver Banksian Medal.)

Mr. A. J. CLIMPTON, Station Road, Harpenden, Herts., showed a new bedding variety of Coleus named The Decorator. The plants are dwarf, with cut leaves, that are yellow with a deep green margin.

Messrs. W. WELLS & Co., Merstham, Surrey, showed summer-flowering Chrysanthemums from the open garden, the best of which were George Bowness (bronze), Rabbie Burns, Mme. Block (bronze), Treckwood Early (white), and Guinea Gold.

Mr. B. LADHAMS, Shirley, Southampton, showed a number of hybrids from Lobelia syphilitica.

Mr. L. R. RUSSELL, Richmond Nurseries, Richmond, filled one of the corners of the hall with a group of showy Clematis in small pots. They were plunged in baskets in their several varieties, which included Marcel Moser (mauve), Nellie Moser, Beauty of Worcester (blue), the beautiful C. Jackmanii rubens, the tiny white-flowered Viticella alba and V. rubra. (Bronze Flora Medal.)

Messrs. JAMES VEITCH & SONS, LTD., King's Road, Chelsea, displayed a finely-flowered batch of Leonotis leonurus—the Lion's Tail, and several specimens of the large flowering variety of Crowea latifolia. (Silver Banksian Medal.)

Mr. DAVID RUSSELL, Essex Nurseries, Brentwood, staged a very comprehensive collection of hardy Heaths, including many forms of our British species.

Messrs. JOHN LAING & SONS, Forest Hill, London, S.E., showed a number of small Codiæums (Crotons) in pots. They were well cultivated, and the varieties embraced most of the kinds usually grown.

Messrs. HUGH LOW & SONS, Bush Hill Park, Enfield, N., staged a bright group of Carnations, nicely arranged in tall vases.

Messrs. GUNN & SONS, Olton, Birmingham, set up a group of border Phloxes, in all the best kinds. (Silver Flora Medal.)

Several large exhibits of Dahlias were staged. Messrs. CARTER, PAGE & Co., 52-53, London Wall, E.C., showed over 100 varieties of these seasonable flowers. The collection included all the types save the show. Cactus kinds predominated, and these were arranged in baskets with a setting of Ferns, Grasses, sprays of Ampelopsis foliage, &c. At either end of the group, which ran the whole length of the hall opposite the clock, were single and pompon varieties. We have no space to enumerate the many varieties shown, but may remark that they included all the more notable kinds, and most of last season's novelties. (Gold Medal.)

Messrs. HOBBIES, LTD., Dereham Nurseries, Norfolk, showed a pretty exhibit of Dahlias arranged on fancy stands, and relieved with Ferns and other suitable greenery. H. Shoesmith, Mrs. MacMillan, The Editor, William Marshall, and other choice varieties were well displayed. Opposite the group, in tall stands, was a number of varieties of the large flowered "Pæony" type. (Silver Flora Medal.)

Mr. JOHN E. KNIGHT, Tettenhall Nurseries, Wolverhampton, arranged a very pleasing exhibit of Dahlias, using fancy bamboo epergnes and glass vases for their display. Many single flowers were also displayed on boards, and, taken together, the group was one of considerable beauty, and was certainly arranged to the best advantage. (Silver Flora Medal.)

Messrs. J. CHEAL & SONS, Crawley, showed single, show, Cactus and pompon Dahlias in great variety. Especially good were the single flowers. (Silver Banksian Medal.)

Mr. S. MORTIMER, Rowledge, Farnham, Surrey, and Messrs. J. STREDWICK & SONS, Silverhill Park Nurseries, St. Leonards-on-Sea, exhibited new varieties of Dahlias.

Messrs. BARR & SONS, King Street, Covent Garden, London, W.C., had an assortment of seasonable border flowers and pot plants of Nerine Fothergilli major, and a batch of the early flowering Crocus ornatus.

Messrs. WALLACE & Co., Kilnfield Nurseries, Colchester, exhibited many choice border flowers, among which were seen the large-flowered Montbretia Prometheus, and another named Hereward, of bright yellow shade.

Messrs. JOHN PEED & SONS, West Norwood, London, staged border flowers and hardy succulent plants.

Messrs. WM. CUTBUSH & SON, Highgate, London, N., put up a well-arranged exhibit of hardy flowers that embraced most of the best kinds now in season. (Silver Flora Medal.)

Mr. AMOS PERRY, Winchmore Hill and Enfield, Middlesex, showed hardy flowers and Nymphæas in variety. (Silver Flora Medal.)

Messrs. WARE, LTD., Feltham, staged a pretty assortment of border flowers, among which were noticed many old garden favourites. (Bronze Flora Medal.)

AWARDS OF MERIT.

Chrysanthemum "*Ethel*."—An early flowering border variety with light, buff-yellow coloured flowers, which measure about 4½ inches in diameter. The height of the plants shown was about 16 inches, and they were very freely flowered. Shown by Messrs. W. WELLS & Co.

Cactus Dahlia "*Gazelle*."—This is a very neat flower, composed of rather short florets, each slightly incurved towards the centre. For the type, this flower is somewhat formal, but very refined. The colour is a rich shade of mauve, with a white centre.

Cactus Dahlia Rev. J. Hall.—This is a large, spreading, somewhat thin flower, with narrow fluted and slightly twisted florets. The colour is of rosy crimson. This and the preceding variety were shown by Messrs. STREDWICK & SON.

Cactus Dahlia Hamlet.—A large flower, of which the florets are spreading rather than incurved. The colour is bright red. Shown by Messrs. J. CARTER & SON, Woking.

Orchid Committee.

Present: J. Gurney Fowler, Esq. (in the chair), and Messrs. Jas. O'Brien (hon. sec.), W. Boxall, W. Bolton, Jeremiah Colman, R. G. Thwaites, H. Little, W. H. White, W. H. Young, H. A. Tracy, G. F. Moore, Francis Wellesley, Harry J. Veitch, and Major G. L. Holford, C.I.E., C.V.O.

H. S. GOODSON, Esq., Fairlawn, West Hill, Putney (gr. Mr. G. E. Day), had a very effective and well-arranged group, at the back of which were graceful Palms, among which appeared the slender spikes of the bright yellow Oncidium varicosum, some exceptionally good forms of Lælio-Cattleya elegans, and a plant of the rare Dendrobium Williamsianum, with a spray of flowers somewhat resembling D. Phalænopsis, but, with white sepals and petals and a light violet-coloured lip. At one end of the group was a selection of Lælio-Cattleya bletchleyensis, at the other, several very fine forms of Cattleya Iris, and arranged with them were Odontoglossum crispum, Brassia brachiata, Miltonia Bleuana, various Cypripediums and Cattleyas, the brightly-tinted Lælio-Cattleya Massangeana Harry Goodson, which had previously secured an award of merit; L.-C. Parysatis, and others. (Silver Flora Medal.)

Messrs. SANDER & SONS, St. Albans, staged an extensive group, which included several of their dwarf and showy type of Cattleya Iris inversa, the variety amabile being a very finely coloured form with a large ruby-purple lip. Of the Lælio-Cattleyas, L.-C. Ingrami splendens was remarkable for its fine dark maroon-purple lip, and good forms of L.-C. elegans, L.-C. bletchleyensis, L.-C. callistoglossa, Cattleya Pittiana, C. Lord Rothschild, C. Mrs. J. W. Whiteley, and various good Cypripediums were included. Of botanical interest were a fine plant of Lælia monophylla, with over a dozen orange-coloured flowers; Stanhopea Wardii, Pholidota articulata, P. conchoidea, Cycnoches ventricosa (with a raceme of six singular flowers), and a good form of Cypripedium Fairrieanum. (Silver Flora Medal.)

Messrs. CHARLESWORTH & CO., Heaton, Bradford, arranged a very handsome group in the centre of which were twenty-five finely-flowered plants of their Cattleya Iris, which is a general favourite with all Orchid growers on account of the remarkable variation in the tints of the flowers, which are, however, always showy. Some of the plants staged had bronzy orange sepals and petals, and carmine-crimson lip, others reddish-olive sepals and petals and ruby-purple lip, and no two were exactly alike. So handsome and dissimilar are the forms of Cattleya Iris, that eight distinct varieties have already received awards at the Royal Horticultural Society. On each side of the Cattleyas were selections of the rosy-lilac, fringed-lipped Brasso-Cattleya Mad. Chas. Maron, with two of the darker rose B.-C. Heatonensis and one of the singularly coloured Brasso-Lælio-Cattleya elegans-Digbyana. Among Lælio-Cattleyas were two dark forms of L.-C. Dominiana and several of the finely-coloured L.-C. Illustris, L.-C. Alcyone, Cattleya Vulcan, C. Germania, and of species noted were Trichopilia Turialva, Mormodes pardinum unicolor, Anguloa eburnea, and various Odontoglossums and Cypripediums. (Silver Flora Medal.)

Messrs. HUGH LOW & CO., Bush Hill Park, Enfield, had a good group, principally of species and varieties. Lælia purpurata Duckworthi was a very pretty form, nearly an albino, the white flowers having only a veining of purple on the lip. This variety is said to always flower at this season. At the back of the group were the graceful spikes of Oncidiums, including O. varicosum, O. incurvum O. microchilum, and a distinct form of O. Forbesii, with sparsely-spotted, yellow lip. Odontoglossum bictoniense album was represented by its best form, and Cattleya Gaskelliana alba, C. guttata, C. Loddigesii albens, C. Minucia, C. St. Gilles, C. Iris, and others were included. Of Cypripediums, C. Youngiano-superbiens and C. Lawrenceanum Hyeanum were the best.

JEREMIAH COLMAN, Esq., Gatton Park, Reigate (gr. Mr. W. P. Bound), showed a pretty hybrid between Cattleya bicolor and C. Iris (bicolor × Dowiana aurea), in which the form and size have naturally reverted towards C. bicolor, but with the bright colouring of C. Iris. The sepals and petals were light purplish brown, and the lip purplish-crimson, with a slight white margin.

FRANCIS WELLESLEY, Esq., Westfield, Woking (gr. Mr. Hopkins), again showed the noble Brasso-Cattleya Mrs. Francis Wellesley, illustrated in the *Gardeners' Chronicle* on June 30 last, and which still holds the record for size and the delicacy of its pretty rose tint. The finely-displayed, fringed labellum was still finer than when last shown; also Lælio-Cattleya Duvaliana Westfield variety, with sepals and petals white, tinged with pale lilac; lip pale yellow at the base and with glowing purple front; also the pretty L.-C. Mrs. de Vere Beauclerk. (See Awards.)

AWARDS.

AWARDS OF MERIT.

Lælio-Cattleya Sunset (L. Jongheana × C. Percivaliana), from Major G. L. HOLFORD, Westonbirt, Tetbury (gr. Mr. H. G. Alexander). A very charming hybrid, with flowers nearly as large as C. labiata, the labellum being formed like C. Percivaliana, but improved by the pretty undulate edge of L. Jongheana. Sepals and petals broad and flat, of a delicate pale lilac tint, the veining being darkest. Lip clear, bright orange colour with a small, dark, bronzy-red blotch and several radiating, short lines in the centre. Margin white, with a narrow pale rose edge much crimped.

Lælio-Cattleya Mrs. de Vere Beauclerk (L.-C. Ingrami × C. Trianæi), from FRANCIS WELLESLEY, Esq., Westfield, Woking (gr. Mr. Hopkins). A very handsome hybrid with well-rounded flower, the petals of which are very broad, and the whole flower finely tinted. Sepals and petals white, tinged and slightly veined with rosy-lilac, the petals crimped on the outer half and rather darker in tint than the sepals. Disc of the lip dark orange, with minute spots and lines of red-brown at the base. Front claret-purple, with darker lines radiating from the orange-coloured disc.

Lælio-Cattleya Woodfordiensis (L. crispa × L.-C. C. G. Roebling) (L. purpurata alba × C. Gaskelliana), from J. GURNEY FOWLER, Esq., Glebelands, South Woodford (gr. Mr. J. Davis). A very bright and effective hybrid, in which three fine species unite, the result being a floriferous plant with flowers much resembling those of L.-C. exoniensis, but larger. The finely-grown specimen had two spikes of three and two flowers respectively. Sepals and petals white, tinged with rose; the showy front of the lip ruby-purple, with lavender margin.

BOTANICAL CERTIFICATE.

Polystachya grandiflora, from Sir TREVOR LAWRENCE, Bart., Burford (gr. Mr. W. H. White). A very extraordinary species from tropical Africa, and the largest of the genus. The flowers are produced on upright spikes, and follow in succession, about an inch and a half long, wax-like in texture, whitish with purple markings on the lip and purplish tinge on the outside of the sepals.

Fruit and Vegetable Committee.

Present: Jos. Cheal, Esq. (in the chair), and Messrs. S. Mortimer, Alex. Dean, Geo. Keif, W. Pope, R. Lye, H. Markham, Horace J. Wright, W. Barnes, J. Davis, John Lyne, Geo. Reynolds, J. Jaques, P. Tucker, W. Poupart, H. Somers Rivers, Owen Thomas, and A. H. Pearson.

There were several miscellaneous exhibits before the Committee, but none received an award. Mr. J. CROOK, of Forde Abbey Gardens, Chard, sent haulm and gathered pods of culinary Peas Autocrat and Gladiator, the Peas being in good condition for the kitchen. These had been shown to illustrate how the Pea mildew had been destroyed by spraying with a fungicide. Mr. F. M. BRADLEY, Church Street, Peterborough, exhibited a white or cream-coloured Cucumber; several varieties of Apples were shown, also a good dish of Doyenné Boussoch Pear, and a Melon came from the Society's gardens at Wisley, but it had little flavour to recommend it.

Messrs DOBBIE & Co., Rothesay, N.B., staged a remarkably good collection of Turnips, in about 60 varieties. The fine quality of the roots was freely commented upon, and the heavier rainfall of Scotland this summer was no doubt largely responsible for such a splendid show. The display was very representative, all classes of this important vegetable being included. Perhaps the finest of all was Dobbie's Model White, a beautiful white Turnip of perfect round shape, solid and with little tap root. A golden-coloured variety forming a good companion to this was Dobbie's Golden Ball, it being almost a replica, save in colour. Cattell's Silver Ball and White Globe are good white varieties. Then there were "green tops," Stone Marble, Top Stone, All-the-Year-Round, and others equally as good; "purple tops," the Cowhorn type such as Long White Meaux, and Long Green and Long Red Tankard; varieties that were concave beneath and with scarcely any tap root, such as Yellow Perfection; the so-called black Turnips, resembling nothing so much as dark-skinned Parsnips, such as Chirk Castle, Black Stone and Black Long, and the grey Turnip, Grey Morigny, &c. In addition were many ornamental kinds such as the pretty Scarlet Kashmir and Prince Engalitscheff, the latter having wavy stripings of violet on a yellowish ground. (Gold Medal.)

Miss M. H. DODGE, Loseley Park, Guildford (gr. Mr. Steward), showed two dozen varieties of Potatos, all clear of skin, and of large size, perhaps too large for the best culinary use. The varieties embraced most of the new sorts that were prominent during the recent boom. (Silver Banksian Medal.)

The Rt. Hon. WALTER LONG, M.P., Rood Ashton, Trowbridge (gr. W. Strugnell), showed a collection of indoor and outdoor fruits. The exhibit, taken collectively, was a very fine one, and embraced Plums, Peaches, Melons, Pears, Cherries, Nuts, Apples, Tomatos, Figs, and Grapes. (Hogg Memorial Medal.)

Miss ADAMSON, South Villa, Regent's Park, N.W. (gr. Mr. Geo. Keif), exhibited a number of choice fruits, many of which were from pot grown trees. Melons, Grapes, Plums, Nectarines, Pears, &c., of good quality were included. (Silver Banksian Medal.)

Sir W. PEARSON, M.P., Paddockhurst, Worth, Sussex, showed nine large Melons, for which a Cultural Commendation was awarded.

NATIONAL DAHLIA.

SEPT. 6 and 7. In our last issue we were enabled to give the names of the prize winners in the principal classes. The exhibition may be said to be equal to the average standard of former shows of the society, the dry season notwithstanding, and the number of entries was but few short of the record number of last year.
